BEHAVIORAL HEALTH

Imminent Medicaid Enrollment Lapses after Inpatient Mental Health Treatment in Young Adults
Michael Abrams, The Hilltop Institute; Maryann Davis, University of Massachusetts Medical School; Eric Slade, University of Maryland, School of Medicine; Lawrence Wissow, Johns Hopkins Bloomberg School of Public Health

Presenter: Michael Abrams, Senior Research Analyst, The Hilltop Institute, mabrams@hilltop.umbc.edu

Research Objective: To discern observable factors that predict Medicaid enrollment discontinuities for young adults (18-26) discharged from an inpatient psychiatric stay.

Study Design: Maryland Medicaid administrative and public mental health system data were used to construct an analytic data set that summarized the following types of individual-level information: demographics (age, race, gender, urban/rural living status), enrollment status (families and children (F&C), Maryland Children’s Health Insurance Program (MCHIP), disabled, or foster care), mental health diagnoses (bipolar, schizophrenia, depression, or substance abuse diagnoses), pregnancy status; and lagged (i.e., past) outpatient mental health, primary care, inpatient somatic, and emergency department based somatic health care events. Contemporary variables were traced for 365 days following (post-discharge from) a specialty mental health inpatient event. Lagged events were summarized based on a 180 day pre-admission period.

Probit regression was used to test which observable factors were significantly correlated to post-discharge Medicaid enrollment discontinuities (i.e., days without coverage). Regression tree analyses were used to hierarchically diagram factors placing enrollees at risk for Medicaid discontinuities.

Population Studied: All Maryland Medicaid enrollees age 18-26 years were included in our analysis if they had a mental health system inpatient event in the period spanning October 2005 to September 2006 (n=1,176). This population roughly corresponds to 1.7% of young adults that age engaged in Medicaid as of September 2006. Forty-nine percent of our study population was male, 46% white, 47% black, and 55% were categorically disabled based on state or federal criteria related to medical assistance eligibility.

Principal Findings: Thirty-two percent of our population experienced an enrollment discontinuity in the year post discharge of at least 1 day, and 28 percent (reduced sensitivity by 4 percent) experienced a discontinuity of at least 30 days. Probit modeling significantly predicted discontinuity (Log likelihood=-596, chi-square= 286, df= 21, pseudo R-square=.19). Significant individual effects (p<.05) were: age of 18 or 20 increased the adjusted-odds of discontinuity by 8.7%, higher income increased those odds by 13%, pregnancy decreased those odds by 14%, F&C/MCHIP status increased those odds by 37%, lagged Medicaid discontinuity increased those odds by 17%, lagged primary care visits decreased those odds by 11%. Sensitivity analyses, including the regression trees and 30 day discontinuity events, largely confirmed those results.

Conclusions: Thirty-two percent of young adults engaged in Maryland Medicaid experienced enrollment discontinuities in the program within one year of inpatient care they received from the state’s public mental health system (which largely overlaps with Medicaid). Correlates to that discontinuity in health coverage are fairly straight-forward as follows: age “cliffs” of 18 or 20 years old (preceding redetermination for those in standard Medicaid or foster care), higher family income (>100 percent of poverty), absence of pregnancy, F&C/MCHIP status, past discontinuities, and lower rates of past primary care use.

Implications for Policy, Delivery, or Practice: Our results isolate observable factors related to
Discontinuity of insurance for low income, publicly insured, young adults with a history of serious mental health issues. Beyond the basic rules of eligibility, missed primary care visits are identified as a significant promoter of future Medicaid discontinuities.

Depressive Symptoms and 30-Day Hospital Readmission among Older Adults
Jennifer Albrecht, University of Maryland School of Pharmacy; Ann L. Gruber-Baldini, University of Maryland School of Medicine; Jon Mark Hirshon, University of Maryland School of Medicine; Clayton H. Brown, University of Maryland School of Medicine; Richard Goldberg, VA Maryland Health Care System; Joseph H. Rosenberg, University of Maryland School of Medicine; Angela C. Comer, University of Maryland School of Medicine; Jon P. Furuno, Oregon State University/Orgeon Health and Sciences University School of Pharmacy

Research Objective: Unplanned hospital readmissions among older adults are common and costly to the healthcare system. Beginning in 2013, the Centers for Medicare and Medicaid Services will reduce reimbursement to hospitals with high 30-day readmission rates. Patients with depressive symptoms may be at increased risk of hospital readmission and could provide a target population for interventions to reduce readmissions. This study quantified the association between depressive symptoms at hospital admission and 30-day unplanned hospital readmission among older adults.

Study Design: We conducted a prospective cohort study between July 1, 2011 and August 9, 2012. We measured depressive symptoms with the 15-item Geriatric Depression Scale within 72 hours of hospital admission and defined presence of clinically significant depressive symptoms as a score greater than 5. Three follow-up calls post-hospital discharge were used to assess incidence of 30-day unplanned hospital readmission, defined as an overnight stay at any inpatient facility that did not occur in the emergency department and was not previously scheduled.

Population Studied: Community-dwelling adults aged 65 and older who had been admitted to the general medical and surgical services of an urban, tertiary-care hospital. Exclusion criteria included a Mini-Mental State Examination score less than 15 and inability to communicate verbally or in English. All study participants provided informed consent.

Principal Findings: 3,492 eligible patients were admitted to the hospital during the study period. Of these, 750 patients were enrolled into the study. Mean [standard deviation] age was 73.2 [6.5] years, 49 percent were female, and 72 percent were Caucasian. Prevalence of depressive symptoms at hospital admission was 19 percent. Forty-eight percent of patients with depressive symptoms had ever been told by a doctor that they were depressed. Incidence of 30-day unplanned hospital readmission was also 19 percent. In our adjusted log binomial regression model, depressive symptoms were not significantly associated with increased risk of 30-day unplanned hospital readmission [relative risk [RR] 1.20; 95 percent confidence interval [CI] 0.83, 1.72]. Age [RR 1.03; 95 percent CI 1.00, 1.05], Charlson Comorbidity Index Score [a measure of aggregate comorbidity] [RR 1.07; 95 percent CI 1.01, 1.14], and greater than 2 hospital admissions in the past 6 months [RR 1.53; 95% CI 1.12, 2.09] were significantly associated with an increased risk of 30-day unplanned hospital readmission.

Conclusions: Depressive symptoms, while common in older adults, were not significantly associated with an increased risk of hospital readmission.

Implications for Policy, Delivery, or Practice: Given current incentives to reduce 30-day hospital readmission, these results suggest that interventions targeting those with depressive symptoms may not significantly reduce readmission rates. Hospitals wishing to target patient groups at highest risk of 30-day hospital readmission should focus on older adults with more comorbidities, and those with a history of recent hospital readmissions.

Depressive Symptoms and Non-Adherence to Discharge Instructions among Older Adults
Jennifer Albrecht, University of Maryland School of Pharmacy; Ann L. Gruber-Baldini, University of Maryland School of Medicine; Jon Mark Hirshon, University of Maryland School of Medicine; Clayton H. Brown, University of Maryland School of Medicine; Richard Goldberg, VA Maryland Health Care System; Joseph H. Rosenberg, University of Maryland School of Medicine; Angela C. Comer, University of Maryland School of Medicine; Jon P. Furuno, Oregon State University/Orgeon Health and Sciences University School of Pharmacy

Research Objective: Unplanned hospital readmissions among older adults are common and costly to the healthcare system. Beginning in 2013, the Centers for Medicare and Medicaid Services will reduce reimbursement to hospitals with high 30-day readmission rates. Patients with depressive symptoms may be at increased risk of hospital readmission and could provide a target population for interventions to reduce readmissions. This study quantified the association between depressive symptoms at hospital admission and 30-day unplanned hospital readmission among older adults.

Study Design: We conducted a prospective cohort study between July 1, 2011 and August 9, 2012. We measured depressive symptoms with the 15-item Geriatric Depression Scale within 72 hours of hospital admission and defined presence of clinically significant depressive symptoms as a score greater than 5. Three follow-up calls post-hospital discharge were used to assess incidence of 30-day unplanned hospital readmission, defined as an overnight stay at any inpatient facility that did not occur in the emergency department and was not previously scheduled.
Population Studied: Community-dwelling adults aged 65 and older admitted to the general medical and surgical services of an urban, tertiary-care hospital. Exclusion criteria included a Mini-Mental State Examination score less than 15 and inability to communicate verbally or in English. All study participants provided informed consent.

Principal Findings: Of 3,492 eligible patients admitted to the hospital during the study period, 750 were enrolled into the study. Mean [standard deviation] age was 73.2 [6.5] years, 49 percent were female, and 72 percent were Caucasian. Prevalence of depressive symptoms at hospital admission was 19 percent. Non-adherence to the medication domain ranged from 11-14 percent at each follow-up time. Non-adherence to follow-up appointments ranged from 6-11 percent, and non-adherence to lifestyle instructions ranged from 43-46 percent. In adjusted longitudinal models, depressive symptoms were significantly associated with non-adherence to medications over time [odds ratio [OR] 1.75; 95 percent confidence interval [95p CI] 1.02, 2.99]. In contrast, depressive symptoms were not significantly associated with non-adherence to follow-up appointments [OR 1.25; 95p CI 0.62, 2.52], lifestyle recommendations [risk ratio [RR] 0.94; 0.75, 1.17], or with a lower [less adherent] summary adherence score [cumulative odds ratio [COR] 1.17; 95p CI 0.78, 1.75]. Social isolation risk, defined as a score of less than 12 on the 6-item Lubben Social Isolation Scale, and number of medications prescribed at discharge were significant predictors of non-adherence to follow-up appointments, lifestyle modifications, and a lower summary adherence score.

Conclusions: Depressive symptoms were associated with non-adherence to the medications domain of the discharge instructions, but not to follow-up appointments, lifestyle recommendations, or overall non-adherence among older adults.

Implications for Policy, Delivery, or Practice: This study may help identify older patients at greater risk of non-adherence to discharge instructions.

Lack of Relationship of Patient Activation and Health Behaviors among Safety Net Patients
Mona AuYoung, University of California at Los Angeles School of Public Health; O. Kenrik Duru, UCLA School of Medicine; Ninez Ponce, UCLA School of Public Health; Hector P Rodriguez, UCLA School of Public Health
Research Objective: Self-management support has been especially challenging for primary care practices to integrate into busy practices, especially among small practices and safety net clinics. Patients must be engaged in goal-setting and must become activated in order for investments in self-management systems to work. Patient activation, a measure of a patient’s ability to self-manage his or her own health, has been used in studies of self-management of chronic conditions. We examine the relation of patient activation and patient physical activity and dietary behaviors, focusing on safety net clinics in the process of augmenting self-management supports for obese patients.

Study Design: English and Spanish questionnaires were mailed to eligible patients between April and June 2012. Measures included the patient activation measure (PAM-13) and health behaviors such as physical activity (categories of 10-minute increments from 0 to 60), fruit and vegetable consumption (at least three times weekly), and soda consumption (at least three times weekly). Other predictor variables were grouped into one of the following domains and added sequentially: 1) patient experiences at the clinic (Clinician and Group CAHPS), 2) patient health, and 3) demographics. Multivariate logistic regression models predicting physical activity and dietary behaviors were specified to examine the impact of these factors on the relation of patient activation and health behaviors.

Population Studied: A random patient sample (n=393) was drawn from clinic administrative databases if they had at least two clinic visits in the past year, were age 18 and over, and had a body mass index of 30 to 34. The analytic sample includes a total of 198 patients for an adjusted response rate of 55.3% after excluding questionnaires returned due to invalid addresses. Of these, 38.9% of responses were Spanish-language.

Principal Findings: The majority of patients (70%) were in the highest two of four activation levels. Chronically ill patients also reported higher activation levels, especially diabetics. In unadjusted models, patient activation was only related to the outcome of daily physical activity, where patients in the highest level of activation had 2.21 greater odds of being active for at least 60 minutes daily than less than 60 minutes daily (p<0.05). In the full model for physical activity, only high cholesterol (OR=2.36, p<0.05) and overweight status (OR=4.64, p<0.01) were statistically significant. Patients with higher education and non-Latino White patients had significantly greater odds of fruit and vegetable consumption than other racial and ethnic groups. For soda consumption, Spanish-speaking Latinos were less likely (OR=0.14, p<0.05) to regularly consume soda than other racial and ethnic groups.

Conclusions: In contrast to published literature, there is generally no association of patient activation and health behaviors among safety net patients from diverse backgrounds. However, more chronically ill patients report higher levels of patient activation. Those with high cholesterol may be more likely to be physically active as a part of treatment. Overweight individuals may be more active than individuals with other BMI because they face health consequences but are still closer to a normal BMI.

Implications for Policy, Delivery, or Practice: Future research should examine the sources of the discordance between patient activation and health behaviors among safety net patients.

Mental Health Services among Individuals with Developmental Disabilities and Co-occurring Mental Health Conditions

Alicia Bazzano, David Geffen School of Medicine at UCLA; Erica Schuster, Westside Regional Center; Jenna Jones, MPH, Westside Regional Center; Aga Spatzier MPH, Westside Regional Center; Uchechi Acholonu MPH, Westside Regional Center; Danise Lehrer LCSW, Westside Regional Center

Presenter: Alicia Bazzano, MD, PhD, Assistant Clinical Professor, Pediatrics, David Geffen School of Medicine at UCLA, abazzano@ucla.edu

Research Objective: Individuals with developmental disabilities lack access to mental health care despite estimates that up to 30-35% of individuals with developmental disabilities have co-occurring psychiatric disorders (dual diagnosis). Additionally, persons with dual diagnoses may be at higher risk for taking multiple psychiatric medications and psychiatric
hospitalization. Understanding who are people with dual diagnoses and what characteristics predict poor access to care could better target interventions to prevent negative outcomes. We aimed to describe characteristics of individuals with dual diagnosis and understand factors associated with obtaining care from a mental health provider and medication use.

**Study Design:** We performed a retrospective chart review of cases from the California Department of Developmental Services’ electronic database and, prior to review, case managers confirmed eligibility. We randomly sampled cases, abstracting demographics, developmental disability and mental health diagnoses, utilization of mental health services and psychiatric medication use. We used logistic regression to predict mental health provider use and medication use.

**Population Studied:** We included individuals with developmental disabilities in western Los Angeles County who met one of these criteria, indicating dual diagnosis: psychiatric diagnosis in chart, prescribed psychiatric medications, or care from a mental health professional.

**Principal Findings:** Cases (n = 362) were mostly male (66%), English-speaking (81%), and >26 yr (51%). Children comprised 12% and youth (14-25 years) comprised 37%. Cases lived at home (55%), independently (21%) or in institutions (24%). Race/ethnicity included white (42%), black (28%), Latino (19%) and others (11%). Insurance included Medicaid (55%), private (16%), Medicaid/Medicare (15%), and other/none (14%). Eighty percent had psychiatric diagnoses in charts, 78% took psychiatric medication, 73% saw mental health professionals and 12% had psychiatric hospitalizations in the past 3 years. Of those with psychiatric diagnoses, 81% took medications, whereas without diagnoses, 68% took medications. Ninety percent of whites with Medicaid took psychiatric medications, with 71% taking 2 or more (polypharmacy), whereas 77% of blacks with Medicaid took medications and 47% had polypharmacy. Of Latinos on Medicaid, 68% took medications and 50% had polypharmacy. Of whites with private insurance, 87% took psychiatric medications, and 62% had polypharmacy. Of blacks with private insurance, 57% took medications and 43% had polypharmacy and of Latinos with private insurance, 50% took medications and 12% had polypharmacy. Youth had significantly higher predicted probability of medication use (88%) compared to children (72%) and adults (71%), as did those living in family homes (89%) compared to independently (74%) or in institutions (77%). Latinos had significantly lower predicted probability of medications (67%) compared to whites (83%). Latinos (68%) and living independently (74%) or in family homes (78%) had significantly lower probabilities of having a mental health provider compared to Whites (84%) and institutionalized individuals (90%).

**Conclusions:** Among those with developmental disabilities, Latinos and Blacks--especially on Medicaid--receive different mental health care access and psychiatric medication usage as compared to whites on private insurance.

**Implications for Policy, Delivery, or Practice:** Further research should focus on overcoming barriers to mental health service access for people with developmental disabilities who are minorities and on Medicaid. Policies expanding access to mental health professionals for these groups should be explored.

**Contacts with Healthcare Providers and Mental Health Facilities Post-Release from Jail Among Adults with Schizophrenia**

Larry Alphs, Janssen Research & Development, LLC; Carmela Benson, Janssen Scientific Affairs, LLC; Carmela Benson, Janssen Scientific Affairs, LLC; John Fastenau, Janssen Scientific Affairs, LLC; Lian Mao, Janssen Research & Development, LLC; Lynn Starr, Janssen Research & Development, LLC

**Presenter:** Carmela Benson, M.S., Associate Director, Health Economics and Outcomes Research, CNS/Psychiatry, Janssen Scientific Affairs, LLC, cbenson5@its.jnj.com

**Research Objective:** To evaluate outpatient healthcare utilization and providers and facilities visited/contacted post-release from jail. We hypothesized a variable contact rate with providers and mental health facilities by study subjects post-release from jail.

**Study Design:** Subjects randomized as of 15March2012 to PRIDE (Paliperidone Research in Demonstrating Effectiveness), an ongoing, pragmatic, 15-month, randomized, active-controlled, open-label study of paliperidone palmitate compared with oral antipsychotic treatment in adults with schizophrenia, were included in this interim analysis. At baseline,
subjects completed the resource use questionnaire (RUQ), which collects socio-demographic information and data on outpatient/inpatient services, emergency visits (ER), emergency medical services (EMS), and contacts with the criminal justice system during two periods: 12 months before the last incarceration and after recent release from jail. Demographic and clinical characteristics, reasons for arrest/incarceration, resource utilization, types of providers, and mental health setting(s) were evaluated and described.

**Population Studied:** Adult, incarcerated schizophrenia subjects who had been recently released from jail.

**Principal Findings:** 340 subjects were included; mean age was 37.8 years (SD=10.51); 64.2% were black or African American and 33.0% white. Average total days of incarceration was 91.1 (SD=187.0); average days from jail release to study screening was 45.7 (SD=62.58). Post-release from jail, 41.1% had no insurance coverage, 7.4% of subjects enrolled in Assertive Community Treatment (ACT), and 11.4% participated in a jail diversion program. Among subjects released from jail, 33.8% were released on probation, and 23.0% on parole.

Post-release from jail, the percentages of subjects with provider visits were as follows: psychiatrist=77.9%, psychiatric nurse=10.4%, primary care physician (PCP)=27.0%, nurse practitioner (NP)=3.6%, nonspecialty nurse (NSN)=5.8%, psychologist =11.3%, and social/case worker (SCW)=36.2%. Community mental health centers (CMHCs) followed by self-help groups (SHGs) were the most visited facilities post-release from jail (CMHC=24.4%, SHG=19.3%); rehabilitation programs and the Veterans Administration (VA) were the least utilized (psychosocial=1.2%, vocational=0.9%, VA=0.6%). Mean rates of subject contact per month with a psychiatrist and a psychiatric nurse were 3.60 and 0.50, respectively. Subject visits to a non–psychiatric-related provider ranged from 0.09 to 2.40 per month (PCP=0.80, psychologist=0.30, NP=0.20, NSN=0.09, SCW=2.40). Facility mean subject contact rates ranged from 0.01 to 7.10 per month (VA=0.01, vocational rehabilitation program=0.05, psychosocial rehabilitation program=0.30, day hospital/treatment center=0.80, alcohol/drug counseling=1.30, CMHC=1.30, SHG=7.10).

**Conclusions:** This interim analysis showed variable contact rates and a higher percentage of subjects visiting a psychiatrist or a CMHC among other types of providers and/or facilities post-release from jail.

**Implications for Policy, Delivery, or Practice:** Post-release from jail, schizophrenia patients are unlikely to seek care and have health insurance coverage. Timely and appropriate access to mental health services post-release from jail may be crucial to maintain the psychiatric and functional conditions of patients and to avoid repeated revolving door detentions in jail. Coordinating prison-based care with outpatient mental health programs may improve the quality of care and may help with society reentry and reduce recidivism.

**Suicidality during the Postpartum Period**

Susan Bodnar Deren, Virginia Commonwealth University; Kimberly Klipstein, MD, Dept. of Psychiatry, Mount Sinai School of Medicine; Madeleine Fersh, MD, Dept. of Psychiatry, Mount Sinai School of Medicine; Eyal Shemesh, MD, Mount Sinai School of Medicine; Elizabeth Howell, MD, MPP, Helath Evidence and Policy Obs, Gynecology, and Repro. Science, Mt. Sinai School of Medicine

**Presenter:** Susan Bodnar Deren, Ph.D., Assistant Professor, Sociology, L. Douglas Wilder School of Govt and Public Affairs, Virginia Commonwealth University, smbodnar@vcu.edu

**Research Objective:** The primary objective of this study is to examine the association between suicidal ideation (SI) with postpartum depressive symptoms, demographic, and psychosocial characteristics in a racially diverse group of women during the first six-months postpartum. The secondary objective is to evaluate how various depression/anxiety instruments and scores, obtained 1-2 days postpartum, correlate with the odds of postpartum SI.

**Study Design:** Data were obtained from 2 postpartum depression prevention randomized controlled trials implemented at a large inner-city urban hospital. Both trials tested the same intervention: 1 trial enrolled self-identified black and Latina mothers, the other trial enrolled white and other minority women. All participants were surveyed prior to randomization (24-48 hours postpartum), at 3-weeks, 3-months, and at 6-months postpartum and answered a series of questions on socio-demographics, depressive
symptoms, clinical characteristics, and psychosocial factors. Depression was assessed using both the Edinburgh Postnatal Depression Scale (EPDS) and the Patient Health Questionnaire-9 (PHQ-9). The primary outcome for this study was suicidal ideation (SI), assessed using the suicide/self-harm questions from both the EPDS and PHQ-9. If a patient scored positively, to either one or both of the questions, over the course of the study, they were considered to demonstrate SI. The key independent variable, maternal depressive symptoms 24-48 hours postpartum, was measured with a modified (suicide question removed) version of the EPDS. A score of 10+ indicated possible depression. In order to ascertain how other psychometric measures might be associated with postpartum SI, we investigated how a modified EPDS score of 13+; PHQ-8 (10+ and 20+); and to measure anxiety, Generalized Anxiety Disorder 7-item Scale (GAD-7) (10+) were correlated with the odds of SI.

**Population Studied:** 1080 mothers who gave birth in a large tertiary New York City Hospital (2009-2010), recruited during their postpartum hospital stay. Eligible subjects were women age 18+, English or Spanish Speaking, had working telephones, and had infants whose birthweights were > 2500 grams and 5-minute Apgar scores > 6.

**Principal Findings:** Three percent of participants presented with SI. Of these, 6% had suicidal intent. Bivariate analysis revealed that scores of 10+ on the EPDS (39% vs. 13%, p<.0001), PHQ-8 (35% vs. 12%, p=.0002) and the GAD-7 (42% vs. 16%, p<.0001) were associated with SI. In adjusted multivariable models, women with postpartum depressive symptoms as compared to those without were more likely to present with SI (OR=2.43, CI=1.03-5.69). Being foreign born (OR=2.66, CI=1.16-6.11), antepartum complications (OR=3.63, CI=1.69-7.82), and depression history (OR=2.39, CI=1.06-5.39) increased the odds of SI. Heightened self-efficacy decreased the odds of SI (OR=0.52, CI=0.30-0.89). The EPDS, PHQ-8 and GAD-7 were all significantly associated with suicidal ideation in unadjusted multivariate analyses.

**Conclusions:** The findings from our study suggest that suicidality may be under-recognized in the postpartum period. Anxiety and depression were correlated with SI.

**Implications for Policy, Delivery, or Practice:** Findings suggest that early postpartum depression screening may identify women at risk for suicidal ideation during the six-month postpartum period. Our results suggest that increased education about depression, anxiety, and suicidal thinking by providers is warranted during the postpartum period.

**Reducing Emergency Room Visits and Hospitalizations among Patients with Behavioral Health Conditions: Lessons Learned from California’s Low Income Health Program**

Livier Cabezas, University of California at Los Angeles Center for Health Policy Research; Nadereh Pourat, PhD, UCLA Center for Health Policy Research; Xiao Chen, PhD, UCLA Center for Health Policy Research; Erin Salce, MPH, UCLA Center for Health Policy Research

**Presenter:** Livier Cabezas, M.P.Aff., Project Manager, Health Economics and Evaluation Research, University of California at Los Angeles Center for Health Policy Research, livier@ucla.edu

**Research Objective:** The study aims to assess the impact of offering comprehensive behavioral health services on the utilization of medical care among Low Income Health Program (LIHP) enrollees with a behavioral health condition (BHC). LIHP is a county-operated Medicaid Waiver demonstration project which expands coverage to eligible low-income adults effective July 1, 2011 through December 31, 2013. Under the Affordable Care Act (ACA), LIHP enrollees will transition to California’s Medi-Cal Program or to California’s Health Benefits Exchange (known as Covered California) in January 2014. Examining the effectiveness of providing comprehensive services in reducing expenditure and improving health outcomes is needed.

**Study Design:** Claims and enrollment data submitted by 13 participating counties and a consortium of 35 rural counties were used. Over 570,000 individuals enrolled in LIHP during the first program year (July 1, 2011-June 30, 2012) were included in the analysis. We identified individuals with any mental health or substance abuse diagnosis and assessed utilization patterns of these individuals compared to those without such diagnosis in logistic regression models. Services assessed included any emergency room (ER), hospitalization, and evaluation and management (E&M) visits. We also assessed difference in patterns of use...
when comprehensive behavioral health services were offered. Comprehensive behavioral health services are defined as substance abuse benefits or integrated medical and behavioral health care.

**Population Studied:** Adults between 19 and 64 years of age who were enrolled in LIHP during the first program year.

**Principal Findings:** Of all LIHP enrollees, 13.9% (79,930) were diagnosed with a BHC at some point during the first program year. Of this group, 64.3% had any E&M visit, over 28.4% any ER visit, and 14.1% had any hospitalizations. The rates of ER visits and hospitalization of these individuals were significantly higher than those without a BHC. After controlling for demographic and chronic conditions, those with any BHC had higher likelihood of hospitalizations and E&M and ER visits. In counties with comprehensive behavioral health services the likelihood of E&M visits was significantly higher for those with any BHC (OR=1.43) than those without (OR=1.14). In contrast, the likelihood of ER visits (0.77 vs. 1.26) and hospitalizations (0.86 vs. 1.43) significantly declined.

**Conclusions:** The findings provide unique evidence that any mental health and substance abuse diagnosis increase the likelihood of medical care use significantly. The findings also provide preliminary evidence that offering comprehensive behavioral health services such as substance abuse benefits or integrating medical and behavioral health services may reduce costly services such as ER visits and hospitalizations and improve primary care delivery.

**Implications for Policy, Delivery, or Practice:** The findings highlight the importance of efforts to integrate and coordinate behavioral and medical care services to improve patient outcomes and reduce costs. Efforts in offering comprehensive behavioral health services will be essential for the Medicaid Expansion and success of Health Benefit Exchanges under ACA. Additional research is needed to determine the implementation challenges of medical and behavioral care integration and ways to overcome these barriers. These efforts are particularly important within the safety net because these providers are likely to continue to serve newly insured populations under ACA.

### Hospital Readmission Among Adult Medical Inpatients with Mild Depressive Symptoms

Ramon Cancino, Jr., Boston University School of Medicine/ Boston Medical Center; Suzanne E. Mitchell MD, MSc, Boston University School of Medicine/ Boston Medical Center; Ekaterina Sadikova, Boston University School of Medicine/ Boston Medical Center; Jessica Martin MPH, Boston University School of Medicine/ Boston Medical Center; Brian W. Jack MD, Boston University School of Medicine/ Boston Medical Center; Larry Culpepper MD, MPH, Boston University School of Medicine/ Boston Medical Center; Brian W. Jack MD, Boston University School of Medicine/ Boston Medical Center

**Presenter:** Ramon Cancino, Jr., MD, Academic Fellow, Family Medicine, Boston University School of Medicine/ Boston Medical Center, ramon.cancino@gmail.com

**Research Objective:** Little is known about health care utilization, specifically early hospital readmission rates, in patients with mild depression. Therefore, we aimed to determine whether mild depressive symptoms are associated with hospital readmission within 30 days following discharge among adult inpatients on a general medical service.

**Study Design:** A secondary analysis was performed using data from the Project Re-Engineered Discharge (RED) randomized controlled trials. We used the nine-item Patient Health Questionnaire depression screening tool to identify patients with depressive symptoms. The primary endpoint was hospital readmission, defined as readmissions within 30 days of discharge. We also studied emergency department utilization and primary care physician follow-up appointment attendance rates. Poisson regression was used to control for confounding variables. We surveyed participants 30 days after the index discharge using items from the post-discharge RED questionnaire and the three-item Care Transitions Measure (CTM3).

**Population Studied:** 1,418 English-speaking, hospitalized adults from an urban academic safety net hospital.

**Principal Findings:** The unadjusted hospital readmission rate within 30 days of discharge was 19.6 readmissions per 100 mildly depressed subjects compared with 13 readmissions per 100 non-depressed subjects. For those with moderate to severe depression, the unadjusted hospital readmission rate within 30 days of discharge was 21.1 readmissions per...
Comorbid Depression and Substance Abuse in Safety-net Clients of Health and Community-based Agencies in Los Angeles: Clinical Needs and Service Use Patterns

Presenter: Evelyn Chang, M.D., M.S.H.S., Health Services Research Fellow, General Internal Medicine, University of California, Los Angeles, evelyn.chang@va.gov

Research Objective: Depression and substance use disorders (SUD) are common among low-income, minority adults who may receive services from health and other community-based sectors. Depending on the sector visited, this population may receive screening, treatment or referral for depression or substance use but rarely integrated services. Little is known about the level of comorbidity across a range of service sectors supporting safety-net clients or use of services for depression in the context of substance abuse comorbidity for clients across diverse community-based settings. This study describes clinical characteristics and service utilization for low-income, primarily African-American and Latino, adults with depression with and without comorbid substance abuse in under-resourced communities.

Study Design: The study uses baseline data from Community Partners in Care (CPIC), a Community-Partnered Participatory Research initiative to improve depression services in under-resourced communities in Los Angeles County. Clients were screened for depression (PHQ 8>=10) in primary care/public health (PC), mental health (MH), substance abuse (SA), and social services (SS), and other community-based settings such as churches and senior centers. Eligible depressed clients enrolled and completed a baseline survey (n=845). We conducted univariate and bivariate analyses to describe the sample and compare those with and without comorbid SA in clinical need and services utilization in the past six months.

Population Studied: Clients were recruited from community agencies participating in CPIC located in two under-resourced communities in Los Angeles County: Hollywood-Metro and South Los Angeles.

Principal Findings: Across sectors, 48.5% (n=407) had co-morbid substance use disorder (SUD); most (n=323, 79.4%) were receiving hospitalization when it is a secondary diagnosis. Future research should focus on determining the benefit of treatment on hospitalized patients who screen positive for mild depressive symptoms. Policymakers should support local and state legislation which would allow for optimization of care transition programs and legislation which provides coverage of outpatient behavioral health services scheduled for the patient at the time of hospital discharge.

Implications for Policy, Delivery, or Practice: First, the hospital discharge process should systematically address barriers to follow-up and medication adherence at the time of discharge. Second, depression screening in this setting may aid in identifying barriers to successful transitions in care. Third, our study calls attention to the fact that no study has studied the treatment of mild depression during an acute hospitalization.

Conclusions: A positive screen for mild depressive symptoms during a hospitalization is associated with less understanding of post-discharge plans and an increased rate of readmission within 30 days of discharge in an urban, academic, safety net hospital population. A positive screen for mild depressive symptoms (PHQ 8>=10) in primary care/public health (PC), mental health (MH), substance abuse (SA), and social services (SS), and other community-based settings such as churches and senior centers. Eligible depressed clients enrolled and completed a baseline survey (n=845). We conducted univariate and bivariate analyses to describe the sample and compare those with and without comorbid SA in clinical need and services utilization in the past six months.

Population Studied: Clients were recruited from community agencies participating in CPIC located in two under-resourced communities in Los Angeles County: Hollywood-Metro and South Los Angeles.

Principal Findings: Across sectors, 48.5% (n=407) had co-morbid substance use disorder (SUD); most (n=323, 79.4%) were receiving hospitalization when it is a secondary diagnosis. Implications for Policy, Delivery, or Practice: First, the hospital discharge process should systematically address barriers to follow-up and medication adherence at the time of discharge. Second, depression screening in this setting may aid in identifying barriers to successful transitions in care. Third, our study calls attention to the fact that no study has studied the treatment of mild depression during an acute hospitalization.

Conclusions: A positive screen for mild depressive symptoms during a hospitalization is associated with less understanding of post-discharge plans and an increased rate of readmission within 30 days of discharge in an urban, academic, safety net hospital population.
SUD treatment, but less than half (46.0%) had health insurance. Most (73.8%) had family incomes below poverty levels with no significant difference by presence of co-morbid SUD. Clients with co-morbid SUD were more likely than those without to be in transitional housing (21.3% vs 3.8%, p<0.001) and had a higher rates of arrests (39.9% vs 7.3%, p<0.001), 12-month depressive disorder (73.5% vs 53.8%, p<0.001), post-traumatic stress disorder (57.8% vs 39.9%, p<0.001), and mania/psychosis (60.8% vs 27.7%, p<0.001). A greater proportion of clients with both depressive symptoms and SUD went to the ER for any health problems (59.1% vs 46.7%, p<0.001) and were significantly more likely to be admitted for an alcohol, drug, or emotional problem than those without SUD (23.0% vs 7.9%, p<0.001). Clients with both depressive symptoms and SUD had more MH specialty visits (70.4% vs 50.6%, p<0.001) and fewer PC visits (65.6% vs 74.9%, p=0.006) than those without SUD. Those with comorbid SUD received depression services during 67.9% of visits to outpatient MH clinics, 65.0% of visits to PC, 73.4% of visits to SA agencies, 56.6% of visits to SS agencies, 44.6% of visits to churches, and 19.0% of visits to senior centers.

Conclusions: Half of low-income minority adult clients across health and community-based agencies with depressive symptoms were found to have co-morbid SUD. These individuals have significant psychosocial stressors, including lack of housing, insurance and arrests. Depressed clients with co-morbid SUD utilized emergency, MH, and SS agencies at higher rates than those without SUD and had higher admission rates.

Implications for Policy, Delivery, or Practice: The high prevalence of comorbid substance abuse across diverse agencies supporting safety net clients suggests that a community-wide approach may be needed to stabilize health and social outcomes for this vulnerable population.

Gender and Race/Ethnicity Differences in Mental Health Care Use during the Great Recession 2007-2009
Jie Chen, University of Maryland at College Park; Rada Dagher, University of Maryland, College

Presenter: Jie Chen, Ph.D., Assistant Professor, Health Services Administration, University of Maryland at College Park, jichen@umd.edu

Research Objective: The 2007-2009 Great Economic Recession is the longest recession in US history. The job loss and wealth reduction during this economic recession may have increased the risk of mental disorders and mental health utilization. Mental health utilization patterns during the recession may also differ by gender and race/ethnicity. This study examined the mental health care utilization before and during the recent economic recession by gender and race/ethnicity.

Study Design: Using Medical Expenditure Panel Survey 2004-2006 and 2007-2009, the study employed a cross sectional analysis to examine the changes in mental health care use (prescription drug use and physician visits treating depression or anxiety disorders) before and during the recent recession. Negative binomial regressions were used to estimate the association of the economic recession and mental health care use for females and males. Race/ethnicity and the interaction terms of the economic recession and race/ethnicity were examined to assess whether racial and ethnic groups had different utilization patterns under the economic recession.

Population Studied: Our analysis included adults aged 18 to 64 years old, who were diagnosed with depression (ICD9 = 296, 311) or anxiety disorders (ICD9 = 300). The total sample of females was 11,216, including 7,760 Whites, 2,034 Latinos, and 1,422 African Americans, and the sample of males was 4,799, including 3,590 Whites, 750 Latinos, and 459 African Americans.

Principal Findings: The recession indicator was significantly associated with higher prescription drug uses for both females (IRR=1.33, p<0.001) and males (IRR=1.14, p<0.05). The increment in prescription drug use was higher among white males compared to Latino males. The IRRs of recession indicators in the physician visits regression showed that males significantly reduced physician visits (IRR=0.70, p<0.01) during the recession. The reduction of physician visits was more substantial among the white males compared to Latino males. Females used more physician visits in the recession (IRR=1.11, p=0.22), but this association was not significant. Our model estimated that during the economic recession, prescription drug use for mental diseases increased by 15%-20% among females and...
Employment as a Mental Health Peer Support Technician in the Veterans Health Administration

Jack Clark, CHQOER, EN Rogers Memorial Veterans Hospital; Susan Eisen, EN Rogers Memorial Veterans Hospital; Mark Schultz, CHQOER, EN Rogers Memorial Veterans Hospital; Bei-Hung Chang, COLMR, Boston VA Healthcare System; Lisa Mueller, VISN 1 MIRECC, EN Rogers Memorial Veterans Hospital; Patricia Sweeney, VISN 1 MIRECC, EN Rogers Memorial Veterans Hospital; Moe Armstrong, San Francisco VAMC; Sandra Resnick, VHA Office of Psychosocial Rehabilitation and Recovery

Presenter: Jack Clark, Ph.D., Medical Sociologist, CHQOER, EN Rogers Memorial Veterans Hospital, jaclark@bu.edu

Research Objective: The VHA, a major provider of mental health care in the US, is employing increasing numbers of Veterans with mental illness as peer support staff. However, the nature of their work and its effects on their own mental health are not well described. This is the first study to characterize the jobs (functions, responsibilities, limitations, satisfaction and burnout) and mental health recovery (self-efficacy, symptoms and functioning, stigma, and quality of life) of Veterans with histories of mental illness employed as peer support technicians in VA mental health programs. We also compared peer support technicians’ employment experiences and mental health recovery with that of Veterans recently hired as vocational rehabilitation specialists through the Homeless Veterans Supported Employment Program (HVSEP), who have histories of homelessness but are not identified as peer support staff.

Study Design: Eligible participants were invited to complete an online survey comprised of established measures of work limitations, job satisfaction, job burnout, self-efficacy, stigma, mental health symptoms and behavior, and quality of life.

Population Studied: All Veterans employed nationally by the VHA as peer support technicians (N=288) or HVSEP vocational rehabilitation specialists (N=378) at the time of the study were eligible. 157 peer support technicians (55%) and 230 vocational rehab specialists (61%) responded to the survey. Across the two cohorts, 25% were female, average age was 50, 45% were racial minorities (primarily African-American) and 7% were Latino.

Principal Findings: The most frequently reported job responsibilities of peer support technicians (noted by more than 75%) were leading groups, sharing recovery experiences, helping Veterans set goals, providing 1:1 mentoring, teaching social skills, serving as a role model, challenging negative self-talk, advocating for Veterans, attending staff meetings, participating in conference calls, entering notes into medical records and doing paperwork. Job responsibilities reported by more than 75% of vocational rehab specialists included helping Veterans find work, helping with job skills, attending staff meetings, participating in conference calls, and entering notes into medical records. Compared with vocational rehab specialists, peer support technicians reported receiving significantly less supervision, and had lower levels of satisfaction with respect to amount of supervision received, senior management at their facility, amount of pay, and opportunities for promotion. Among 16 quality of life areas, only work life showed a statistically significant difference with vocational
Validating a Brief Measure of Mental Health Recovery

Amy Cohen, Greater Los Angeles VA Healthcare Center; Nikki Armstrong, PhD, US Army Health Clinic, Schofield Barracks, HI; Gerhard Hellemann, PhD, University of California, Los Angeles (UCLA); Alexander S. Young, MD, MSHS, Greater Los Angeles VA Healthcare Center and UCLA

Presenter: Amy Cohen, Ph.D., Psychologist, Mental Illness Research, Education, and Clinical Center, Greater Los Angeles VA Healthcare Center, ancohen@ucla.edu

Research Objective: With the groundswell of attention on recovery and patient-centered care in specialty mental health, there have been efforts to transform care to reflect these principles. Efficient and standardized approaches to assess recovery are needed. Although promising instruments exist, most are burdensome and have multiple domains that have not been established as separate constructs. This paper evaluates the psychometric properties of the Mental Health Recovery Measure (MHRM) in a large sample of VA patients and suggests a shortened version, the MHRM-10.

Study Design: As the largest quality improvement study in VA specialty mental health, "Enhancing Quality of Care in Psychosis" provided an opportunity to collect recovery data. Baseline data from this trial involving eight medical centers contributed to this cross-sectional analysis. In addition to the MHRM, measures included demographics, psychiatric symptoms, functioning, quality of life, and satisfaction with care. Reliability and validity of the MHRM were examined through internal consistency, factor analysis, and Pearson correlation procedures.

Population Studied: 795 veterans with schizophrenia who were receiving outpatient mental health treatment enrolled.

Principal Findings: Despite eight conceptual domains suggested by MHRM authors, factor analysis suggested that a single factor solution was most appropriate as it explained 37% of the overall variance in the MHRM, with additional factors accounting for no more than 5% of the overall variance in the measure. Individual MHRM items loaded strongly on this single recovery factor, with all but three items having factor loadings above .400, a common cutoff for including an item in a factor score. The 10-items with the highest factor loadings were chosen to create the MHRM-10, as these items most strongly represented the underlying recovery construct. The factor loadings of the 10-items were all very high and of similar magnitude, ranging from .66-.79. Overall internal consistency for the MHRM-10 was good (Cronbach’s α = .91) and comparable to the full MHRM in our sample (Cronbach’s α = .94), as well as to reliability estimates observed in the MHRM test developers’ two non-Veteran samples (Cronbach’s α = .93 and .95). Pearson correlations between the MHRM-10 and measures of quality of life (r = .52, p < .01), satisfaction with care (r = .19, p < .01), depression symptom severity (r = -.40, p < .01), thought disturbance (r = -.17, p < .01), occupational functioning (r = .14, p < .01), social functioning (r = .08, p < .05), and symptom severity (r = .19, p < .01) were strikingly similar to correlations observed between the full MHRM and these same measures. Total mean score for the MHRM-10 was 27.6 (SD = 6.7; range = 0-40).

Conclusions: The MHRM is a reliable and valid measure that is best interpreted as a total score. A 10-item version of the MHRM maintained comparable psychometric properties, reducing measurement burden. Replication of findings in a different sample and establishing sensitivity to change over time is suggested.

Implications for Policy, Delivery, or Practice: As the VHA expands its initiative to hire 800 more peer support technicians, new strategies are being implemented to upgrade these positions, acknowledge their role in mental health care, and provide opportunities for promotion. These efforts will be important in eliminating disparities and enhancing mental health recovery outcomes.
Implications for Policy, Delivery, or Practice:
These data provide initial support for use of the MHRM-10 to measure recovery in this population. Using this efficient 10-item MHRM would allow for measurement of progress towards a recovery transformation.

Trends in Smoking and Tobacco Product Use among Individuals with Mental Illness in 2005-2010
Benjamin Cook, Harvard Medical School; Geoffrey Ferris Wayne, Center for Multicultural Mental Health Research; Zimin Liu, Center for Multicultural Mental Health Research

Presenter: Benjamin Cook, Ph.D., M.P.H., Assistant Professor and Senior Scientist, Center for Multicultural Mental Health Research, Harvard Medical School, bcook@chareresearch.org

Research Objective: Significant progress has been made in reducing the prevalence of tobacco use in the United States. However, individuals with mental illness demonstrate greater rates of tobacco use than the general population and comprise between 33% and 50% of remaining smokers. We examine whether declines in tobacco use in the general population have also been realized among individuals with mental illness, assess whether those with and without mental illness differ with regard to product type preferences (e.g. high nicotine, menthol, lower perceived risk) and measure whether these differences vary by race/ethnicity.

Study Design: Analysis of multiple cross-sectional datasets to assess trends in smoking rates and product preferences among individuals with and without mental illness. We estimate unadjusted rates of tobacco use, dependence and product preference by time, mental illness and race/ethnicity. Multivariate regression models using two-way and three-way interactions assess the associations of mental illness and race/ethnicity on trends in tobacco use, adjusting for socioeconomic and health status covariates.

Population Studied: We use six years (2005-2010) of data from the National Survey on Drug Use and Health (NSDUH). We analyze data from individuals with and without mental illness. Mental illness is operationalized as having sufficient depressive symptoms to be likely to have a diagnosis of major depressive episode (MDE) or as having severe psychological distress (SPD) according to the Kessler-6 survey of psychological distress.

Principal Findings: Individuals diagnosed with major depressive episode (MDE) or as having severe psychological distress (SPD) increased their rates of nicotine dependence and use of full flavor cigarettes between 2005 and 2010 while the corresponding trends decreased among those without these conditions. Analyses by race/ethnicity of individuals with MDE or SPD demonstrate substantial increases between 2005 and 2010 in full flavor, high nicotine cigarette use among Asians (2.5% to 9.4%) and Latinos (10.8% to 14.7%) whereas white levels remained relatively steady (15.6% to 16.7%) and Black levels decreased but remained troublingly high (26.9% to 23.8%).

Conclusions: A growing proportion of current smokers have mental illness and racial/ethnic minorities with mental illness may be particularly vulnerable to increased harm from tobacco use.

Implications for Policy, Delivery, or Practice: Results suggest that FDA and other regulatory agencies, and public health departments should increase their efforts to decrease the rates of smoking among individuals with mental illness. Interventions focused on reducing smoking rates among racial/ethnic minorities with mental illness should also be a priority.

Prevalence of Suicidality among Hispanic and African-American Veterans Following Surgery
Laurel Copeland, Scott & White Healthcare; Central Texas Veterans Health Care System; Raphael T McIntyre, Scott & White Healthcare; Eileen M Stock, Scott & White Healthcare; John E Zeber, Center for Applied Health Research, Central Texas Veterans Health Care System; Scott & White Healthcare; Daniel J MacCarthy, South Texas Veterans Health Care System; Mary Jo V Pugh, South Texas Veterans Health Care System

Presenter: Laurel Copeland, Ph.D., Associate Director, Center for Applied Health Research, Scott & White Healthcare; Central Texas Veterans Health Care System, laurelacopeland@gmail.com

Research Objective: The Veterans Health Administration [VA] prioritizes suicide prevention
as a critical focus. Historically, suicidal behavior and ideation [SBI] among Latinos and African Americans has received little attention because of their low suicide rates. Minority veterans may be an exception. VA patients undergoing major surgery exhibit many risk factors for SBI, including being highly disabled with multiple physical and mental disorders; in addition, many are of minority race. Although few individuals express SBI, these actions and thoughts are potent predictors of suicide. Therefore, this study evaluated factors including race and ethnicity associated with postoperative SBI among VA surgery patients.

**Study Design:** Extracts from VA’s electronic medical records were analyzed in the retrospective cohort study. SBI was ascertained by ICD-9 diagnosis and E-codes for suicidal ideation and suicidal behavior, respectively, during the three years following surgery. Postoperative risk of SBI associated with race and ethnicity was estimated via Cox proportional hazards model adjusting for clinical and demographic covariates.

**Population Studied:** The study examined 89,995 VA patients undergoing major surgery October 2005-September 2006 as part of the Surgical Treatment Outcomes for Patients with Psychiatric Disorders [STOPP] study of surgery experiences among veterans with severe mental illness.

**Principal Findings:** African-Americans [16,252; 18 percent] were at increased risk of SBI [HR=1.2; 95% CI 1.1-1.3] while Hispanics were not [HR=1.1; 95% CI 0.95-1.3]. Other risk factors included schizophrenia, bipolar disorder, depression, post-traumatic stress disorder, pain disorders, postoperative new-onset depression, and postoperative complications, while female gender and married status were protective.

**Conclusions:** The postoperative period may be a time of heightened risk for SBI amongst minority patients in the VA. Research into postoperative coping and recovery is needed. Tailored monitoring and post-operative management by minority status may be required to achieve care equity. In terms of mechanism, suicidal behavior and ideation represent untreated mental anguish, especially depression, which may lead to decreased healing and increased new-onset disease after surgery. In other research, minority patients have reported more severe pain and pain-related interference with physical function than their white counterparts, and been more likely to be prescribed medication that was inadequate for their pain intensity after a major surgery.

**Implications for Policy, Delivery, or Practice:** Providers must be cognizant of not only physical pain or other postoperative symptoms but also new or exacerbated mental distress. Postoperative recovery is a process which can be problematic, marked by pain and disability, and for some, suicidal ideation occurs in the process of seeking a solution to the problem. Patient activation interventions may need to be tailored for cultural sub-groups to enable minority patients to better cope with the perioperative period. Effective clinical care for mental, physical, and substance disorders is critical to protect against suicidal behavior and ideation, especially at times of stress which may include major health care events. Differences in post-operative coping by race and ethnicity should be assessed in future research to spur development of tailored postoperative care plans that take into account variation in ability to cope with pain and recovery.

**Results from a Developmental Formative Evaluation of the Monitoring and Management of Metabolic Side Effects of Antipsychotic Medications in 12 VA Medical Centers**

**Presenter:** Karen Drummond, Ph.D., Research Health Scientist, HSR&D, Central Arkansas Veterans Healthcare System, karen.drummond@va.gov

**Research Objective:** Second-generation antipsychotics (SGAs) are prescribed to over 80% of veterans with psychotic disorders. Unfortunately, treatment with many SGAs is associated with metabolic side effects such as overweight/obesity, diabetes, and hyperlipidemia. Evidence-based and consensus-based recommendations for monitoring and management of these effects are contained in VA clinical practice guidelines for psychoses, obesity, diabetes, and dyslipidemia. However,
research has found low rates of metabolic monitoring and significant delays in management of metabolic abnormalities among patients treated with antipsychotics. The overall objective of the current study is to test an implementation intervention (an Evidence-Based Quality Improvement / Facilitation [EBQI/F] intervention) to enhance uptake of evidence-based tools and strategies to improve monitoring and management of metabolic side effects of antipsychotics, within the context of a national implementation effort within the VA.

**Study Design:** The study employs a quasi-experimental, multiple case-study design to test the EBQI/F intervention combined with the national implementation strategy, compared to the national implementation strategy alone. The study is being conducted at 12 VA Medical Centers (VAMCs), with six VAMCs assigned to receive the intervention and six assigned to the control group (national implementation strategy only). We are using multi-phase formative evaluation methods to support development of local implementation strategies, document and evaluate the process and success of the EBQI/F intervention, identify barriers/facilitators, and identify potential refinements to the intervention for future implementation efforts. For summative evaluation, we will employ time series analyses to assess intervention effects on performance of guideline-recommended metabolic monitoring and management during pre-implementation, implementation, and post-implementation study periods. This paper reports results of the recently completed first phase of the developmental formative evaluation.

**Population Studied:** The developmental formative evaluation process began with pre-implementation interviews with providers and other clinical staff involved in prescribing antipsychotics and/or the monitoring and management of the metabolic side effects of the medications.

**Principal Findings:** We conducted over 90 pre-implementation interviews with VA mental health providers and other relevant mental health staff members at all twelve participating VA medical centers for the first phase of the developmental formative evaluation. Our analysis of the interview data reveals that critical barriers to guideline-concordant monitoring and management of metabolic side effects of antipsychotic medications exist within the participating VAMCs. Our findings indicate that significant barriers are present at the system, staff, and patient levels.

**Conclusions:** To plan for effective interventions, it is important to understand the current barriers to guideline-concordant monitoring and management and to distinguish between site-specific versus common barriers. While some of the reported barriers are site specific, others were found across multiple VAMCs and may thus be generalizable and of interest beyond the VA.

**Implications for Policy, Delivery, or Practice:** Our study addresses an important patient safety concern for patients taking antipsychotic medications, specifically the need for timely monitoring and management of metabolic side effects of antipsychotics. Quality improvement (QI) in this area could help prevent or reduce morbidity associated with overweight/obesity, diabetes, and hyperlipidemia for these patients. To plan for effective QI it is important to understand the current barriers to guideline-concordant monitoring and management and to distinguish between site-specific versus common barriers.

**Harms of Prostate and Colorectal Cancer Screening Identified by Clinicians**

Emily A. Elstad, University of North Carolina at Chapel Hill; Emily Elstad, University of North Carolina at Chapel Hill; Maihan Vu, DrPH, MPH, University of North Carolina at Chapel Hill; Anne Sutkowski-Hemstreet, MPH, University of North Carolina at Chapel Hill; Stacey L. Sheridan, MD, MPH, University of North Carolina at Chapel Hill; Carmen L. Lewis, MD, University of North Carolina at Chapel Hill; Russel Harris, MD, MPH, University of North Carolina at Chapel Hill; Noel T. Brewer, PhD, University of North Carolina at Chapel Hill

**Presenter:** Emily Elstad, MPH, Student, Health Behavior, University of North Carolina at Chapel Hill, elstad@live.unc.edu

**Research Objective:** While many studies have focused on the potential benefits of screening tests, fewer have considered the potential harms. "Harms" are defined as any bad effects that may come from screening for and treating a disease once it is found. Screening for colorectal cancer with colonoscopy can lead to harm by problems from the preparation or the procedure as well as psychological distress. Screening for prostate cancer with the prostate-specific antigen (PSA) test can lead to harm by problems
from biopsy or treatment as well as psychological distress. Our study assessed the harms clinicians cite for prostate and colorectal cancer screening.

**Study Design:** A cross-sectional sample of clinicians completed a paper-based questionnaire. Clinicians were asked to list the harms of PSA testing for a 70-year old man with no family history of prostate cancer and no abnormal PSA tests, and colonoscopy for a 70-year old man with no family history of colon cancer or history of polyps. We categorized harms, used a paired t-test to compare the mean number of harms clinicians mentioned for each screening test, and McNemar’s ?2 test to compare the frequencies of harms cited for the two screening tests.

**Population Studied:** 112 of 158 (71%) of clinicians from 24 family/internal medicine practices in a North Carolina practice-based research network completed the survey. The clinicians were primarily physicians (80% MD/DO), 60% of whom were male and 77% white. Mean age was 45±9.7 (range 29-69) and mean years in practice was 15±9.3 (range 1-40).

**Principal Findings:** Overall, clinicians listed more harms for the PSA test than for colonoscopy (3.01 vs. 2.68, p=.02). Harms that clinicians listed more frequently for PSA than colonoscopy included harms related to: false positive test results/unnecessary follow-up testing (61% vs. 12%, p<.001)and follow-up tests/procedures (30% vs. 5%, p<.001). They also mentioned harms of: treatment, true positives with unclear benefit, and psychological sequelae more frequently for PSA. In contrast, the most frequently cited harms of colonoscopy were harms of the test itself (including prep for the test and sedation) (91% vs. 0% for PSA). Clinicians listed time/inconvenience more often as a harm of colonoscopy (18% vs. 7%, p=.003).

**Conclusions:** Findings support the perception of a “screening cascade” (whereby testing begets further potentially harmful testing, procedures and treatment with unknown benefit) of harms for PSA but not for colonoscopy. For example, clinicians more often cited false positive tests, unnecessary testing/procedures and their harms, and unclear benefits of true positive tests as harms of PSA testing. In contrast, clinicians cited more immediate test-related harms for colonoscopy, omitting other potential harms. Interestingly, PSA screening rates remain high despite current clinical guidelines and apparent acknowledgement of screening harms found in this study.

**Implications for Policy, Delivery, or Practice:** These findings augment our understanding of how clinicians perceive cancer screening harms and are important given nascent research on screening harms relative to its benefits. Our findings can inform future research to reduce harms and improve patient care.

**Population Health Approaches and Alternative Strategies for Children’s Mental Health Care in Wisconsin**

Elizabeth Feder, University of Wisconsin; Kara Mandell, University of Wisconsin; Angela Forgues, University of Wisconsin; Iliya Amaza, University of Wisconsin

**Presenter:** Elizabeth Feder, Ph.D., Associate Researcher, Population Health Institute, University of Wisconsin, efeder@wisc.edu

**Research Objective:** To identify innovative population health approaches and alternative children’s mental health care strategies at the community level that may reduce the need for the use of anti-psychotic pharmaceuticals among high risk children.

**Study Design:** This qualitative study used surveys and semi-structured interviews with stakeholders and prescribers to identify novel, population-based strategies to address children's mental health in Wisconsin. Practitioners and stakeholders were identified using a snowball method.

**Population Studied:** Data was abstracted from 41 semi-structured interviews with Wisconsin thought-leaders from a variety of prescribing communities including child psychiatry, psychiatry, family medicine, pediatrics and advance practice nursing. Data was also collected from 21 other stakeholders including executive directors of advocacy and professional organizations, directors of private child and family mental health and social service agencies, leadership of county mental health and human service departments and school of pharmacy faculty.

**Principal Findings:** Stakeholders reported that much of the antipsychotic use in Wisconsin might be preventable through early intervention and/or coordination of other services. The impact of early childhood trauma and disrupted attachment in highly stressed families was cited as an important factor in the emotional and behavioral difficulty of many children, especially
those in the foster care system. The stresses of poverty overall was also identified as a significant contributor to mental health issues. Several Wisconsin communities are engaged in population based non-pharmaceutical prevention and treatment strategies to address risk factors for antipsychotic use. At the prevention level, Richie Davidson has brought regular meditation practice for students at at-risk schools in Madison. The La Causa School in Milwaukee has implemented a treatment intervention, “Nuestros Ninos, Nuestro Futuro” for students in grades 5-8 who have experienced trauma or PTSD. The program uses group-based cognitive-behavioral therapy (CBT) to address the consequences of community violence. Conclusions: Early intervention and family support services are frequently cited as potential avenues to reduce antipsychotic use. Additionally, school-based, population interventions may also show promise in reducing rates of powerful medications among children. Several exemplary programs focused on population mental health have been implemented at the community level in Wisconsin. Implications for Policy, Delivery, or Practice: The rate of antipsychotic use among children has grown enormously in Wisconsin and the nation in recent years. Antipsychotics may not be cost-effective compared with early intervention and have significant side effects that may last much longer than treatment. Wisconsin, like other states, faces a shortage of child psychiatrists, and looking to upstream and population-based approaches may make sense. Many children who are at risk to be treated with antipsychotics may respond to population level interventions. This study identifies several promising practices that have been implemented in communities in Wisconsin. Such population level interventions may help to decrease disparities in prescribing and improve the health of the children of Wisconsin. Funding Source(s): Other, Wisconsin Department of Health Services Poster Session and Number: B, #571

Geographic and Demographic Disparities in the Prescription of Antipsychotic Drugs among Children in Wisconsin
Elizabeth Feder, University of Wisconsin; Kara Mandell, University of Wisconsin; Kristen Voskuil, University of Wisconsin

Presenter: Elizabeth Feder, Ph.D., Associate Researcher, Population Health Institute, University of Wisconsin, efeder@wisc.edu

Research Objective: To identify geographic and demographic disparities in the use of antipsychotic drugs among children in foster care or who receive Medicaid in Wisconsin. Study Design: This study used data from Wisconsin Medicaid claims for children ages 0 to 18 between 2008 and 2011 including county of residence. We identified children who received at least one fill of an antipsychotic prescription using National Drug Codes (NDCs) from the study time period. We used National Provider Index (NPI) numbers to identify provider self-reported specialty. Finally, we used data from the County Health Rankings to identify county-level characteristics including demographic and economic data, disease prevalence rates (including diabetes and mental illness), and access to quality health care (based on the rate of preventable hospital stays, diabetic screening and mammography screening from the Dartmouth Atlas). To identify disparities in prescribing practices, this study used non-linear hierarchical linear modeling and GIS mapping. Quantitative data was augmented by interview data with prescribers treating children in high poverty areas. Population Studied: Children ages 0 to 18 in Wisconsin who were insured by Medicaid including those who were in foster care between 2008 and 2011 (n=439,567), including 13,187 children who received at least one antipsychotic fill. Principal Findings: GIS mapping shows that disparities exist in the number of children who were prescribed antipsychotics by geographic area. Children in foster care were more likely to be medicated, to be medicated for longer, and to experience polypharmacy than other children who receive Medicaid. We do not find disparities in antipsychotic prescriptions by provider type. Using hierarchical linear modeling, we found that children living in counties with higher median income are less likely to receive antipsychotics such that for every thousand dollar increase in median income, the probability of a child receiving an antipsychotic is reduced by five percent (OR=.95, 95% CI: .92-.97). In addition, children living in counties where the population is uninsured are less likely to receive antipsychotics (OR=.84, 95% CI: .72-.98). We did not find relationships between quality of
Community providers. The study will identify perspectives of communities where Veterans live from the need for suicide prevention services in the local overall objective of the study is to examine the underutilization of VA services among Veterans, as well as other Veterans not enrolled in VA care is of great concern. The overall objective of the study is to examine the need for suicide prevention services in the local communities where Veterans live from the perspective of a diverse group of VA and community providers. The study will identify provider and organizational barriers to care with a focus on those unique to Veterans living in rural areas that are at risk for suicide.

**Study Design:** This study used a mixed methods design including both semi-structured interviews and a quantitative survey. Interview questions focused on the perception of Veteran’s needs for VA and/or community-based services and more specifically, suicide prevention services, as well as referral mechanisms to address service needs and potential barriers to receiving services. Survey questions assessed participant demographics, including information about the organization, participant veteran status, and experience with suicide.

**Population Studied:** This study recruited and gathered survey and interview data from a diverse group of stakeholders (N=70) that represent key VA and non-VA community-based agencies that provide a range of health and psychosocial services to veteran and/or military populations living in the state of Missouri.

**Principal Findings:** Preliminary analyses of the survey data indicate that the majority of our participants were white, male, and educated, with less than 15 years of clinical / medical experience. Broad themes from a preliminary qualitative analysis suggest that both community and VA providers perceive a need for increased services, both generalized and suicide prevention-specific. Generalized needs include financial support, transportation, mental health care and increased support during a Veteran’s transition from the military back to civilian life. Suicide prevention services should be tailored to reach each generation of Veterans where they are most comfortable.

**Conclusions:** More can be done by the VA system to improve connections with community providers in several different service sectors. A variety of platforms for communication, including targeted interventions for providers, public service announcements, and smart phone apps, are discussed. These results will inform a future research on the design and feasibility testing of an innovative organizational barrier-breaking intervention study. These results will help create an infrastructure for suicide prevention that is in line with national strategies for suicide prevention, including sustaining and strengthening collaboration among agencies, and reduce barriers to access to suicide prevention services.

**Implications for Policy, Delivery, or Practice:** Clinically, we know that enrolled and non-

**Stakeholder Perspectives on Improving Access to VHA’s Suicide Prevention Services**

Monica Matthieu, PhD, St. Louis VA Health Care System; Gianni Gardiner, Washington University; Ellen Zeigemeier, Washington University; Miranda Buxton, Washington University; Lu Han, Washington University

**Presenter:** Gianni Gardiner, M.S.W., Research Project Coordinator, Social Work, Washington University, ggardiner@gwbmail.wustl.edu

**Research Objective:** Veterans using VA health care services are at heightened risk for death by suicide. Epidemiological data on previous combat Veteran cohorts and data on underutilization of VA services among Veterans suggest that suicide risk among our newest cohort of Veterans, as well as other Veterans not enrolled in VA care is of great concern. The overall objective of the study is to examine the need for suicide prevention services in the local communities where Veterans live from the perspective of a diverse group of VA and community providers. The study will identify provider and organizational barriers to care with a focus on those unique to Veterans living in rural areas that are at risk for suicide.

**Study Design:** This study used a mixed methods design including both semi-structured interviews and a quantitative survey. Interview questions focused on the perception of Veteran’s needs for VA and/or community-based services and more specifically, suicide prevention services, as well as referral mechanisms to address service needs and potential barriers to receiving services. Survey questions assessed participant demographics, including information about the organization, participant veteran status, and experience with suicide.

**Population Studied:** This study recruited and gathered survey and interview data from a diverse group of stakeholders (N=70) that represent key VA and non-VA community-based agencies that provide a range of health and psychosocial services to veteran and/or military populations living in the state of Missouri.

**Principal Findings:** Preliminary analyses of the survey data indicate that the majority of our participants were white, male, and educated, with less than 15 years of clinical / medical experience. Broad themes from a preliminary qualitative analysis suggest that both community and VA providers perceive a need for increased services, both generalized and suicide prevention-specific. Generalized needs include financial support, transportation, mental health care and increased support during a Veteran’s transition from the military back to civilian life. Suicide prevention services should be tailored to reach each generation of Veterans where they are most comfortable.

**Conclusions:** More can be done by the VA system to improve connections with community providers in several different service sectors. A variety of platforms for communication, including targeted interventions for providers, public service announcements, and smart phone apps, are discussed. These results will inform a future research on the design and feasibility testing of an innovative organizational barrier-breaking intervention study. These results will help create an infrastructure for suicide prevention that is in line with national strategies for suicide prevention, including sustaining and strengthening collaboration among agencies, and reduce barriers to access to suicide prevention services.

**Implications for Policy, Delivery, or Practice:** Clinically, we know that enrolled and non-
enrolled Veterans are often engaged in community-based services in addition to VA care; therefore, a community-based intervention designed by the stakeholders who work with our Veterans is much needed. By examining the interaction between stakeholder groups and pathways to VA care, this intervention will also provide Suicide Prevention Coordinators (SPCs) with information on which community agencies are most in need of VA outreach and services.

**Working with a Severe Mental Illness: Stressful or Salubrious for Overall Mental Health?**

Brent Gibbons, University of Maryland, Baltimore County

**Presenter:** Brent Gibbons, M.P.P., Phd Student, Public Policy, University of Maryland, Baltimore County, sephjoe@gmail.com

**Research Objective:** State provision of vocational rehabilitation services for those with a severe and persistent mental illness (SMI) depends in part on state resources and a state’s inclination to provide such support services. Clearer answers as to how employment affects both the clinical status and use of mental health services by those with a SMI will help states determine if and how such vocational services should be offered. Results may also inform the psychiatric treatment community of the significance (if any) that working has in one’s overall treatment and recovery process.

Evidence suggests employment may improve symptoms and reduce mental health service use (e.g. # of hospitalizations). However, this evidence comes from project-specific evaluation data that 1) fails to control for endogeneity of employment status and 2) may not generalize to broader populations. This study examines the effect that working has on two outcome variables, mental health status and total mental health costs, for all individuals in the study, and separately for individuals eligible through the Federal program Supplemental Security Income (SSI).

**Study Design:** The two primary data sources are 1) the Outcomes Measurement Survey (OMS) for those using Maryland’s PMHS and 2) Maryland PMHS claims data for the same persons and time period. The design is quasi-experimental, with a “treatment” group (n=1,033) and a comparison group (n=5,733) defined by work status (currently working or not) in the 2nd of 3 consecutive OMS interviews over a one-year period. Mental health status is measured by a 24-question instrument that produces an overall score that is not diagnosis specific. Total mental health costs are calculated from claims records from the 6-month period between the 2nd and 3rd interviews. A full information maximum likelihood (FIML) estimation simultaneously models the potentially endogenous variable work status and the outcome variable. FIML allows a probit estimation for the binary dependent variable work status. A test of endogeneity is also feasible under FIML, which if insignificant suggests corrections for endogeneity are unnecessary and OLS regressions are performed instead.

**Population Studied:** The population is those with a SMI, covered through Maryland’s Public Mental Health System (PMHS) between September 2006 and August 2009.

**Principal Findings:** Results are mixed, with mental health status not showing improvement, but total mental health costs being significantly decreased for those who worked. Some differences in results are observed between SSI eligibles and other study subjects. Tests of endogeneity tend to be significant for work status with mental health status as the outcome of interest, but insignificant for the outcome of total mental health costs. An interaction term between the quantitative variable prior mental health status and work status exposes a treatment effect for the outcome mental health status that increases for those with poorer prior mental health status.

**Conclusions:** Please see principal findings and Implications.

**Implications for Policy, Delivery, or Practice:** Implications are that vocational programs may have cost offsets in the form of lowered mental health costs for non-SSI eligibles, but not for SSI eligibles.

**Funding Source(s):** No Funding

**New Behavioral Health Issues Identified by Screening in Masshealth Children**

Karen Hacker, Institute for Community Health, Cambridge Health Alliance and Harvard Medical School; Robert Penfold, Ph.D, GroupHealth Research Institute; Lisa Arsenault, Ph.D., Institute for Community Health, Cambridge Health Alliance; Fang Zhang, Ph.D, Department of Population Medicine, Harvard Medical School,
positive modifiers. They were more likely to be all children and 9.7% of screened children had 46% had evidence of screening. Four percent of children with screens and modifiers. Multivariate logistic regression was used to determine predictors of positive screens among children with screens and modifiers (123,385) included, gender (male), age (older), foster care, BH history, and Hispanic ethnicity.

Of the children with a positive modifier, almost half (43%) had no BH history. Compared to those with prior BH history, they were more likely to be female, younger, minority, and from rural residences (P <.0001).

Conclusions: The high rate of newly identified Medicaid children with a BH need suggests that screening is performing well, especially since these children tended to be from historically underidentified groups. Future work is needed to determine whether identification leads to subsequent outpatient mental health treatment in order to better assess screening value.

Implications for Policy, Delivery, or Practice: For states considering mandated behavioral health screening, it is important to note that a majority of identified children may have prior behavioral health history. Screening in primary care may facilitate better integration with mental health. To better assess screening value for newly identified children, it will be important to follow their future service trajectories and determine whether early identification improves health and health service outcomes.

Funding Source(s): NIH

Presenter: Karen Hacker, M.D., M.P.H., Executive Director, Institute for Community Health, Cambridge Health Alliance and Harvard Medical School, khacker@challiance.org

Research Objective: To identify predictors of positive screening modifiers in Massachusetts Medicaid children who received mandated behavioral health (BH) screening.

Study Design: Mandated BH screening began in Massachusetts as part of the Rosie D. vs. Patrick remedy (12/2007). Providers were asked to use a screening CPT code and subsequently a modifier to indicate whether a BH need was identified. MassHealth claims data from before and after the mandate was obtained. Children with at least 300 days of eligibility in Fiscal Year (FY) ’09 (6/08 - 7/09) were identified and categorized into 5 groups based on the first use of the modifier, screening code or claim (salient visit)-children with: (1) screens and negative modifiers, (2) screens and positive modifiers, (3) screens without modifiers, (4) well-child visits without documented screens, and (5) children without well-child visits or screens. Bivariate analyses were conducted to determine differences among groups. Then to examine BH history, continuously enrolled children in FY’08 and ’09 were identified. BH history was defined as any claim prior to the salient screening visit with a mental health diagnosis (ICD9 290-319), a mental health CPT code, or for psychopharmacology. Children with positive modifiers were examined by BH history. Multivariate logistic regression was used to determine predictors of positive screens among children with screens and modifiers.

Population Studied: The population studied included children under 16 with at least 300 days of eligibility in MassHealth and utilization in FY’09.

Principal Findings: There were 355,490 children who met study criteria in FY’09 of whom 46% had evidence of screening. Four percent of all children and 9.7% of screened children had positive modifiers. They were more likely to be male, older and in foster care compared to all others (P <.0001). Of the 316,698 children who met criteria for BH history, 28% had an existing BH history. Of those screened (153,760), 27% had a BH history. Factors that predicted a positive modifier among children with screens and modifiers (123,385) included, gender (male), age (older), foster care, BH history, and Hispanic ethnicity.

Of the children with a positive modifier, almost half (43%) had no BH history. Compared to those with prior BH history, they were more likely to be female, younger, minority, and from rural residences (P <.0001).

Implementation-Focused Process Evaluation of an Incentive Intervention for Substance Use Disorders Treatment

Hildi Hagedorn, VA Substance Use Disorders QUERI, Minneapolis VA Healthcare System; University of Minnesota School of Medicine; Cheryl Stetler, Health Services Department, Boston University School of Health; Ann Bangerter, Center for Chronic Disease Outcomes Research, Minneapolis VA Healthcare System; Saimak Noorbaloochi, Center for Chronic Disease Outcomes Research, Minneapolis VA Healthcare System; Maxine Stitzer, Johns Hopkins University School of Medicine; Daniel Kivlahan, Center of Excellence in Substance Abuse Treatment and Education, VA Puget Sound Healthcare System; University of Washington School of Medicine
Presenter: Hildi Hagedorn, Ph.D., Staff Psychologist, Psychiatry, VA Substance Use Disorders QUERI, Minneapolis VA Healthcare System; University of Minnesota School of Medicine, hildi.hagedorn@va.gov

Research Objective: A pressing concern in healthcare today is the slow rate at which promising interventions move into clinical practice. Hybrid study designs, combining collection of effectiveness and implementation-related data, are one method to speed this process. This hybrid trial tested the effectiveness of an incentive intervention for substance use disorders (SUD) treatment while simultaneously collecting implementation-focused process evaluation data. The goals of this paper are to provide an example of a Hybrid Type I design, to demonstrate the value of theory in developing process evaluation questions/summarizing results and to provide practical guidance for implementation of incentive interventions in SUD clinics.

Study Design: The process evaluation design was informed by the RE-AIM and PARIHS implementation frameworks. Elements from the frameworks guided the development of specific process evaluation questions. Data tools used included the Organizational Readiness to Change Assessment (ORCA), patient surveys, staff and leadership interviews, observational notes, and chart reviews. Information from the different data tools were triangulated to reach conclusions related to each of the implementation framework elements.

Population Studied: The study was conducted in three Veterans Health Administration SUD treatment clinics. Patients were eligible if they were beginning a new treatment episode for alcohol and/or stimulant dependence. One-hundred forty-seven patients completed post-intervention surveys. All clinical staff were eligible to participate. Twenty-six staff completed the ORCA while nine staff and all clinic leaders completed interviews.

Principal Findings: Reach: Sixty percent of patients approached agreed to participate in the intervention. Most declined because the intervention appointments were too frequent. Adoption: Clinic leaders’ perceptions that incentive interventions were evidence-based, strongly supported by national leadership, and improved patients’ program retention were all incentives to adopt the intervention. However, these incentives could not overcome the barriers of lack of funding and staff time to carry out, i.e., implement, the intervention. Clinic leaders reported that facility leadership support in the form of additional funds or staff time would be required for adoption. Implementation: Clinic staff and leadership indicated that high-fidelity implementation would require expert consultation, involving all staff in implementation planning, and clearly defining staff roles in regards to the intervention. Maintenance: Clinical staff and leadership indicated that starting the intervention in only one treatment track would cut down on initial staff and funding requirements, increase staff familiarity and skill with the intervention, and allow for demonstration of intervention impact, all of which would support spread and maintenance of the intervention in other treatment tracks. Evidence: Staff at all clinics generally agreed with the evidence supporting the intervention but indicated their clinics lacked necessary resources. Context: Staff at the involved clinics reported a leadership and staff culture supportive of innovation.

Conclusions: This Hybrid Type I trial expanded the value of the effectiveness trial by concurrently collecting data that provided valuable insights into the design of future implementation efforts.

Implications for Policy, Delivery, or Practice: Research funders should encourage hybrid study designs to increase the rate at which innovative clinical interventions move to the implementation phase of the research pipeline.

Implementation of Consumer Providers in Mental Health Settings

Alison Hamilton, VA Greater Los Angeles; Matthew Chinman, PhD, VA Pittsburgh Healthcare System & RAND; Amy N. Cohen, PhD, VA Greater Los Angeles Healthcare System & UCLA; Rebecca Shoai Oberman, MSW, MPH, VA Greater Los Angeles Healthcare System; Alexander S. Young, MD, MSHS, VA Greater Los Angeles Healthcare System & UCLA

Presenter: Alison Hamilton, Ph.D., M.P.H., Research Health Scientist, Desert Pacific MIRECC, VA Greater Los Angeles, alison.hamilton@va.gov

Research Objective: Consumer providers (CPs) are individuals with a serious mental illness (SMI) who draw upon their lived
experiences of a mental health disorder to provide services to others with a SMI. Utilizing CPs is considered an innovative clinical approach that can support usual services in a number of ways: they can facilitate the learning of self-management skills, provide hope, engage clients into treatment, serve as role models, and help clients connect with others in their communities. There is growing evidence for the effectiveness of CPs in national and international mental health settings. However, those who have conducted studies of CPs have consistently noted challenges related to implementation of this role, including boundary issues, confidentiality, disclosure of disability status, discrimination, and poorly defined job structure. The objective of this study is to describe facilitators and challenges to implementation of CPs in mental health treatment settings.

**Study Design:** The PEER project (Peers Enhancing Recovery) is the first study to use a systematic approach to implementation of CPs. The project was a one-year cluster randomized controlled trial comparing three mental health intensive case management (MHICM) teams that incorporated CPs compared to three other MHICM teams that continued without CPs. An evaluation of CP implementation was conducted involving semi-structured interviews and focus groups.

**Population Studied:** At intervention sites, consumer providers (n=5), other providers (n=8), and clients (n=10), as well as members of the research team (n=4).

**Principal Findings:** Site preparation, external facilitation, and positive, reinforcing experiences with CPs facilitated implementation. Non-CP staff, particularly MHICM administrators, appreciated having consistent access to expertise and resources, as well as being able to troubleshoot issues with the research team. External facilitation was particularly important when staff within sites were having conflicts. CPs also appreciated access to the research team, and benefited from weekly phone or in-person supervision. All staff conveyed that the CPs were a valuable addition to their teams, particularly when the CPs’ strengths and competencies had been identified and demonstrated. CPs themselves were also able to observe their own contributions, and this reinforced their sense of value on the teams and supported implementation; clients also recognized the value of CPs as role models and empathetic listeners. Role definitions and deficiencies in CPs’ technical knowledge posed challenges to implementation. Although there was widespread support behind maintaining the CP role at the sites, sustainability was not realized due to insufficient resources.

**Conclusions:** Implementation was positive overall, characterized by Diffusion of Innovation concepts of high relative advantage, strong trialability, compatibility with prevailing norms, compelling observability, and relatively low complexity. By preparing and working systematically with intervention sites to incorporate new services, implementation was strengthened and challenges were minimized.

**Implications for Policy, Delivery, or Practice:** Many healthcare organizations are hiring CPs and attention should be paid to implementation issues. External facilitation, ideally guided by an implementation framework, could be an important component of implementation, as are careful planning and anticipation of commonly experienced challenges. Increasing evidence of successful implementation could contribute to eventual sustainability of this effective addition to behavioral health services.

**The Relationship between Adverse Childhood Experiences and Truancy**

Nancy Hardt, University of Florida College of Medicine; Nathan Epps, Florida Department of Juvenile Justice; Kimberley Panther, University of Connecticut; David Wilding, University of Florida; Jeffrey Roth PhD, University of Florida

**Presenter:** Nancy Hardt, M.D., Senior Associate Dean, Pathology, University of Florida College of Medicine, hardt@ufl.edu

**Research Objective:** Background: Florida is unique in that in every judicial district, juveniles complete the same survey upon entry to the juvenile justice system to estimate their risk of reoffending. Among the survey questions asked are whether children have experienced adverse or traumatic events, and whether they have missed school. Adverse childhood experiences (ACEs) as described by Felitti and Anda categorize child maltreatment into abuse, neglect, and family dysfunction. The major predictor of involvement in juvenile justice or delinquency is truancy. The study assesses the relationship between ACEs and truancy among juvenile offenders in Florida.
**Study Design:** Method: The Florida Department of Juvenile Justice (FDJJ) uses a 126-item survey, the Positive Achievement Change Tool, to estimate the likelihood of re-offense among juvenile offenders. Responses on the PACT were coded as indicative of the presence of an ACE in 71,253 children under 18 interviewed between 2005 and 2010. Twenty-nine percent of children were truant. Logistic regression was used to calculate the odds of truancy as a function of number of ACEs.

**Population Studied:** 71,253 children in the Florida Juvenile Justice system.

**Principal Findings:** Results: Only 1.2% of children reported no adverse childhood experiences compared to 36% of the Kaiser Permanente insured reported by Felitti and Anda. Eighty percent of juvenile respondents were male; 62% were minority, and 29% were truant. Domestic violence and parental divorce were the most prevalent ACEs among truant offenders (80% and 78% respectively). Females were more likely to report all 10 ACEs than males and were six times more likely to report sexual abuse than males. Males were more likely to be truant than females. Truant males were 3 times more likely to report domestic violence than non-truant males. In the entire sample of offenders, 37% had 4 or more ACEs and the greater the number of ACEs, the higher the odds of truancy.

**Conclusions:** Conclusion: There is a direct proportional relationship between ACEs sum and truancy. Family dysfunction is the main association observed between ACEs and truant behavior in juvenile offenders. Few policies address prevention of adverse childhood experiences, rather most policies address secondary prevention. The signs of truancy begin as early as kindergarten. Policies for youth need to address youth attendance in school before children get involved in the juvenile justice system. Because the most common adverse experience reported by delinquent children with truancy is domestic violence, additional measures are needed to prevent children’s exposure to domestic violence. To begin, educating the public, especially pregnant women and parents of infants, that exposure to domestic violence can have far reaching consequences. These include reducing the likelihood of educational success and increasing the likelihood of involvement in the juvenile justice system.

**Implications for Policy, Delivery, or Practice:**

**Association of EMR Use with Anxiety Treatment During Office Visits in the United States**

Jeffrey Harman, University of Florida; Robert L. Cook, MD, University of Florida; Christopher A. Harle, PhD, University of Florida

**Presenter:** Jeffrey Harman, Ph.D., Associate Professor, Health Services Research, Management and Policy, University of Florida, jharman@ufl.edu

**Research Objective:** Electronic Medical Records (EMRs) are commonly believed to improve the quality of care. Although some studies have found EMRs to improve the quality of care, a previous nationally-representative study found that EMRs were associated with lower treatment rates for depression. EMRs have the potential to improve adherence to treatment guidelines for individuals with anxiety disorders, but EMRs may also have a negative impact on treatment for anxiety disorders. The purpose of this study is to assess whether the likelihood of receiving treatment for anxiety disorders is greater during visits to practices with EMRs compared to practices without EMRs.

**Study Design:** This cross-sectional analysis used data from the 2007-2010 National Ambulatory Medical Care Surveys, a nationally representative sample of physician office visits in the U.S. conducted annually by the National Center for Health Statistics. Logistic regression was used to compare the odds of receiving any anti-anxiety medication and/or any mental health counseling or psychotherapy. All analyses use the survey procedures of Stata 10.0 to allow results to be nationally representative and to account for the complex sampling strategy of the NAMCS, and control for patient demographics, previous visits, practice ownership, the number of co-occurring chronic conditions, and type of insurance.

**Population Studied:** The study includes all visits made by patients with a recorded anxiety disorder diagnosis (N=2,971).

**Principal Findings:** There was no significant difference in the adjusted odds of receiving anti-anxiety medication between EMR and non-EMR practices (OR=0.83, p=.242). However, the adjusted odds of receiving mental health counseling or psychotherapy during a visit for an anxiety disorder at a practice with an EMR was less than half that observed during visits to
practices without an EMR (OR=0.46, p=.001). When the adjusted odds of receiving any anxiety treatment was assessed (either anti-anxiety medication or mental health counseling or psychotherapy), visits by patients to practices with EMRs were significantly less likely to have anxiety treatment offered than visits by patients to practices without EMRs (OR=0.63, p=.025).

**Conclusions:** Similar to what was found previously with depression treatment, anxiety treatment was less likely to be offered during visits to EMR practices. It is possible that the time and effort required by physicians to type information into EMRs during visits or other aspects of EMR design are negatively impacting physicians’ ability to manage all of the conditions of their older patients during limited visit times.

**Implications for Policy, Delivery, or Practice:** Physician practices that implement EMRs should carefully monitor and assess the impact of these systems on patient care and consider improvements in the functionality of these systems, particularly for treatment of mental health conditions.

**Treatment of Obsessive Compulsive Disorder in a Nationwide Survey of Office-Based Physician Practice**

**Presenter:** Jennifer Humensky, Ph.D., Assistant Professor of Clinical Health Policy and Management (in Psychiatry), NYS Center of Excellence for Cultural Competence, Dept of Psychiatry, Columbia University/NYSPI, humensk@nyspi.columbia.edu

**Research Objective:** Obsessive compulsive disorder (OCD) is a chronic condition characterized by obsessions and/or compulsions (e.g., fear of dirt, need for symmetry, compulsive checking). OCD is associated with profound lowered quality of life, social isolation and a large economic burden on society. It is estimated that 2-3 million people are suffering from OCD in the United States. About one in fifty people have had OCD symptoms at some point in their lives. Evidence-based guidelines for the treatment of OCD identify 2 types of efficacious treatments including serotonin reuptake inhibitors (SRIs, i.e., clomipramine and the selective serotonin reuptake inhibitors) and cognitive-behavioral therapy (CBT) consisting of exposure and ritual prevention (EX/RP). Recent research has shown that despite the magnitude of distress and disability associated with OCD, the majority of individuals with OCD are not receiving evidence-based care. The goal of this study is to examine management of outpatient visits with a diagnosis of obsessive compulsive disorder.

**Study Design:** This study comprises a retrospective secondary data analysis of the National Ambulatory Medical Care Survey, a nationally-representative sample of visits provided by non-federally employed office-based physicians in the United States. We examine treatment provided during outpatient visits with a diagnosis of OCD.

**Population Studied:** Persons age 18 years and older who are receiving outpatient visits for OCD (based on ICD-9 code 300.3), from physicians participating in the 2003-2009 NAMCS. Results were weighted and corrected to account for complex sampling.

**Principal Findings:** The population diagnosed with OCD was 51% female and 49% male, and overwhelmingly non-Hispanic white (91%). Only 1.5% were non-Hispanic black, 3% were Hispanic, 5% were other non-Hispanic. Very few were over age 65 (3.5%). The majority were being seen by psychiatrists (88%). Most patients with OCD had been previously seen in the past 12 months by the same physician (96%) with 56% having had 6 or more visits with that physician in the previous 12 months. Preliminary findings indicate that most patients receive medication (85%), primarily SRIs (70%), followed by benzodiazepines (29%), antipsychotics (12%), stimulants (6%) and mood stabilizers (3%). Only 4% reported receiving any psychotherapy, indicating that even fewer are likely to be receiving the intensive EX/RP.

**Conclusions:** The reasons underlying the underutilization of evidence-based treatment for OCD are likely to be multifactorial. Patient-level factors include knowledge about OCD, willingness to seek treatment and preferences for type of treatment. Patients may have limited knowledge about the existence of OCD, and the disorder may impair the ability to recognize the symptoms as a disorder and to seek treatment. Furthermore, EX/RP is time-consuming and resource intensive and some patients may not...
have insurance which covers sufficient treatment. Provider level factors include a lack of trained clinicians, particularly in CBT and EX/RP. System-level factors include the expense of providing specialized, manualized treatment such as EX/RP. Some patients may not have sufficient insurance coverage and some providers might prefer less intensive services that are more easily reimbursed.

Implications for Policy, Delivery, or Practice: Evidence-based OCD treatment is underutilized in office-based physician visits. Identifying the extent of under-utilization is an important first step to identifying ways to promote evidence-based treatment.

An Interactive Tool to Estimate Costs and Resources for a First Episode Psychosis Initiative in New York State

Presenter: Jennifer Humensky, Ph.D., Assistant Professor of Clinical Health Policy and Management (in Psychiatry), NYS Center of Excellence for Cultural Competence and Division of Mental Health Services and Policy Research, Dept of Psychiatry, Columbia University/NYSPHI, humensk@nyspi.columbia.edu

Research Objective: Systems of care, in the US and worldwide, are attempting to meet the challenge of providing early intervention services for individuals experiencing a first psychotic episode, as evidence for the effectiveness of such interventions mount. The New York State Office of Mental Health (OMH) is a partner in the NIMH-funded RAISE Connection Program, which established fully dedicated multi-disciplinary FEP teams providing 2 years of comprehensive treatment. Facilitated by its participation in the RAISE initiative, OMH is exploring how to scale up early intervention services for individuals experiencing psychosis across the state. A central planning issue is estimating the number of treatment teams needed across the state. Because the number of teams needed is driven by so many unknowns, our goal was to create a user-friendly modeling tool that would allow users to input various estimates for these variables, and to see the impact of the estimates on projections of number of teams needed and, correspondingly, costs to operate the teams.

Study Design: This study utilized a state-academic partnership to facilitate needs assessment and cost estimates, by developing an interactive Excel-based planning tool. Our goal was to create a user-friendly modeling tool to allow the user to input various estimates for a set of variables and to see 1) the number of teams that would be needed statewide; 2) how large an area’s population needed to be to support an FEP team; and 3) what such teams would cost to operate under various staffing models.

Population Studied: Simulated costs and needs assessment, based on the US Census data of the population in New York State, both statewide, and by smaller geographical areas within the state.

Principal Findings: The tool provides estimated costs and team needs based on high, low and moderate estimates of a number of input variables, including FEP incidence, percentage of individuals approached and agreeing to enter services, the number of clients a team can support, and the duration of treatment. Based on our moderate estimates, we estimate that a population of about 500,000 is needed to support one team.

Conclusions: By identifying the size of the population needed to support one team, administrators can identify areas with the sufficient population within a reasonable travel distance to base a team. Similarly, any entity bidding on a partially- or fully-capitated contract to provide such services can estimate the number of individuals with FEP for which it would be responsible. Program administrators can use the tool for planning and outreach, to minimize wait lists and to anticipate staffing needs. The flexibility of the tool allows for adaptation to other treatment models, such as hub-and-spoke models or part-time team models.

Implications for Policy, Delivery, or Practice: Because the tool allows a user to specify what may be very local parameters, this tool can be adapted easily for use in other treatment settings and to other team-based treatment modalities. This tool is an example of how the development of a state mental health initiative can be facilitated through an academic partnership.

Access to Mental Health Services among Patients at Health Centers
Emily Jones, Office of Economic Analysis, Evaluation, and Modeling in the Office of the National Coordinator for HIT; Lydie Lebrun-Harris, Health Resources and Services Administration; Alek Sripipatana, Health Resources and Services Administration; Quyen Ngo-Metzger, Agency for Healthcare Research and Quality

Research Objective: The main objectives were to examine mental health treatment needs among health center patients, utilization and care delivery patterns, and patient characteristics associated with both unmet need and satisfaction with mental health treatment provided at health centers.

Study Design: This study used data from the 2009 Health Center Patient Survey to explore the factors associated with unmet need and satisfaction with mental health services provided at health centers. Correlates of unmet need and high satisfaction were explored using multivariate logistic regression models, adjusted for age, gender, race/ethnicity, insurance status, educational attainment, mental health status, usual source of care, unmet need for medical care in the past year, whether the patient received substance abuse treatment in the past year region, and urbanity.

Unmet need for mental health care was defined as either a delay or an inability to access mental health care that the patient or a doctor thought was necessary in the last year. Patient satisfaction with the mental health treatment services that were provided in health centers was measured on a five-point Likert scale. Due to the complex sampling design, weighting was applied, so the results are nationally representative of patients served by health centers in terms of characteristics such as age, race/ethnicity, poverty status, gender, and insurance status.

Population Studied: Federally-qualified health centers comprise one of the largest primary care safety net systems, providing affordable comprehensive care to over 20 million underserved patients annually. The 2009 Health Center Patient Survey was fielded to 4,562 patients from 432 clinic sites between September and December 2009; this study uses data from the 3,949 interviews with adult patients.

Principal Findings: One in five health center patients accessed mental health services from any provider, and about seven percent of health center patients received mental health services at a health center. Most of these patients were satisfied with the care that they received, particularly patients with a usual source of care. Delays and unmet need persisted, particularly among patients lacking a usual source of care and in the South and the West. There were no racial and ethnic disparities in patient satisfaction or unmet need.

Conclusions: The primary care system is the main portal of access to mental health treatment, but barriers still loom large in underserved communities, such as affordability, provider scarcity, and stigma. Providing mental health services in the primary care setting is one way to reduce the unmet need and delays in access to treatment that persist.

Implications for Policy, Delivery, or Practice: Strategies to address unmet need include expanding capacity for behavioral health services in health centers and enhancing the coordination of behavioral health and medical care. Best practices for collaborative care include screening patients for behavioral health disorders in primary care, disseminating evidence-based practice guidelines, enhancing provider training and technical assistance, providing financial incentives, and providing referrals to specialty behavioral health providers in the community. Another strategy is building patient health literacy around mental health issues to inform, engage, and activate patients about behavioral health issues.

Racial and Ethnic Disparities In Behavioral Health Visits With Primary Care Providers and Behavioral Health Specialists
Audrey L. Jones, UCLA Fielding School of Public Health; UCLA Center on Bridging Research Innovation, Training and Education, Training and Strategic Communication on
Disparities in BH visits between Black, White, and Latino adults. This study examines racial/ethnic disparities in behavioral health visits with PCPs and BH specialists from 2005-2010.

**Study Design:** We use panel data from the Medical Expenditures Panel Survey to examine racial/ethnic disparities in BH visits between 2005-2010. Logistic regression and negative binomial regression models were used to estimate disparities in the probability of any outpatient BH visit and the mean number of outpatient visits provided to those with any BH visit. Visits were examined separately for BH services provided by PCPs and BH specialists.

**Population Studied:** The sample included 2,858 adults, age 18 or older, with serious psychological distress. Disparities were examined for Non-Latino White (n=1,494), Non-Latino Black (n=570), and Latino adults of Mexican, Central/South American (n=564) and Caribbean (n=230) heritage.

**Principal Findings:** Racial/ethnic minorities experience disparities in both the access to and continuity of outpatient BH services. Black adults were less than two-thirds as likely as Whites to receive a BH visit with a PCP (RR = 0.60, 95% CI = 0.48-0.74). Among those with any visit to a BH specialist, Blacks received 4.23 fewer visits per year than Whites (95% CI = 2.11-6.38). Latinos of Mexican and Central/South American heritage were less likely than Whites to report any visit with a BH specialist (RR = 0.71, 95% CI = 0.49-0.93). When U.S. and foreign born nativity was examined, foreign born Latinos of Mexican and Central/South American heritage experienced disparities in visits with PCPs (RR = 0.71, 95% CI = 0.48-0.96) and BH specialists (RR = 0.52, 95% CI = 0.30-0.78). Race by time interaction terms were non-significant, indicating that disparities in BH visits for high risk populations have not improved in recent years.

**Conclusions:** Racial/ethnic disparities persist in BH service initiation and follow-up, suggesting that policies are needed to expand access to care, reduce fragmentation of services, and improve the continuity of BH services for minorities at-risk for severe mental illness.

**Implications for Policy, Delivery, or Practice:** The Affordable Care Act is likely to improve access to physical and behavioral health services for Black, White, and Latino adults. Given these increased service demands, PCPs must be given the training and supportive resources needed to screen and treat BH disorders in minority populations. To reduce service disparities, there is a need to improve the coordination of BH services between PCPs and BH specialists. This will require a colocation of physical and BH service providers as well as a restructuring of payment arrangements to incentivize physical and BH services coordination.

**Geographic Variation in Utilization of Mental Health Drugs among Medicare Beneficiaries**

Cameron Kaplan, University of Pittsburgh; Yuting Zhang, University of Pittsburgh

**Presenter:** Cameron Kaplan, Ph.D., Post-doctoral Associate, Health Policy & Management, University of Pittsburgh, ckaplan@pitt.edu
**Research Objective:** To examine geographic variation in the utilization of mental health drugs among Medicare beneficiaries, and how this has evolved over time.

**Study Design:** We calculated various measures of mental health drug utilization among Medicare Part D beneficiaries in the 306 Dartmouth Atlas of Health Care hospital referral regions, 50 states and the District of Columbia, and 4 national regions (South, West, Midwest, and Northeast). We examined variation in total spending on mental health drugs, the proportion of branded medications, as well as utilization of drugs across various therapeutic classes for mental health. We adjusted for differences in patient demographics, insurance status, and clinical characteristics across regions. These measures were then calculated at various points in time to examine changes in utilization associated with new market entry and patent status changes.

**Population Studied:** We used a 5% sample of Medicare part D claims from 2007 to 2010, obtained from the US Centers for Medicare and Medicaid Services’ Chronic Condition Warehouse. In order to properly adjust for clinical characteristics, our main study sample was limited to those who were enrolled in a stand-alone Part D plan.

**Principal Findings:** We found significant variation in the use of mental health drugs across regions. For instance, the ratio of the 75th percentile of mental health drug spending to the 25th percentile was 1.36. This is larger than the variation in antibiotic spending we reported in a previous work (Zhang et al., 2012, Arch Intern Med.). After adjusting for patient characteristics, the Northeast, West, and Midwest had approximately equal spending on mental health drugs, while the South had 16.1% lower spending on these medications than the other three regions. The variation in the use of expensive atypical antipsychotic drugs explained a large amount of the variation in spending across regions.

**Conclusions:** Mental health drugs are some of the most widely used medications among Medicare beneficiaries. For most subclasses of mental health drugs, there are many choices available that vary greatly in cost, but have similar clinical effectiveness. Variation in spending across regions after adjusting for patient characteristics may be indicative of overuse of high-cost medications in some areas.

**Implications for Policy, Delivery, or Practice:** Areas with high spending on mental health drugs may benefit from programs targeted at improving the use of more cost-effective medications.

**Gender Differences in Prescription of Antipsychotics and Mood Stabilizers with Weight Gain Potential among Veterans with Serious Mental Illness**

Eric P. Slade, PhD, VA VISN5 MIRECC and Division of Services Research, Department of Psychiatry, University of Maryland School of Medicine; Julie Kreyenbuhl, University of Maryland School of Medicine; Deborah R. Medoff, PhD, VA VISN5 MIRECC and Division of Services Research, Department of Psychiatry, University of Maryland School of Medicine; Lan Li, MS, Division of Services Research, Department of Psychiatry, University of Maryland School of Medicine; Amy M. Kilbourne, PhD, MPH, VA National SMITREC and Department of Psychiatry, University of Michigan; Lisa B. Dixon, MD, MPH, VA VISN 5 MIRECC and 5Center for Practice Innovations, New York State Psychiatric Institute, Department of Psychiatry, Columbia University

**Presenter:** Julie Kreyenbuhl, Ph.D.,Pharm.D., Associate Professor, Psychiatry, University of Maryland School of Medicine, jkreyenb@psych.umaryland.edu

**Research Objective:** Women veterans are among the fastest growing segments of new health care users in the Veterans Health Administration (VHA). In fiscal year 2010, VHA provided care to over 25,000 women with serious mental illness (SMI) including schizophrenia and bipolar disorder, of whom 63% were prescribed antipsychotic medications (APMs) and 58% mood stabilizer medications (MSMs). Emerging research suggests that women may be more susceptible than men to weight gain and other metabolic side effects of APMs and MSMs and the associated adverse effects on physical health. The objective of this study was to characterize gender differences in prescription of APMs and MSMs according to their weight gain liability.

**Study Design:** We conducted a cross-sectional retrospective study of gender differences in prescription of APMs and MSMs in veterans with SMI receiving care in a Department of Veterans Affairs healthcare network in the U.S. mid-Atlantic region. Administrative health services
utilization and pharmacy records from fiscal year (FY) 2007-11 were the source of data. APMs with low liability for weight gain included aripiprazole, asenapine, fluphenazine, haloperidol, lurasidone, perphenazine, pimozide, and ziprasidone. MSMs with low liability for weight gain included lamotrigine, oxcarbazepine, and topiramate. Multivariable logistic regression analysis was used to examine gender differences in the likelihood of prescription of APMs or MSMs with low versus moderate/high liability for weight gain, adjusting for selected demographic and clinical characteristics.

**Population Studied:** A total of 5,837 male and 974 female veterans with SMI (schizophrenia-spectrum disorders or bipolar disorder) received one or more prescriptions for an APM, and 4,397 male and 903 female veterans with SMI received one or more prescriptions for a MSM, at some point during the 5-year study period.

**Principal Findings:** A larger proportion of female veterans with SMI (49%) received prescriptions for APMs with a low liability for weight gain than males (38%) (p<0.0001). In multivariable analyses, females were more likely than males to be prescribed these treatments (adjusted odds ratio (AOR): 1.47; 95% CI: 1.26-1.73; p<0.0001). Similarly, a greater proportion of female veterans (40%) received prescriptions for MSMs with a lower propensity for weight gain than males (21%) (p<0.0001). In multivariable analyses, female veterans had a higher likelihood than males of being prescribed these agents (AOR: 2.19; 95% CI: 1.7-2.8; p <0.0001).

**Conclusions:** Female veterans with SMI in a single VA healthcare network were more likely to be prescribed antipsychotic and mood stabilizer treatments with a lower risk of weight gain and adverse metabolic effects than males. Whether the apparent preferential use of psychotropic treatments with more benign side effect profiles in female veterans with SMI is more widespread throughout the VHA merits further investigation.

**Implications for Policy, Delivery, or Practice:** The results of this study suggest that prescribing choices for APMs and MSMs by VA mental health prescribers and female veterans with SMI reflect a growing awareness of the potential adverse health consequences of these treatments. Although this suggests women veterans are being subjected to fewer physical health risks from these medications, the precise impact of these treatment decisions on both the physical and mental health of female veterans remains largely unknown.

**Funding Source(s):** VA
patients per case visited and stayed in a medical center under 29 days. 56.9% of total annual out-of-pocket expenses were included under 49,000won and between 50,000won–249,000won. Next, significant variables affecting out-of-pocket expenses were influenced by patient characteristics such as sex, age, main sick, path course of an emergency room, the number of visits. On the other hands, there was no significant difference in visiting an emergency room through a paramedics.

**Implications for Policy, Delivery, or Practice:** Now common negative perceptions, prejudices, and discrimination towards depression and mental illness should be identified early in order to decrease the treatment cost and prevention of long-term illness can be effectively be made as a prerequisite for mental health treatment environment. From 2013, the government is prospected to promote revision of the Mental Health Act in accordance to the lifelong mental health summary initiative and implementation of lifelong mental screening system. Therefore, in order for the government to make a robust and efficient method for the mental wellbeing of the people such as effective prevention program and management, mental health interventions, and mental health-related care instructions, tailored treatment and counseling services, etc. long and sustainable programs need to be developed and implemented.

**Financing Behavioral Health Spending During the Recession: SAMHSA Spending Estimates Through 2009**

Katharine Levit, Truven Health Analytics; Tami L. Mark, PhD, Truven Health Analytics; Rosanna Coffey, PhD, Truven Health Analytics; Sasha Frankel, Truven Health Analytics; Rita Vandivort-Warren, MSW, Health Resources and Services Administration (formerly of SAMHSA); Patricia Santora, PhD, Substance Abuse and Mental Health Services Administration; Kevin Malone, Substance Abuse and Mental Health Services Administration

**Presenter:** Katharine Levit, B.A., Director, Behavioral Health and Quality Research, Truven Health Analytics, katharine.levit@truvenhealth.com

**Research Objective:** The Substance Abuse and Mental Health Services Administration (SAMHSA), has been developing estimates of national spending on mental health and substance abuse treatment for many years. We update the national behavioral health spending estimates through 2009 to capture the impact of the recession. We also re-examine other short-and long-term trends in mental health and substance abuse financing.

**Study Design:** The methods used to construct behavioral health spending estimates are consistent with the CMS National Health Expenditure Accounts framework and methods. The first method used SAMHSA survey results to estimate spending by payer for specialty behavioral health providers. For all other providers, the share of all-health use for behavioral health treatment—adjusted for differences in average charges and cost sharing—was estimated. This share was applied to the CMS all-health spending estimates. The results from both methods were summed after removing any duplication in spending between them.

**Population Studied:** U.S. population.

**Principal Findings:** Behavioral health treatment expenditure growth slowed during the recession (2007–2009); it increased at a 4.3% average annual rate, which was down from 6.1% in the pre-recession (2004–2007) period. Private spending increased 7.2% in the pre-recession period and 2.7% during the recession, while public spending growth continued to increase at its pre-recession pace (5.4% and 5.3%). The behavioral health share of all-health spending fell from 9.4% in 1986 to 7.4% in 1998. This trend reflects behavioral health spending growth that lagged behind the average increases in all-health spending. From 1998 through 2009, the behavioral health share of all-health spending remained unchanged at 7.4%. Substance abuse treatment spending accounted for 14% of behavioral health spending in 2009 and amounted to $24 billion. In almost every year between 1986 and 2009, substance abuse treatment spending grew at a slower pace than all-health treatment spending.

**Conclusions:** Spending on behavioral health treatment slowed during the recession, which was similar to trends in all-health spending. Diverging public and private growth trends resulted from expanding Medicaid and falling private insurance enrollment. The enhanced federal Medicaid match reduced the state share of Medicaid spending, preventing drastic cuts in...
state-funded behavioral health programs through 2009. However, delayed effects of the recession on states' behavioral health funding raise new post-2009 concerns.

**Implications for Policy, Delivery, or Practice:**
Under the ACA, approximately 11 million previously uninsured adults who also have a substance use disorder or experience serious psychological distress will become eligible for insurance exchanges or Medicaid coverage. Medicaid and private insurance will likely see permanent one-time upicks in their level of demand for services. It will be important to track changes in the level of behavioral health spending and funding sources for unintended consequences of PPACA. If people without health insurance continue to use hospitals and specialty mental health and substance abuse centers as their main providers of behavioral health treatment, these providers could potentially see funding deteriorate as Medicare and Medicaid Disproportionate Share Hospital payments are cut and as cash-strapped states continue reduced funding levels of behavioral health authorities.

**Funding Source(s):** Other, Substance Abuse and Mental Health Services Administration

**Performance of HEDIS Behavioral Health Measures in Commercial Health Plans**
Junqing Liu, National Committee for Quality Assurance; Jeremy Gottlich, National Committee for Quality Assurance; Mary Barton, National Committee for Quality Assurance; Robert Saunders, National Committee for Quality Assurance; Sarah Hudson Scholle, National Committee for Quality Assurance

**Presenter:** Junqing Liu, Ph.D., MSW, Research Scientist, Research, National Committee for Quality Assurance, liu@ncqa.org

**Research Objective:** Behavioral health problems are common, costly and debilitating. Measuring and reporting on quality offers an opportunity to identify gaps in care and drive improvement. This study assessed change in health plans’ performance on behavioral health care over time by using NCQA’s measures.

**Study Design:** This study used commercial health plan data reported to NCQA from 2007 to 2011. Plans reporting data must meet data verification rules and undergo an independent audit. This study aggregated data across all commercial plans to produce performance means. We studied four measures:
- Antidepressant Medication Management among adults with depression
- Follow-Up Care for Children Prescribed ADHD Medication
- Follow-Up after Hospitalization for Mental Illness for member 6 years and older
- Initiation and Engagement of Alcohol and Other Drug Dependence Treatment for members age 13 and older.

**Population Studied:** This study included 410 commercial plans (including health maintenance organizations and preferred provider organizations) from across the United States. The median plan enrollment is 97,722 members, where the 25th percentile is 37,434 and the 75th percentile is 282,209.

**Principal Findings:** Mental health measures showed moderate performance and modest improvements over time. The mean percentage of patients with new episodes of depression treatment who remained on an antidepressant for the 84-day acute phase increased from 62.9 percent (s.d. = 5.9) in 2007 to 65.6 percent (s.d. = 6.5) in 2011; the rate increased from 45.1 percent (s.d. = 6.8) to 49.5 percent (s.d. = 7.0) for the 180-day continuation phase. The proportion of children receiving follow-up visits within the first month of being prescribed ADHD medication increased from 33.7 percent (s.d. = 7.7) to 39.4 percent (s.d. = 7.8); the percentage increased from 38.7 percent (s.d. = 10.3) to 44.2 percent (s.d. = 10.4) for the 9-month continuation phase. Follow up after hospitalization for mental illness had higher performance rates and less improvement over time: the rate of members having a follow-up visit within 7 days of hospitalization increased from 55.6 percent (s.d. = 13.1) in 2007 to 58.9 percent (s.d. = 12.9) in 2011. Within 30 days of hospitalization, the rate increased from 74.0 percent (s.d. = 10.3) to 76.5 percent (s.d. = 10.5). There was a decline in achievement of the only substance use quality measure: the proportion of members who initiated treatment after an episode of substance abuse decreased from 44.5 percent (s.d. = 7.4) to 40.2 percent (s.d. = 7.51), and the rate for engagement in treatment remained at 15.2 percent (s.d. = 5.7) over five years.

**Conclusions:** There were incremental improvements in performance on mental health quality measures among commercial plans but declines in achievement of substance use treatment measures. Substantial gaps in the quality of behavioral health care remain.
Implications for Policy, Delivery, or Practice:
In recent years, measuring and reporting on behavioral health quality measures have revealed some improvements in care, but continue to show room for improvement. Broader efforts to address the lack of progress in improving quality for behavioral health are needed.

Poster Session and Number: B, #588

Costs and Feasibility of Providing Follow-Up Services to Improve Continuity of Care for Suicidal Individuals in Emergency Departments
Chelsea Lyons, University of Rochester Medical Center; Greg Brown, PhD, University of Pennsylvania School of Medicine; Glenn Currier, MD, MPH, University of Rochester School of Medicine and Dentistry; Barbara Stanley, PhD, Columbia University College of Physicians & Surgeons; Kerry Knox, MS, PhD, University of Rochester School of Medicine and Dentistry

Research Objective: The current objective is to determine the feasibility of obtaining cost data for services that work to facilitate outpatient mental health care for people at risk for suicide, following an emergency department (ED), urgent care visit, or hospital visit in diverse health system settings. Additional goals include evaluating these costs, both in terms of immediate cost of facilitation and downstream costs that may be incurred from greater demand for outpatient care.

Study Design: EDs often serve as an initial and sole treatment setting for suicidal individuals, representing a targeted setting to prevent deaths from suicide. These patients are at increased risk for suicide following acute care (McCarthy et al., 2009) and investigators have pointed out that there may be a critical gap in providing outpatient services after these individuals are seen in ED settings, possibly leading to future need for additional acute services.

One example of an attempt to deliver continuous care that has recently been reported (Knox et al., 2012), was a clinical demonstration project implemented in Veterans Affairs (VA) EDs and urgent care facilities: Suicide Assessment Follow-up Engagement: Veteran Emergency Treatment (SAFE VET). This intervention combined Safety Planning (Stanley & Brown, 2008) - a promising ED-based treatment for suicidal individuals - with structured follow-up addressing risk and safety assessment, and treatment linkage. Follow-up was provided by Acute Service Coordinators who worked closely with ED clinicians and outpatient mental health staff.

The cost of intervention designed to link patients into outpatient care is generally unknown. In practice, this type of service is likely to be considerably labor intensive, as often the target population does not access the mental health or medical system on a consistent basis. Examining cost data across a variety care settings, both within the VA and non-VA health settings, will provide a better understanding of the resources involved in promoting continuity of care following an ED visit for suicidality.

Population Studied: Patients presenting to either VA or a non-VA ED or urgent care setting, expressing suicidal ideation or behavior but do not require immediate hospitalization and who are typically classified as moderate suicidal risk.

Principal Findings: Intensive follow-up contacts with at-risk patients may be effective in engaging them into outpatient care. The findings on the cost of implementing SAFE VET and other ED-based follow-up interventions are still forthcoming. The feasibility of accessing this data in VA and non-VA settings presents various challenges, especially given the often transient nature of the population of interest. Even so, this type of data can be obtained.

Conclusions: Intensive follow-up contacts may be an effective means for reducing morbidity and mortality from suicide. In improving quality of care through increased continuity from acute to outpatient psychiatric care, costs may also be reduced.

Implications for Policy, Delivery, or Practice:
The practice of providing intensive follow-up through telephone or direct contact, may be transferable to a wide variety of VA and non-VA emergency departments and urgent care centers to improve outcomes for individuals at risk for suicide after discharge from hospital or ED settings. Doing so may also be cost-effective for health systems.

Funding Source(s): VA
Poster Session and Number: B, #589
**Axis II Psychiatric Disorders and High Cost Health Care Utilization**

J. Catherine Maclean, University of Pennsylvania; Haiyong Xu, University of California at Los Angeles; Michael T. French, University of Miami; Susan Ettner, University of California at Los Angeles

**Presenter:** J. Catherine Maclean, Ph.D., Assistant Professor, Medical Ethics and Health Policy, University of Pennsylvania, maclean@upenn.edu

**Research Objective:** Despite interest in how clinical conditions such as substance abuse, depression, and anxiety impact health care utilization, little is known about the role of Axis II (A2) psychiatric disorders. A2 disorders are a prevalent, yet poorly understood class of conditions that lead to diminished social functioning and impose substantial costs on both the disordered person and those with whom he interacts. The objective of this study is to rigorously analyze the associations between A2 disorders and two measures of health care utilization with relatively high cost, emergency department (ED) episodes and hospital admissions, in a large and nationally representative data set specifically designed to measure psychiatric conditions.

**Study Design:** We estimate logistic regression models that adjust for a rich set of covariates associated with health care utilization. Separate models are estimated for men and women. We construct three sets of A2 disorder variables: 1) any disorder, 2) one disorder and two or more disorders, and 3) unique indicators for the ten disorders classified by the American Psychiatric Association. Thus, we are able to test for a dose-response relationship (i.e., are higher levels of disorder linked with higher risk for health care utilization?) and whether the relationship varies across A2 disorder type.

**Population Studied:** A nationally representative sample of adults 20 to 90 years of age drawn from Wave II (2004/2005) of the National Longitudinal Survey of Alcohol and Related Conditions (NESARC). The survey response rate is 65% in Wave II (N=34,653).

**Principal Findings:** Both men and women with A2 disorders are at elevated risk for ED episodes and hospital admissions. These associations are robust to adjustment for confounding factors, including demographics, access to health insurance, health behaviors, chronic physical health conditions, Axis I disorders, suicide attempts, and injuries. We find evidence of a dose-response relationship, and document that the relationship varies substantially across A2 disorder type with borderline disorder displaying the strongest association with health care utilization.

**Conclusions:** Our findings show that A2 disorders, particularly borderline disorder, are important risk factors for ED episodes and hospital admissions for both men and women. Our results are timely, as containing health care costs is crucial to the long-term solvency of publicly provided health insurance programs.

**Implications for Policy, Delivery, or Practice:** Health policy makers should consider tailoring health interventions to the specific features of A2 disorders. Substance abuse treatment providers have adopted this strategy, and have improved treatment outcomes for patients affected by A2 disorders. Based on our findings, borderline disorder displays the strongest association with hospital admissions and ED visits for both men and women. Although all A2 disorders are notoriously difficult to treat, borderline may be the most responsive condition. A set of clinical studies finds that dialectical behavioral therapy (DBT) can lead to improved social functioning among persons affected with borderline disorder. If health care providers diagnose borderline, perhaps DBT or another evidence-based treatment should be initiated to address both the A2 disorders and related health care utilization.

**Economic Fluctuations and Drug Abuse Treatment: Evidence from Admissions Data**

J. Catherine Maclean, University of Pennsylvania; Jonathan H. Cantor, New York University; Rosalie Liccardo Pacula, RAND Corporation

**Presenter:** J. Catherine Maclean, Ph.D., Assistant Professor, Medical Ethics and Health Policy, University of Pennsylvania, maclean@upenn.edu

**Research Objective:** The objective of this study is to analyze the effect of economic fluctuations on admissions to drug abuse treatment. Although there is a substantial literature on the relationship between economic fluctuations and health, few studies have investigated whether use drug use, particularly illicit drug use, varies across the business cycle. The available
findings are mixed and do not provide sufficient information for development of effective policy. Admissions to drug treatment capture a highly problematic level of drug use, thus they are an interesting outcome from a public health perspective. Further, drug abuse treatment represents a direct financial burden on the public: spending on drug abuse treatment is predicted to reach $35 billion by 2014, and public payers will cover 83% of these costs. **Study Design:** We construct measures of total admissions, and admissions by sex, employment status, race/ethnicity, age, referral source, time period, and drug type by state and year. We estimate regression models that adjust for a rich set of covariates associated with admissions to drug treatment. Because changes in admissions may be driven by the demand for, and supply of, treatment, we include supply side proxies in our regressions and isolate the role of demand. We investigate the role of both household income and health insurance coverage. Finally, we explore how the relationship varies across the distribution of admissions using unconditional quantile regression. **Population Studied:** The Treatment Episode Data Set (TEDS) contains the near universe of drug abuse treatment admissions that receive funding from the Federal or state government, or are certified by the state to provide drug abuse treatment. The TEDS contain approximately 33 million admissions to drug treatment between 1992 and 2010. **Principal Findings:** Admissions to drug treatment decrease in economic downturns; and the relationship is largely attributable to changes in demand for treatment. We identify heterogeneity by client characteristics, drug type, referral source, and time period, and show that changes in household income and health insurance explain at most 11% of the relationship between economic fluctuations and admissions. Finally, unconditional quantile regressions reveal that the relationship varies across the admissions distribution: our findings are largely driven by observations with lower admission rates. **Conclusions:** This study provides, to the best of our knowledge, the first estimates of the effect of economic fluctuations on admissions to drug abuse treatment using U.S. data. **Implications for Policy, Delivery, or Practice:** Policy makers may find our results informative. Because we show that overall admissions decrease during downturns, and these changes are mainly attributable to demand for treatment, funding for drug abuse treatment may be an area that does not need to be expanded when the economy contracts and tax-based revenues decline. Our findings suggest that the relationship between economic fluctuations and drug abuse admissions has changed over time, thus when considering how economic fluctuations impact drug use, and perhaps other health behaviors and outcomes, policy makers should rely on recent data whenever possible as older studies may no longer provide accurate information. **Funding Source(s):** No Funding **Poster Session and Number:** B, #591 **Does Leaving School in a Bad Economy Affect Body Weight?: Evidence from Panel Data** J. Catherine Maclean, University of Pennsylvania **Presenter:** J. Catherine Maclean, Ph.D., Assistant Professor, Medical Ethics and Health Policy, University of Pennsylvania, macleanc@upenn.edu **Research Objective:** In this study I test whether leaving school in a bad economy persistently affects body weight. Several empirical patterns motivate this research. Workers who leave school in a bad economy persistently earn lower wages and work in less prestigious jobs, labor market outcomes are associated with health outcomes, and business cycles have short run effects on health. Recent work shows that leaving school in a bad economy persistently affects mental and physical functioning. Understanding risk factors for elevated body weight is important for improving population health and containing medical costs. According to the Surgeon General, obesity has reached epidemic proportions in the United States. The most recent data suggest that 35.7% of men and 35.8% of women are obese and if recent trends continue, 42% of Americans will be obese by 2030. Obesity is a leading cause of preventable death and contributes to a host of morbidities including Type II diabetes, asthma, cancer, and heart disease, and raises medical care costs by $190.2 billion per year. **Study Design:** I examine three measures of body weight at age 40: body mass index (BMI), overweight (BMI >= 25), and obesity (BMI >= 30). Data are drawn from the National Longitudinal Survey of Youth 1979 Cohort
School-leaving is defined by school completion, and includes both graduates and drop-outs. I proxy economic conditions at school-leaving with the state unemployment rate, and exploit variation generated by volatility in the U.S. business cycle between 1976 and 1992 to identify body weight effects. Because the severe recession of the early 1980s lies within this time period, I effectively compare cohorts that left before, during, and after this recession. To address the potential endogeneity of the time and location of school-leaving, I instrument the school-leaving state unemployment rate. I estimate sex-specific equations given the different labor market participation patterns of men and women.

**Population Studied:** A nationally representative sample of adults aged 40 years drawn from the National Longitudinal Survey of Youth 1979 Cohort.

**Principal Findings:** My results suggest that leaving school in a bad economy persistently affects body weight, and the relationship varies by sex: men who leave school in a bad economy have lower bodyweight, and are less likely to be overweight and obese at age 40 than otherwise similar men. Alternatively, women who leave school when the unemployment rate is high are more likely to be overweight at age 40. Results are larger and more precisely estimated after correctly for the endogeneity of economic conditions at school-leaving. I find suggestive evidence that the body weight effects operate through the labor market and marriage market.

**Conclusions:** Economic conditions at school-leaving have a persistent effect on bodyweight, although the relationship varies by sex.

**Implications for Policy, Delivery, or Practice:** These findings suggest the consequences of the 2007 to 2009 recession may include persistently higher weight for women, but not men. Alternatively, women who leave school when the unemployment rate is high are more likely to be overweight at age 40. Results are larger and more precisely estimated after correctly for the endogeneity of economic conditions at school-leaving. I find suggestive evidence that the body weight effects operate through the labor market and marriage market.

**The Challenge – Detecting Depression in Primary Care**

Racheli Magnezi, Bar Ilan University; Saralee Glasser, MA, Gertner Institute for Epidemiology and Health Policy Research, Sheba Medical Center, Tel Hashomer, Israel; Hadar Shalev, MD, Department of Health Policy and Management, Ben Gurion University of the Negev, Beer Sheva, Israel; Asher Sheiber, MD, Department of Health Policy and Management, Ben Gurion University of the Negev, Beer Sheva, Israel;

**Presenter:** Racheli Magnezi, Ph.D., M.B.A., Head, Health Systems Management Program, Management, Bar Ilan University, magnezir@gmail.com

**Research Objective:** The research objectives were to assess the degree of depression (PHQ-9) among patients attending primary care clinics, evaluate the association of depression with patients’ sense of quality of life (SF-12), and patients’ active involvement in their healthcare, and to compare two screening methods for depressive symptoms (face-to-face and telephone interview). The study design also offered an opportunity to consider the extent of undiagnosed depression by comparing the physicians’ clinical assessment of patients’ level of depression with the patient-rated PHQ-9 scores.

**Study Design:** The survey included 278 patients visiting two primary care clinics. Subjects were interviewed face-to-face in the waiting room or by telephone. They completed three questionnaires that evaluated depression level (PHQ-9), quality of life (SF-12) and self-involvement (PAM) in healthcare (knowledge, skill and confidence in managing chronic health conditions). A PHQ-9 score of 10 or more indicates at least moderate depression. Participating physicians were asked to assess depression in each patient as “diagnosed”, “suspected”, or “not depressed”. They were blinded regarding the patients’ PHQ-9 scores.

**Population Studied:** Subjects included patients aged 18 years and older, who visited two large primary care clinics, in Beer Sheva, Israel, during February 2011.

**Principal Findings:** 177 patients completed the interview face-to-face and 101 by telephone. Based on PHQ-9 scores of 10 or more, 23.4% of subjects reported at least moderate depression, with no difference between the two interview methods. Negative correlations were found between PHQ-9 scores and SF-12 and PAM scores \( r = -0.78, r = -0.35, p < 0.0001 \), respectively. Analysis of covariance (ANCOVA) revealed that SF-12 and PHQ-9 scores were strong predictors of the PAM score \( F \) value 38.2 for the SF-12 and 23.9 for the PHQ-9). However,
when both were entered into the model, only the SF-12 was a significant predictor (F value 13.6). According to the PHQ-9, 78% of patients who scored less than 10 on the PHQ-9 were also considered by their physician as “not depressed.” While nearly half of those whose PHQ-9 score indicated depression were not considered by their physician to be depressed (hidden depression). About 20% of those with a PHQ-9 score less than 10 were suspected or considered to be depressed by the physician. Only 55% of those with a PHQ-9 greater than 10 were diagnosed as depressed by their physician.

Conclusions: Improved awareness and identification of depression by primary care physicians could lead to increased recognition of emotional distress, improved quality of life, and patients’ increased involvement in their own healthcare, thereby enhancing compliance with treatment. Face-to-face interviews were more acceptable to patients than were telephone interviews.

Implications for Policy, Delivery, or Practice: Cognitive and supportive interventions could lead to greater patient involvement in improving their own health. Providing continuing education to physicians on topics related to mental health could lead to greater awareness of and accuracy in diagnosing depression.

An Evaluation of the Cost Effectiveness of XR-NTX Against Existing Treatments for Opioid Dependence
Heide Jackson, University of Wisconsin - Madison; Kara Mandell, University of Wisconsin, Madison; Kimberly Johnson, University of Wisconsin - Madison/NIATx; Debanjana Chatterjee, University of Wisconsin - Madison; David Vanness, University of Wisconsin - Madison

Presenter: Kara Mandell, Doctoral Student, Population Health Studies, University of Wisconsin, Madison, kmandell@wisc.edu

Research Objective: In October 2010, the Food and Drug Administration (FDA) approved extended-release naltrexone (XR-NTX) for the treatment of opioid dependence. The goal of this study is to conduct a cost effectiveness analysis of XR-NTX compared to existing pharmacological treatments (methadone and buprenorphine maintenance treatments) for the treatment of opioid dependence.

Study Design: A discrete state Markov model was used to estimate the payer costs for administering methadone, buprenorphine, or XR-NTX per opioid free day in a simulated cohort of US adult males over a six month period. Deploying a Markov model allows us to overcome many difficulties of assessing outcomes using only clinical trial data—we are able to explicitly model transitions into and out of pharmacological treatment and abstinence within and outside of treatment. Model assumptions, transition probabilities and other data included in the model were based on published literature. Meta-analyses were used when possible. However, because there are only two Phase III clinical trials of XR-NTX, we estimated the model separately using the data from each trial.

Population Studied: The model simulates the experience of a hypothetical cohort of opioid dependent American males age 18-65 who enroll in one of three pharmacological treatments. Opioid use and adherence to treatment are simulated for a six month period.

Principal Findings: Based on our model for 24 weeks, patients are expected to remain in treatment and abstain from opioids approximately 32% of the study period when treated with methadone, 27% of the study period when treated with buprenorphine, and either 30% or 54% (depending on the study data used) of the study period when treated with XR-NTX. Methadone dominates buprenorphine; patients receiving methadone have more opioid free days (37% of days opioid free compared to 32%) and methadone is less expensive to administer than buprenorphine ($1.18 per day compared to $13.52). Using retention and abstinence rates from a study based in the U.S., XR-NTX is dominated by methadone (32% of days opioid free compared to 30%). However, using retention and abstinence rates from a study based in Russia, XR-NTX is cost effective (incremental cost effectiveness ratio [ICER] $4.50 per additional opioid free day).

Conclusions: We find that XR-NTX is not cost effective in a simulated cohort of U.S. males ages 18-65 in the period studied, although it is cost effective in Russia. Our study suggests that methadone is the most cost effective treatment for opioid dependence in the United States.

Implications for Policy, Delivery, or Practice: XR-NTX is not cost-effective for the majority of
the U.S. population. However, limitations in the availability of both methadone and buprenorphine make XR-NTX an important addition to the options available to treat opioid addiction. Though XR-NTX may not be a cost effective treatment at the population level, there is much that is left unstudied concerning special populations and social and patient costs that may have different outcomes.

**The Characteristics and Outcomes of Patients Treated with Buprenorphine**

Tami Mark, Truven Health Analytics

**Presenter:** Tami Mark, Ph.D., M.B.A., Senior Director, Analytic Consulting And Research Services, Analytic Consulting and Research Services, Truven Health Analytics, tami.mark@truvenhealth.com

**Research Objective:** Addiction to opioids has become an epidemic in the United States. Unintentional poisoning causes 87 people to die each day, and over 90% of these are caused by drugs—primarily opioids (“painkillers). In 2011 nationwide, 4.6 percent of persons aged 12 or older reported using pain relievers nonmedically in the past year. Buprenorphine became available to treat opioid addiction in 2002. In 2011, sales of buprenorphine reached over $1 billion dollars. Given the rapid changes in the nature and prevalence of opioid abuse, more research is needed to understand how and for whom buprenorphine is being prescribed and its effectiveness in “real world” settings. The purpose of this investigation is to describe the characteristics and outcomes of individuals who filled prescriptions for buprenorphine.

**Study Design:** The data were from the Truven Health MarketScan® Commercial Claims and Encounters Database, the MarketScan Medicare Supplemental and Coordination of Benefits Database, and the MarketScan Multi-State Medicaid Database for the years 2007–2009. The MarketScan Commercial database includes insurance claims from approximately 20–30 million employees and dependents annually who are covered by large self-insured employers and regional health plans. The MarketScan Medicare Supplemental database includes approximately 2 million beneficiaries who receive insurance coverage through Medicare and current or former employers. The MarketScan Medicaid database contains claims from approximately 6 million beneficiaries annually from several geographically dispersed States. The characteristics, outcomes, and utilization patterns of the individuals filling prescriptions for buprenorphine were compared to an age- and sex-matched sample 6 months before and 6 months after buprenorphine initiation. Statistical testing was done using chi-square tests or t tests.

**Population Studied:** The primary study population consisted of patients who filled prescriptions for buprenorphine.

**Principal Findings:** Buprenorphine recipients had a high prevalence of comorbidities associated with chronic pain, including back problems (42%), connective tissue disease (24%–27%), and nontraumatic joint disorders (20%–23%). Approximately 69% of recipients filled prescriptions for opioid agonist medications in the 6 months before buprenorphine initiation. Buprenorphine recipients were frequently diagnosed with anxiety (23%–42%) and mood disorders (39%–51%). They filled prescriptions for antidepressants (47%–56%) and benzodiazepines (47%–56%) at high rates. Surprisingly, only 53%–54% of patients filling a prescription for buprenorphine had a coded opioid abuse/dependence diagnosis. Buprenorphine treatment was associated with a reduction in hospitalizations, emergency department utilization, and opioid prescription fills, but the rate of these outcomes remained relatively high.

**Conclusions:** This study reveals that patients who receive buprenorphine are a complex population characterized by high rates of diagnoses associated with chronic pain, such as back, joint, and connective tissue disorders; extensive use of opioid medications (both before and after starting buprenorphine treatment); high rates of hospitalization and ED use; and a noteworthy prevalence of psychiatric comorbidities and psychiatric medication prescriptions. These characteristics apply to both the population with private insurance and those with Medicaid.

**Implications for Policy, Delivery, or Practice:** These results highlight the need for research on ways to improve outcomes from buprenorphine treatment in real-world settings.

**Poster Session and Number:** B, #595
Integrating Substance Abuse Treatment into HIV Care: Missed Opportunities in the AIDS Drug Assistance Program

Erika Martin, University at Albany-SUNY; Karen H. Wang, Yale University School of Medicine

Presentation: Erika Martin, PhD, MPH, Assistant Professor, Rockefeller College of Public Affairs & Policy, University at Albany-SUNY, emartin@albany.edu

Research Objective: HIV-infected individuals have a substantial burden of co-morbid substance use disorders, and untreated licit and illicit drug dependencies among people living with HIV contribute to worse HIV care outcomes and increased HIV transmission. We assessed the availability of guideline-concordant medication-assisted therapies to treat substance use disorders on state-administered AIDS Drug Assistance Programs (ADAPs), an important source of drug coverage for low-income HIV patients. We examined the frequency and variation of medication-assisted therapies across state formularies.

Study Design: We collected state ADAP formulary data from 1997 to 2009 from the ADAP annual reports published by the National Alliance of State and Territorial AIDS Directors. We systematically reviewed formularies and compared them to guideline-concordant medication-assisted therapies to treat substance use disorders on state-administered AIDS Drug Assistance Programs (ADAPs), an important source of drug coverage for low-income HIV patients. We examined the frequency and variation of medication-assisted therapies across state formularies.

Population Studied: We analyzed ADAP programs in the 50 states and District of Columbia.

Principal Findings: The most frequently included medication-assisted therapies were those to treat tobacco dependence, followed by medications to treat opioid dependence. Few state ADAPs covered alcohol dependence medications. By 2009, less than 20 percent of states ever had a complete formulary for at least one of the three conditions, and less than 10 percent ever had a complete formulary for all three conditions simultaneously. States did not consistently retain medications on their formularies after their initial adoption, and in any given year, less than one tenth of states covered the complete set of recommended medications for at least one condition, and less than half of states covered a partial formulary for at least one condition.

Conclusions: ADAPs could provide access to medication-assisted therapies for SUD for a significant number of HIV-infected individuals, but these medications have not been widely covered throughout the program’s history. Furthermore, HIV-infected individuals’ state residence affects their coverage for SUD treatment, which may impact health outcomes. Increased availability of medication-assisted therapies through ADAP could facilitate integrated HIV and SUD care. Integrating these medical services will be necessary to meet the National HIV/AIDS Strategy’s goals to increase access to care, improve health outcomes, and reduce new infections.

Implications for Policy, Delivery, or Practice: Although there are clinical and policy recommendations for integrated SUD and HIV treatment, payment issues including complex funding streams are a barrier. Our results reveal a large disconnect between clinical guidelines and program decisions, as well as large disparities across states. Reviewing the availability of medication-assisted therapies to treat SUD on public formularies is important for understanding structural barriers to treatment, and identifying geographic inequities in access to treatment.

Collaborative Chronic Care Models: Review and Meta-Analysis to Guide Research and Policy

Christopher Miller, VA Boston Healthcare System; Mark Bauer, MD, VA Boston Healthcare System

Presentation: Christopher Miller, Ph.D., Psychology Postdoctoral Fellow, Center for Organization, Leadership, and Management Research, VA Boston Healthcare System, christopher.miller8@va.gov

Research Objective: Collaborative chronic care models (CCMs) improve outcome in chronic medical illnesses and depression treated in primary care. Through a systematic review, meta-analysis, and meta-regression, we aimed to extend this work by investigating the utility of CCMs for several
outcome domains across mental health conditions.

**Study Design:** Study Design: Through systematic review, randomized controlled trials (RCTs) of CCMs versus other care delivery models were identified via an extensive literature search. CCMs were defined a priori as interventions with at least three of the six elements identified in Improving Chronic Illness Care: patient self-management support, clinical information systems, delivery system redesign, decision support, organizational support, and community resource linkages. Data extraction included population/setting factors, trial implementation characteristics, intermediate clinical processes, mental health symptoms, quality of life, social role function, and cost. Follow-up analyses on depression and QOL were subjected to cumulative meta-analysis and meta-regression.

**Population Studied:** Population Studied: Data were extracted from 57 trials (161 total analyses) reported in over 70 peer-reviewed articles. Trials were conducted in a variety of different types of clinics and healthcare systems, and were also diverse at the patient level in terms of common demographic variables such as age, gender, and ethnic minority status.

**Principal Findings:** Principal Findings: Metanalysis indicated significant overall effects across disorders and care settings in depression, mental and physical quality of life, and social role function (d=0.20-0.33). Total healthcare costs did not differ from controls conditions. Cumulative meta-analyses indicated that effect sizes favoring CCM for outcome domains of depression, mental quality of life (QOL), and physical QOL have stabilized. Four of six CCM elements (patient self-management support, clinical information systems, system redesign, and provider decision support) were common among reviewed RCTs, while the remaining two elements (healthcare organization support in the context of community resource linkages) were rare. Meta-regression indicated that a single CCM element was statistically associated with the success of the model, and meta-regression did not identify specific factors associated with CCM effectiveness. Nonetheless, results within individual trials suggest that CCMs may be most effective for patients with at least moderately severe symptoms.

**Conclusions:** Conclusions: CCMs can improve mental and physical outcome for individuals with various mental disorders across a wide variety of care settings, with effects derived primarily from four original CCM elements.

**Implications for Policy, Delivery, or Practice:** Implications for Policy, Delivery or Practice: CCM effect sizes for major outcome domains have stabilized. Indicate that the CCM framework is robust and broadly applicable across settings and across mental health diagnoses. Despite the scant attention paid to healthcare organization support in the context of RCTs, implementing and sustaining this established model will likely require this CCM element. While CCMs have typically been tested as population-based interventions, evidence supports stepped care application to patients with more severe illness. Future priorities include developing implementation strategies to support adoption and sustainability of the model, and maximizing fit of this multi-component framework to fit the local environment.

**Opioid-Related Emergency Department Visits and Hospital Admissions in Maryland**

Patience Moyo, University of Maryland Baltimore; Ting-Ying Huang BSPharm, University of Maryland Baltimore; Yu-Jung Jenny Wei PhD, University of Maryland Baltimore; Linda Simoni-Wastila PhD, University of Maryland Baltimore; Jeanne Yang MCP, University of Maryland Baltimore; Corinne Woods MPH RPh, University of Maryland Baltimore

**Presenter:** Patience Moyo, B.A., Graduate Student, Pharmaceutical Health Services Research, University of Maryland Baltimore, pmoyo@umaryland.edu

**Research Objective:** Drug abuse is a major public health concern in the United States. While the use of heroin and other illicit drugs remains problematic, the misuse and abuse of prescription opioids drives much of the recent increase in fatal and non-fatal drug poisonings and overdoses. According to the Centers for Disease Control and Prevention, nearly 75% of prescription drug overdoses are caused by opioids. Opioid use, whether for medically-indicated or recreational purposes, can lead to adverse consequences that result in emergency department (ED) visits or hospitalization. The objective of this study is to examine the prevalence and trends of opioid-related ED visits.
and hospital admissions across the state of Maryland.

**Study Design:** We examined county-level changes in opioid-related hospital admissions using Maryland Health Services Cost Review Commission (HSCRC) data. Opioid-related visits constituted diagnoses of accidental opioid poisoning, opioid dependence, and nondependent opioid abuse identified using International Classification of Diseases, ninth revision [ICD-9-CM] codes 304.0, 304.7, 305.5, 305.6, E850.0-E850.2. Both prescription and illicit opioids, including heroin, were captured. The results were expressed as opioid-related visits as a proportion of: (1) all visits and (2) all substance-related visits. Substances in substance-related hospital and ED visits included alcohol, cocaine, cannabis, and amphetamines. Geographic information system software (ArcMap) was used to map the changes in the frequency of ED visits and hospitalizations at the county level.

**Population Studied:** Patients who were admitted at least once to the hospital or at least one ED visit at any one of at least 49 hospitals in Maryland.

**Principal Findings:** In 2010, Maryland experienced 1,983,961 total ED visits and 696,463 total hospital admissions. The proportion of ED visits involving any substance was 1.6%; 0.4% of all ED visits were opioid-related. The proportion of hospitalizations that were substance-related was 7.3%, and 3.4% were opioid-related. Opioids comprised a considerable proportion of substance-related hospitalizations (46.2%) and ED visits (26.9%). The majority of patients admitted to the hospital with an opioid-related diagnosis were male (nearly 60%), middle age (mean age=43 years), and nearly equal proportions were white and black. Analysis of the 24 jurisdictions in Maryland in 2010 revealed 19 had increased proportions of opioid-related hospital admissions from 2009. Counties in the Eastern Shore experienced both the greatest increases (1.2% in both Queen Anne’s and Kent) and reductions (-0.34% in Wicomico and -0.21% in Talbot) of opioid-related hospital admissions between 2009 and 2010.

**Conclusions:** In Maryland, opioid analgesics were frequently implicated in both emergency department and hospital admissions. Opioid poisoning, abuse, and/or dependence accounted for 3.4% of all substance-related hospital admissions, and 0.4% of all substance-related ED visits.

**Implications for Policy, Delivery, or Practice:** Opioid-related intoxications are becoming more common among substance-related diagnosis. As such, it is essential for the state to develop strategies to curb opioid abuse and misuse, and to expand resources for substance abuse monitoring, prevention, and treatment.

**What Is It Like to Be a Young Adult Living with HIV/AIDS in Uganda?**
Pamela Mukaire, Loma Linda University School of Public Health

**Presenter:** Pamela Mukaire, MEd, MPH, Student, Health Promotion & Education, Loma Linda University School of Public Health, pmukaire@llu.edu

**Research Objective:** The study aimed to describe the challenges of young adults living with HIV/AIDS, and to explore recommendations from them for management of HIV infection and prevention of further transmission of the disease.

**Study Design:** Using in-depth interviews, this cross-sectional narrative inquiry was organized around experiences of HIV infection, disclosure, social support, self care, sexuality and transmission prevention. Recruitment utilized flyers and poster at treatment centers and radio announcements in low literacy villages.

**Population Studied:** Nine young adults aged 18 to 24 from three urban and rural districts were interviewed; male and female, with heterosexual and vertically acquired HIV, in school and out of school, single and in unions with HIV negative and positive children, in good and poor health with the most reported health ailments of malaria and cough.

**Principal Findings:** Gender, age, being an orphan, intergeneration adult AIDS death, intergenerational poverty and food insecurity played a decisive role in vulnerability to contracting and spreading HIV/AIDS. Vertical infected youth experienced more debilitating emotional problems to include suicide ideation or attempts, isolation and challenges socializing or envisioning a “normal” future. Horizontally infected youth reported an unwillingness or readiness to disclose status to sexual partners. Some knowingly engaged in
unprotected sex without disclosure, but later proposed and encouraged couple HIV testing to their sexual partners. Almost all parenting youth gave up primary care giving of their infants to their parents and relatives as a measure of reducing the risk of mother-to-child transmission. Some females struggled with the demands of pregnancy and compromised health to meet socio-cultural expectations of child bearing. Youth reported lack of (a) gainful employment; (b) privacy at free antiretroviral treatment facilities as a major barrier to utilization of health services, (c) formalized social support for rural youth leading to increased isolation, hopelessness, and use of sex as a means of economic survival, (d) food and fluid complicating antiretroviral drug adherence, and (e) self-efficacy to consistently negotiate condom use.

**Conclusions:** HIV/AIDS lived experience needs to be conceptualized as a developmental and social process with new emerging roles and identities. A combination of preventive knowledge, socio-economic and food resource programs is essential to meet basic survival needs that significantly influence impoverished youth’s behavior change and health outcomes.

**Implications for Policy, Delivery, or Practice:** HIV treatment and care programs need to integrate the identification of work opportunities, and provision of skills training for income generating opportunities in their preventive care services. Integrate developmentally appropriate multiple supports to address mental health challenges for HIV infected youth and their families. Social, economic, nutritional and psychological support need to be matched to individual needs (single vs. parenting youth, rural vs. urban youth, vertically infected vs. sexually infected youth)

Health professionals need to empower and provide support to improve timely beneficial disclosure and partner notification, and testing and counseling to prevent HIV infection and to increase partner’s timely access to treatment, care and support. ART centers need to routinely screening for and preventing malaria as a dual health burden co-infection in Uganda is important to improve the quality of life of these youth.

**From Roadblocks to Roadmaps: Reimbursement Strategies for Integrated Mental Health Services in Primary Care**

Allison O’Donnell, MPH, VA Ann Arbor Center for Clinical Management Research; Kristina Nord, VA Ann Arbor Center for Clinical Management Research/Department of Psychiatry, University of Michigan; Mark Williams, MD, Integrated Behavioral Health, Mayo Clinic; Amy Kilbourne, PhD, MPH, VA Health Services Research & Development (HSR&D), Quality Enhancement Research Initiative/Department of Psychiatry, University of Michigan

**Presenter:** Kristina Nord, M.S.W., Project Manager, VA Ann Arbor Center for Clinical Management Research/Department of Psychiatry, University of Michigan, kmnord@umich.edu

**Research Objective:** Interventions such as the Chronic Care Model (CCM) have shown to improve both medical and psychiatric outcomes in primary care settings in individuals with mental disorders, but have not been widely implemented. We explore challenges and opportunities for reimbursement under the current fee-for-service system and present a reimbursement roadmap for CCM in primary care settings.

**Study Design:** Review of current literature and regulatory guidelines

**Population Studied:** Health care professionals that provide mental health services in primary care

**Principal Findings:** A key barrier for CCMs not being widely implemented is the lack of a reimbursement model that adequately compensates providers for core CCM components. Furthermore, in primary care, CCMs are uniquely challenged by the financial and administrative fragmentation of physical and mental health care. The fee-for-service model (FFS) lends little opportunity for reimbursement and sustainability of CCM components. Components that require ongoing investment over time such as care management are especially difficult to finance. We discuss how DIAMOND (Depression Improvement Across Minnesota, Offering a New Direction) was initiated in response to these challenges.

**Conclusions:** For CCMs to be sustainable and utilized in the future, bundled reimbursement payment models will need to be negotiated between payers and providers. Initiatives under
health care reform may assist in facilitating the uptake of CCMs through bundled payments that emphasize quality over quantity.

**Implications for Policy, Delivery, or Practice:**
Frontline providers as well as clinical managers should be involved in the process of developing a sustainable CCM reimbursement model in the age of health care reform for sustainable integrated care to occur.

**Hurricane Katrina: Stress, Substance Abuse, and Exercise in Non-Impacted Vulnerable Counties**
Michael Pesko, Weill Cornell Medical College

**Presenter:** Michael Pesko, Ph.D., Instructor Of Public Health, Public Health, Weill Cornell Medical College, mip2037@med.cornell.edu

**Research Objective:** Natural disasters may impact perceptions of risk among individuals living in areas prone to similar catastrophes. This may lead to stress and increased use of healthy and unhealthy stress reduction outlets.

**Study Design:** I use Hurricane Katrina as a natural experiment to study the hurricane’s impact on stress and three stress-reduction outlets, smoking, binge drinking, and exercise, for residents of at-risk communities that were not directly impacted by Hurricane Katrina. Heterogeneity in substance abuse responses by education is explored at an individual level to examine if increases in risk perceptions may have larger impacts for those with less skill in matching subjective and objective risk, or if Hurricane Katrina led to the dissemination of accurate risk information that was previously less known by low-educated individuals. I match geographical and meteorological data of hurricane storm surge and wind damage risks onto data from the Behavioral Risk Factor Surveillance System for years 2004-2006 at the county level. The counties directly impacted by Hurricane Katrina are removed from the analysis, and I confirmed the stability of population trends between treatment groups and the control group of residents residing in areas not impacted by hurricanes.

**Population Studied:** The Behavioral Risk Factor Surveillance System is representative of the United States non-institutionalized adult population.

**Principal Findings:** Using a difference-in-difference analysis, the study demonstrates that following Hurricane Katrina individuals living in counties vulnerable to storm surge experienced increases in stress, smoking, binge drinking, and exercise compared to the control group. Substantial heterogeneity by education is present. Stratified results suggest that low-educated individuals experienced stress increases that were larger than for the full population. Exercise in the population of low-educated individuals increased proportionately to stress, but substance abuse increased by twice as much. Education, rather than income, accounts for these differences. Results are robust to using placebo outcome variables of having health insurance and having a primary physician. Results are also robust to alternative definitions of at-risk areas.

**Conclusions:** These results suggest that Hurricane Katrina increased perceptions of hurricane risks and, in turn, led to increases in stress and the use of stress-reduction outlets. Education plays a role in both tempering increases in stress and in promoting healthy stress reduction outlets in vulnerable areas following natural disasters.

**Implications for Policy, Delivery, or Practice:** Public health officials and medical providers should be aware that sudden changes in risk perception can increase substance abuse, even far away from the disaster. Increased screening for substance abuse may be warranted in the aftermath of large-scale natural disasters. Additionally, greater dissemination of accurate hurricane risk information, particularly to low-educated individuals, before disasters strike may help to prevent sudden changes in risk perception that have harmful secondary consequences.

**Psychiatric Boarding in U.S. Emergency Departments**
Stephen Pitts, Emory University; Marc M. Gautreau MD, MBA, University of Massachusetts Medical School; Frances L. Vaughn Ph.D., Emergency Care Coordination Center, Assistant Secretary for Preparedness and Response

**Presenter:** Stephen Pitts, M.D.,M.P.H., Associate Professor, Emergency Medicine, Emory University, srpitts@emory.edu

**Research Objective:** Although emergency department (ED) boarding of admitted patients is
recognized as the most important cause of ED crowding, it is not known to what extent the historic national decline in psychiatric treatment capacity contributes to this. Nevertheless, reporting of median psychiatric boarding times has become a formal Centers for Medicare and Medicaid Services (CMS) throughput measure (CQM ED-2 NQF 0497). There has been no national accounting of the burden of ED psychiatric care in the last decade, but emergency department crowding continues to grow to the breaking point in many communities. We sought to determine the extent of boarding among psychiatric ED visits nationally.

**Study Design:** We measured association by means of cross-tabulation (Rao and Scott modification for complex sampling) and used survey regression for multi-variable analyses in these serial cross-sectional samples. Trends are given as the regression coefficient on the variable “survey year” taken as a continuous variable.

**Population Studied:** The National Hospital Ambulatory Medical Care Survey (NHAMCS) is a nationally representative annual survey of ED visits. We defined psychiatric visits using a combination of diagnostic and cause-of-injury codes as described in a previous study

**Principal Findings:** During the study interval (2001-2008) there were 6.5 million psychiatric-related ED visits (PREDV) annually, or 5.6 percent of all visits (95% CI 5.4 to 5.8). There was a 1.2% annual increase in the odds of PREDV (p-value 0.051). In multivariable analysis the odds of PREDV was higher among whites, males, age group 25-45, Medicare, Medicaid, uninsured payer status, and urban location; and less likely among blacks, the U.S. South, and privately insured persons. The overall geometric mean length-of-visit was higher for PREDV (199 minutes) than non-PREDV (135 minutes), a difference of 39 percent (95% CI 36 to 42). There was a 2.2 percent annual increase in the length of visit for PREDV, but this did not differ significantly from a 2.6 percent increase in the length of other visits. But the difference in median length-of-visit was much higher for psychiatric visits requiring transfer in urban EDs (323 minutes) than either non-psychiatric transfers (210 minutes) or psychiatric hospitalizations (267 minutes).

**Conclusions:** Although psychiatric visits continue to account for a large proportion of all ED visits nationally, the increasing trend in visits noted before 2000 in a previous publication has abated. Psychiatric boarding is not a unique problem when patients are admitted: they board the same amount of time as non-psychiatric patients. Excessive psychiatric boarding occurs exclusively in patients who are transferred to another facility.

**Implications for Policy, Delivery, or Practice:** Current CMS throughput measures apply to boarding intervals for admitted patients, but our analysis suggests that transfers from hospital EDs to psychiatric facilities may account for much more delay, and should also be included in this throughput measure.

**Perceived Efficacy in Patient-Physician Interactions and Diabetes Control**

Haiyan Qu, University of Alabama at Birmingham; Richard Shewchuk, University of Alabama at Birmingham

**Presenter:** Haiyan Qu, Ph.D., Assistant Professor, Health Services Administration, University of Alabama at Birmingham, hyqu@uab.edu

**Research Objective:** The goal of this study is to identify profiles of confidence in interaction with physicians based on patients’ responses to the 5-item perceived efficacy in patient-physician interactions (PEPPI) scale.

**Study Design:** An interview survey was conducted with patients who were recruited in a community-based peer support program for patients with type 2 diabetes in rural Alabama in 2010. A Model-based cluster analysis was conducted to model the unobserved heterogeneity in confidence based on patterns of patients’ responses to the following five questions: How confident are you in your ability: 1) to know what questions to ask a doctor, 2) to get a doctor to answer all of your questions, 3) to make the most of your visits with your doctors, 4) to get a doctor to take your chief health concern seriously, and 5) to get a doctor to do something about your chief health concern. These items were measured using a 10-point Likert scale (1 = not at all confident to 10 = extremely confident).

**Population Studied:** Patients (n=420) aged from 24 to 89 years with a mean age of 59.6, 75.7% were females, 86.9% were Black, 58.1% achieved, at best, high school education, 68.6% reported annual household income less than $30,000. On average, their HbA1c was 8.0%
and BMI was 36.3kg/m2. About 39.1% patients used insulin therapy.

**Principal Findings:** Respondents were categorized as belonging to one of three classes based on Bayesian posterior probabilities estimates. Class 1, a highly confident class, included 181 patients (43.0%). Patients in this class reported consistently high levels of confidence with all facets of PEPPPI (9.57-9.98). Patients in this class had on average, statistically lower HbA1c (7.5%) than patients in the other classes. Approximately 81% were female and 30% reported annual incomes of $30,000 or more, and 34% patients used insulin therapy.

There were 179 patients (42.7%) assigned to Class 2, a moderately confident class. Patients in this class reported moderately levels of confidence for all indicators of PEPPPI (8.1 to 8.6).

Patients in Class 2 were on average more affluent (38% reported annual incomes of $30,000 or more), and more likely to be male (31%) than patients assigned to the other classes. The average HbA1c was 8.3%.

Sixty patients (14.3%) were assigned to Class 3, a highly unconfident class. In contrast to patients in Class 1, patients in this class reported consistently low levels of confidence for all indicators of PEPPPI (4.02 to 4.98). Patients in this class had on average, higher HbA1c (8.3%), than patients in the highly confident class (Class 1). Patients in Class 3 were on average poorer (only 16% reported annual incomes of $30,000 or more), and more likely to be insulin therapy users (50%) than patients assigned to the other classes.

**Conclusions:** Patients’ perceived efficacy in patient-physician interactions may influence patients communicating effectively with their physicians about diabetes treatment.

**Implications for Policy, Delivery, or Practice:** A significant variation across classes was observed in terms of patient perceptions about confidence in communication with physicians. A patient-centered tailored program needs to be developed for patients with type 2 diabetes to help them improve communication skills with their physicians.

**Health Plans’ Use of Technology to Improve Quality of Behavioral Health Care**

Constance Horgan, Brandeis University; Amity Quinn, Brandeis University; Sharon Reif, Brandeis University; Deborah Garnick, Brandeis University; Elizabeth Merrick, Brandeis University; Dominic Hodgkin, Brandeis University; Maureen Stewart, Brandeis University; Amity Quinn, Brandeis University; Timothy Creedon, Brandeis University

**Presenter:** Amity Quinn, MA, PhD Student, Institute for Behavioral Health, Brandeis University, amity@brandeis.edu

**Research Objective:** Health information technology (HIT) is a strategy that private health plans may use at the system, provider, and patient levels to improve the quality of behavioral health care. Health plans may use HIT in their interactions with managed behavioral health organizations, providers, and patients to collect, manage, and exchange financial and clinical information. One objective of this survey of private health plans is to examine health plans’ HIT policies and activities.

**Study Design:** We present findings from the third round of the Brandeis Health Plan Survey on Alcohol, Drug and Mental Health Services, an in-depth survey of the delivery and management of substance abuse and mental health services in commercial health plans conducted in 2010. Each plan was asked about its top three commercial products. The survey addressed administrative and clinical issues, including how health plans utilize HIT in their interactions with specialty behavioral health care entities, providers, and patients. We conducted univariate and bivariate analyses; data are weighted to present national estimates.

**Population Studied:** The 2010 survey was conducted in 60 market areas. A total of 389 commercial health plans reported on 939 products. The response rate was 89 percent.

**Principal Findings:** Health plans that utilized their own specialty behavioral health organization for delivery and management of behavioral health services were generally more likely to use HIT at the system, provider, and patient levels than health plans that did not use a specialty behavioral health organization and those that used one owned by a separate company. Among health plans that use a specialty behavioral health organization owned by a separate company, 4 percent exchanged claims information with the specialty behavioral health entity using a common data system. Twenty-six percent of products reported providing financial support for electronic health records as a way to attract and retain behavioral health professionals.

The Cost-Effectiveness of Providing Transitional Care Services to Individuals with Suicidal Ideation or Deliberate Self-Harm
John Richardson, Truven Health Analytics; Tami L. Mark, Truven Health Analytics; Richard McKeon, Substance Abuse and Mental Health Services Administration

Presenter: John Richardson, M.P.H., Senior Analyst, Truven Health Analytics, john.richardson@truvehealth.com

Research Objective: In 2009, over 1.3 million people were discharged from U.S. community hospital emergency departments or inpatient settings with diagnoses of deliberate self-harm or suicidal ideation. Less than 50 percent of these patients receive behavioral health treatment within 7 days of discharge from the hospital. The low rate of follow-up is stunning in light of the well-established fact that the period immediately following discharge for a suicide attempt is a time of greatly heightened risk for a subsequent suicide attempt. The goal of this study was to model costs and economic benefits of care transitions for persons at risk for suicide who were admitted to hospitals or emergency rooms, to determine which interventions are most cost effective.

Study Design: We created a model that compares the costs of providing transitional care services and the resulting increase in follow-up treatment to the savings that come from a decrease in readmission rates. We gathered inputs on the annual number of ED visits and hospital discharges where an individual was diagnosed with suicidal ideation or deliberate self-harm using the 2009 Healthcare Cost and Utilization Project (HCUP) Nationwide Emergency Department Sample (NEDS). We used the 2006-2010 Truven Health MarketScan Commercial Claims and Encounters Database and the Truven Health Multi-State Medicaid Database to estimate the baseline rate of follow-up treatment, the cost of follow-up treatment, and the percentage and cost of readmissions.

We estimated the reduction in readmission rates and the effectiveness of transitional care services from the literature. A sensitivity analysis was carried out to identify the inputs that had a large impact on the return on investment calculation. The model is currently being updated with actual cost and effectiveness information from the National Suicide Prevention Lifeline programs.

Population Studied: Individuals with private insurance or Medicaid who had an ED visit or hospital stay related to suicide or self-harm.

Principal Findings: The sensitivity analyses reveal that care transition intervention costs are a key determinant of whether the intervention will result in savings or minimal expenditures, with $93 as the break-even point under our baseline assumptions for Medicaid. Another key model input is the likelihood of readmission. Under baseline assumptions for the Medicaid population, the break-even point occurs when 14% or more of the population is readmitted.

Conclusions: The model suggests that one way to improve the cost effectiveness of care transitions may be to focus on relative low cost care transition models and on patients at highest risk of another suicide attempt.
Implications for Policy, Delivery, or Practice:
In an increasingly constrained fiscal health care environment, using empirical models to demonstrate the most cost-effective ways to reduce suicides by improving care transitions may be critical to more widespread adoption of post-discharge interventions to reduce suicide and readmission costs. Current quality and financing reforms provide an opportunity to enhance the transitions of care for those with suicidal ideation or deliberated self-harm.

Black, White, Green and Gray: Michigan’s Medical Marijuana Policy and the Impacts on Users
Juliette Roddy, University of Michigan, Dearborn; Paul J. Draus, University of Michigan Dearborn

Presenter: Juliette Roddy, Ph.D., Associate Professor, Social Sciences, University of Michigan, Dearborn, jroddy@umich.edu

Research Objective: In March of 2008, Michigan joined 16 other states in allowing for medical use of marijuana. Implementation of the laws allowing for legal use has been erratic and inconsistent across the state, with dispensaries declared illegal businesses in 2011 by the Michigan Supreme Court, and marijuana users in different environments and social groups report varied effects of the law on their use. This research reports the effects of Michigan’s Medical Marijuana laws on urban minority users within the city of Detroit, most consuming illegally.
Study Design: Responses on historical consumption as well as current drug seeking, purchasing and use are reported for 38 (on-going) users using an adapted version of the Marijuana Smoking History Questionnaire (Bonn-Miller and Zvolensky, 2005). Qualitative interviews focus on participants’ self reported assessment of changes in patterns of seeking, purchasing and use following the passage of the medical marijuana laws, including their choice of dealers, availability of different varieties of marijuana, and preferences concerning the places where they buy/use or the people they buy from or use with
Principal Findings: These findings are compared to existing research on legal marijuana purchasing (Aggarwal, in press), heroin purchasing (Roddy and Greenwald, 2009; Roddy, Steinmiller and Greenwald, 2011) and crack (Roddy and Draus, working paper). Illegal marijuana purchasing is quick and local compared to legal purchasing. Less polydrug use, including alcohol, is reported in this sample than in previously reported crack and heroin samples.
Conclusions: The characterization of the urban minority marijuana user has been defined by this sample. The population reports increased access to marijuana, with ‘medical marijuana’ appearing in the street markets. We predict that future research (on-going) will show a marked difference between these illegal urban smokers and the legal white suburban counterparts. The project also has plans to characterize suburban legal minority users and urban majority illegal users.
Implications for Policy, Delivery, or Practice: Michigan’s policy of allowing for medical use without allowing for dispensary purchasing has increased illegal street sales of marijuana. In addition, it has put urban minorities at increased risk for criminal prosecution.

Differences in the Impact of Point of Care Health Assessment across Diverse Primary Care Settings
Hector Rodriguez, UCLA Fielding School of Public Health; Beth A. Glenn, UCLA Fielding School of Public Health; Tanya Olmos, UCLA Fielding School of Public Health; Dylan H. Roby, UCLA Fielding School of Public Health; Roshan Bastani, UCLA Fielding School of Public Health

Presenter: Hector Rodriguez, Ph.D.,M.P.H., Associate Professor, Department of Health Policy and Management, UCLA Fielding School of Public Health, hrod@ucla.edu

Research Objective: Primary care clinicians are challenged with addressing adult patients’ multiple behavioral health issues during 15-minute office visits. The problem may be especially acute in federally-qualified health centers (FQHCs) compared to higher-resource settings. We compare the total number of problem health behaviors and patient reports of clinical discussions across FQHCs, practice-based research network (PBRN) practices, and...
VA primary care practices enrolled in a NIH-funded study.

**Study Design:** Health assessments were administered in 9 primary care practices. The assessment included health behavior and psychological status domains: Perceived Health, Anxiety and Depression, Stress, Sleep Quality, Tobacco Use, Risky Drinking, Substance Use, Diet/Nutrition, Physical Activity. Completed assessments (n=463) were available to clinicians during clinical encounters and clinicians were encouraged to discuss results with patients. Research staff conducted follow-up surveys (n=409) to assess patient-clinician discussions. Using published cutpoints for “positive screens,” we calculated the proportion of respondents who would qualify for primary care intervention for each domain. To examine how problem health behaviors differed by setting (FQHC vs. PBRN vs. VA), we specified multilevel regression models predicting the total number of positive screens per patient. These models accounted for patient-clustering within sites using site random effects and controlled for patient age, sex, marital status, educational attainment, employment, U.S.-nativity. We also examined how each domain differed by setting in adjusted random effects logit models and the extent to which patients’ experiences of the clinician encounter was similar across settings.

**Population Studied:** 463 adult patients receiving non-urgent care during the 1-3 week implementation period.

**Principal Findings:** The median total number of positive screens per patient was similar across FQHCs (3.7-positives, SD=1.8), PBRN practices (3.8-positives, SD=1.9), and the VA clinic (4.1-positives, SD=2.0). The most common problem health behaviors were similarly ranked across settings, but a higher proportion of VA patients reported high-stress, problem alcohol use, smoking, smokeless tobacco use, depression, and drug use compared to FQHC and PBRN patients. FQHC patients were more likely to report “fair” or “poor” health status. In multivariate random effects models accounting for patient sociodemographic characteristics, differences in problem areas between settings were largely attenuated. FQHC patients were more likely to screen positive for low fruit/vegetable consumption (p<0.05) and problem alcohol use (p<0.05). VA patients were more likely to screen positive for high-stress (p<0.05). FQHC patients, however, were less likely to report that their clinician shared results from the assessment (53.7% vs. 67.7%, p<0.05), asked about their concerns with results (46.7% vs. 67.0%, p<0.01), asked which concerns they would like to work on (48.7% vs. 81.3%, p<0.001), helped identify steps to address concerns (64.6 vs. 85.6, p<0.001). There were no differences in the use of the assessment during the clinical encounter between PBRN and VA practices.

**Conclusions:** The sociodemographic profiles of FQHC and VA patients explain most differences in problem health behaviors across settings. FQHC patients were less likely to report that their clinician reviewed results or provided guidance for goal-setting for health behavior change.

**Implications for Policy, Delivery, or Practice:** Facilitating patient-clinician discussions about health behaviors appears to be most challenging in resource-constrained FQHCs, a challenge that will likely intensify as health care reform unfolds.

**Medicare and Medicaid Cost and Utilization for Medicare and Medicaid Enrollees with Schizophrenia**

Michelle Roozeboom, General Dynamics Information Technology; Kathy Schneider, General Dynamics Information Technology

**Presenter:** Michelle Roozeboom, Ph.D., Senior Analytics Manager, General Dynamics Information Technology, michelle.roozeboom@vangent.com

**Research Objective:** Medicare and Medicaid cost and utilization is higher for individuals identified as having a physical or mental health condition, compared to those without any chronic conditions. Linkage of Medicare and Medicaid data allows for accurate evaluation of cost and utilization of dual eligible beneficiaries, and enables comparisons to individuals who only receive Medicare coverage and individuals who only receive Medicaid coverage. Combined Medicare and Medicaid data available in the Medicare Medicaid Linked Enrollee Analytic Data Source (MMLEADS) from the Chronic Condition Data Warehouse (CCW), allows for research of physical and mental health conditions, eligibility, enrollment, cost and utilization for individuals enrolled in either Medicare or Medicaid. MMLEADS is a suite of annual person-level and service-level analytic files designed to serve as a tool for improving...
the care for Medicare and Medicaid enrollees. A Conditions Data File provides information for the 27 CCW conditions, and for nine mental health and tobacco use clinical conditions developed specifically to enhance research of the Medicare-Medicaid population. The MMLEADS files do not contain information for the Medicaid-only non-disabled population (largely consisting of women and children).

The objective was to highlight some key features of this new data product, and use the data to evaluate cost and utilization for Medicare and Medicaid enrolled individuals identified as having schizophrenia compared to individuals without the condition.

**Study Design:** The 2008 MMLEADS was used for identification of individuals with schizophrenia, classification of Medicare-Medicaid enrollment status (MME type), and calculation of cost and utilization statistics. Analyses were limited to individuals identified as either Medicare full fee for service (FFS) or Medicaid FFS based MME type due to limitations of managed care data available in the MMLEADS.

**Population Studied:** The study population consisted of 53,378,728 individuals who were identified as either Medicare only (n=38,888,163), Medicare-Medicaid eligible (n=8,961,728), or Medicaid only with a disability (n=5,529,059).

**Principal Findings:** Approximately twelve percent of the Medicare-Medicaid eligible population is identified as having schizophrenia (11.98%) compared to 9.1% of Medicaid only with a disability, and 1.7% of Medicare only. Per capita payments for individuals with schizophrenia who were enrolled in Medicaid only were $35,390 compared to $17,688 for those without the condition. Medicare-Medicaid eligible individuals with schizophrenia had total per capita payments of $50,549 ($25,246 Medicare and $25,303 Medicaid) compared to $28,471 ($15,326 Medicare and $13,145) for those without the condition; and Medicare only individuals with schizophrenia had Medicare per capita payments of $26,167 compared to $7,615 for those without the condition. Medicare-Medicaid eligible individuals with schizophrenia had 659 hospital admissions per 1,000 beneficiaries compared to 412 for individuals without schizophrenia.

**Conclusions:** The use of the MMLEADS allows for efficient analysis of Medicare and Medicaid cost and utilization for individuals with mental health conditions. These individuals have high cost and utilization compared to individuals with similar eligibility without a mental health condition. A biased understanding of utilization for dually enrolled people is obtained if using only Medicare or only Medicaid data. Examination of high-cost or high-use conditions for Medicare and Medicaid enrollees should consider data from both programs to obtain a complete and accurate assessment.

**Implications for Policy, Delivery, or Practice:** Interventions designed to reconfigure care for people with mental health conditions may reduce hospital admissions and reduce cost.

**Funding Source(s):** CMS

**Poster Session and Number:** B, #609

**The Use of Behavioral Health Quality Measures by State Agencies and Implications for Health Care Reform**

Julie Seibert, Truven Health Analytics

**Presenter:** Julie Seibert, Ph.D., Research Leader, ACRS, Truven Health Analytics, julie.seibert@truvenhealth.com

**Research Objective:** A key feature of the Affordable Care Act is the requirement of a National Quality Strategy to “improve the delivery of health care services, patient health outcomes, and population health.” This three-part aim is of particular importance for individuals who require behavioral health services. However, historically, the quality improvement infrastructure for behavioral health care has been less well developed than that of general health care. This is due, in part, to lack of funding, lack of established clinical databases and lack of relevant standardized quality measurement tools that can be easily adopted and implemented by State agencies. However, due to anticipation of health care reform and the increase in managed behavioral health care, many states are developing and adopting behavioral health care quality measures. This study aims to ascertain what quality measures state agencies funding behavioral health services are using and what measures are agencies adopting that go beyond what is currently required by the National Committee for Quality Assurance (NCQA).

**Study Design:** In order to determine what states are reporting on the quality of behavioral health care, we accessed all of the state mental health agency web sites as cataloged by the National Association of State Mental Health Program Directors Research Institute. We then
looked for quality indicators by searching under sections labeled “reports”, “publications”, “data” or “special projects”. We then searched for state Medicaid managed care contracts, quality strategies, and other quality documents to review. We used the terms “Medicaid managed care contract”, “quality strategy”, and “behavioral health quality indicators” preceded by specific state names. We initially focused on states that were known to have behavioral health Medicaid managed care programs, but subsequently added the remaining states in order to capture indicators that were not specific to managed care.

**Population Studied**: The population studied includes documents publicly provided by state mental health agencies and state Medicaid agencies.

**Principal Findings**: A review of the documents we located on the web showed that many state agencies used the HEDIS measures that were specific to behavioral health and a consumer satisfaction survey. Surveys included the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey, the Mental Health Statistics Improvement Program (MHSIP) Consumer Survey or a locally developed satisfaction survey. Some state agencies supplemented these measures with locally developed measures that relied on administrative data or non-administrative data such as chart review or state-specific databases such as critical incident or client outcomes reporting databases. Major categories of measures relying on administrative data included financial measures, variations on follow-up services, medication adherence, re-admissions and service utilization. Hybrid measures addressed early intervention and screening, medication reviews and treatment and crisis plan reviews.

**Conclusions**:

**Implications for Policy, Delivery, or Practice**: There continues to be a paucity of behavioral health quality measures used by state agencies outside of NCQA measures. There is a need for additional standardized measures that rely on administrative data as well as non-administrative data. There is a particular need for additional substance abuse measures, as Medicaid expansion will potentially increase the number of individuals requiring substance abuse services.

**Social Networks Boost Diabetes Education and Reduce HbA1c and Blood Sugar**

Fadia Shaya, University of Maryland School of Pharmacy; Viktor V. Chirikov, University of Maryland School of Pharmacy; DeLeonardo Howard, University of Maryland School of Pharmacy; Clyde Foster, University of Maryland School of Pharmacy; Soren Snitker, University of Maryland School of Medicine; Julian Costas, Sanofi US; Kathrin Kucharski, Sanofi US; Jeffrey Frimpter, Sanofi US

**Presenter**: Fadia Shaya, Ph.D., M.P.H., Professor; Director Of Research And Outreach Cips, CIPS: Center for Innovative Pharmacy Solutions, University of Maryland School of Pharmacy, fshaya@rx.umaryland.edu

**Research Objective**: The goal of the “Diabetes Peer to Peer (P2P, registered trademark) Study” was to assess the effect of social networks for diabetes information sharing on the improvement of diabetes management in patients with type 2 diabetes in the Baltimore metropolitan area.

**Study Design**: In this prospective cohort study enrolling patients with diabetes, those in the intervention group (P2P) were asked to recruit peers, form small groups, and attend monthly diabetes education sessions, emphasizing peer-support. Patients in the control group were recruited individually to attend standard diabetes education sessions. The primary outcomes were changes in Hemoglobin A1C (HbA1c) and blood glucose. Secondary outcomes included clinical indicators (blood pressure, BMI), functional status, self-efficacy, perceived cohesion, social network connectedness, and diabetes knowledge. Socio-demographics, drug history, and comorbidities were also recorded. Multivariate regression models, finalized after a stepwise selection process, were built to assess mean absolute changes in HbA1c and blood glucose at the first follow-up, at 3 months.

**Population Studied**: Diabetic patients (N=136) recruited from a largely African American population residing in the Baltimore metropolitan area.

**Principal Findings**: Of a total of 136 enrolled, the intervention patients (68) had more metformin use, higher BMI, lower social network scores, and lower diabetes knowledge at baseline. All other baseline characteristics were evenly distributed between arms. At follow-up, P2P patients had a larger reduction in HbA1c (-0.47 vs. -0.31 percent, P=0.17) and blood

Sarah Shih, M.P.H., Executive

Director, Health Care Quality Information and

Evaluation, New York City Department of Health

and Mental Hygiene, sshih@health.nyc.gov

Research Objective: Evaluate patient smoking

status by characteristics of the patient and

cessation interventions.

Study Design: New York City Department of

Health and Mental Hygiene piloted a pay for

improvement program, Health eQuits, to

courage health care providers to increase
	heir delivery of cessation interventions with

patients who smoke. Providers were offered a

small monetary incentive for each additional

cessation intervention above their baseline rate
delivered to patients that were current smokers.

A smoker who quit was defined as one who

went from current to former smoker on a

subsequent visit. Descriptive statistics were

generated from observations across ten

participating practices and chi-square tests were

used to assess significance between groups by

gender, age, race, the types of insurance and

receipt of cessation interventions. Three types of

cessation interventions were included in this

study: only medication (nicotine replacement

therapy, varenicline or bupropion), only

counseling on the benefits of quitting by health

care provider, or both. Multivariate logistic

regression was used to examine the effect of

smoking cessation interventions.

Population Studied: Patient level data were

collected from October 2009 through March

2012 and de-identified from ten Community

Health Centers (CHCs); all settings had adopted

electronic health records, assisted by the

Primary Care Information Project. Data included

patient demographics and information from

office visits (N=334,768). Smoking status for

patients was documented as Current Smoker,

Former Smoker, or Non-Smoker. The study

included patients ages 18 years or older and

with a recorded smoking status (N= 126,725).

Principal Findings: From patients with a

recorded smoking status, 30 percent were

identified as current smokers, 11 percent as

former smokers and, 59 percent as non-

smokers. A total of 36,779 smokers were

available for analysis. Majority of the smokers

had Medicaid insurance (69.9%) and 31.8%

were Hispanic, 44.4% were black race/ethnicity,

and 54.9% were female. Of the current smokers,

65.6% did not receive any cessation

interventions. Those who received cessation

interventions were more likely to be older (ages

35 – 64), of black ethnicity, and with Medicaid

insurance. Counseling only was the most

common treatment mode (57.4%), followed by

both counseling and medication (23.6%), and

medication only (19.0%). Unadjusted quit rates

by treatment were highest for medication only

(8.44%), followed by both medication and

counseling (7.13%), counseling only (5.11%).

After controlling for patient’s characteristics,
types of insurance and the survey answers of

the smart form, the quit rate for smokers with no

intervention was (5.37%). Patients who received

both medication and counseling were more likely
to quit (OR = 1.86, [1.56, 2.22]) than patients

that received only medication (OR=1.73, [1.44,

2.09]) and non-significant for patients with only

receipt of counseling (OR=1.01, [0.89, 1.16]).

Conclusions: Though the program was

successful in increasing the delivery of cessation

intervention to smokers (from 26.2% to 48.5%),

combined medication and counseling

interventions have a more positive effect on quit
children receiving behavioral health services or under the age of 18 using antipsychotics among those enrolled children for whom there are superior, evidence of efficacy, is driven in part by strong evidence of the adverse effects of antipsychotic use, and mounting evidence that children may be at even greater risk for adverse effects from these medications than adults. Prior authorization may be an effective policy mechanism for reducing the rate of use among children for whom there are superior, evidence based treatment modalities. Despite the increasing interest among state Medicaid programs in interventions to influence the use of antipsychotic medication in children, we are unaware of empirical studies that have examined this issue. The findings from this research is needed to understand the extent to which such policies impact different groups of children that vary either clinically or socio-demographically.

Implications for Policy, Delivery, or Practice: The impact of prior authorization policies on antipsychotic medication use varied by age: Among 6-12 year old children, use of antipsychotic medication decreased by approximately 4% (p<0.01) following the prior authorization policy, while no such effect was observed for children 0-5 years or 13-17 years of age.

Conclusions: Prescription policies affecting children’ receipt of antipsychotics may not have a comparable impact on all children. Future research is needed to understand the extent to which such policies impact different groups of children that vary either clinically or socio-demographically.

Implications for Policy, Delivery, or Practice: The impact of prior authorization policies on adult prescribing has been mixed. Policymakers’ concern about the increased use of antipsychotics in children, particularly among children with disorders for which there is limited evidence of efficacy, is driven in part by strong evidence of the adverse effects of antipsychotic use, and mounting evidence that children may be at even greater risk for adverse effects from these medications than adults. Prior authorization may be an effective policy mechanism for reducing the rate of use among children for whom there are superior, evidence based treatment modalities. Despite the increasing interest among state Medicaid programs in interventions to influence the use of antipsychotic medication in children, we are unaware of empirical studies that have examined this issue. The findings from this
Identifying and Assessing Provider Networks Serving High-Need Individuals with Serious Mental Illness: An Innovative Use of Medicaid Claims
Bradley D. Stein, RAND Corporation; Mark Sorbero, University of Pittsburgh Medical Center, CCBHO; Thomas E. Smith, Columbia University College of Physicians & Surgeons; Michael Cham, Blenderhouse; Sheila Donohue, New York State Office of Mental Health; Carole Taylor, Community Care Behavioral Health Organization; Susan M. Essock, Department of Psychiatry, College of Physicians and Surgeons, Columbia University

Presenter: Mark Sorbero, M.S., Director, Healthcare Analytics, Outcomes and Evaluation Research, University of Pittsburgh Medical Center, CCBHO, mark.sorbero@gmail.com

Research Objective: The objective of this research was to identify professional networks among mental health providers, and explore if rates of being “lost to care” for individuals with serious mental illness vary across these networks.

Study Design: Using methods adopted from social network analysis, administrative data from a quality improvement initiative conducted in a large urban center in 2010 were used to examine the care for 14,128 high-need adults with serious mental illness. Distinct networks depicting connections between providers sharing at least 100 of these individuals with another provider were constructed, and rates of individuals shared by providers who were lost to care were assessed.

Population Studied: We studied Medicaid-enrolled individuals age 18 years and older currently receiving or who had previously received court-mandated outpatient mental health treatment or prison-based mental health services, had recently received Assertive Community Treatment, intensive or supportive case management, or had two or more psychiatric emergency room or inpatient hospitalizations in the prior 12 months. These “high-need” individuals were presumed to be in ongoing need of mental health services.

Principal Findings: Five distinct provider networks serving high need individuals with serious mental illness were identified. The number of provider organizations sharing at least 100 individuals in each network varied from 11 provider organizations in the largest network to 5 in the smallest, as did the average number of individuals shared between providers, which ranged from 256 individuals to 149 individuals. None of the networks were dominated by a single provider, and geographic proximity did not appear to be the primary factor in determining involvement in a network. There was substantial variation across networks and type of provider organization in the rate individuals shared by network providers were identified as being lost to care.

Conclusions: Provider networks serving high need individuals with serious mental illness can be identified with administrative data. The variation in patterns of care that can be identified in such provider networks have the potential to serve as the basis for the development of targeted system level interventions to decrease the likelihood of individuals being lost to care.

Implications for Policy, Delivery, or Practice: These analyses identify provider networks serving high-need populations and patterns of disengagement from care among providers within such networks. They provide a potential system-level tool for policy makers and other stakeholders seeking to target intervention efforts to address this public health challenge. In recent years, there have been increasing calls to use existing information to improve the health care delivery system. Social Network Analysis methods, like the ones employed in this study, have already been demonstrated to illustrate common practice patterns and sharing of information among physical health providers, and may be one approach to using administrative data to provide useful information to providers and regulatory officials struggling to manage the high rates of treatment discontinuation and resultant poor outcomes among individuals with mental health disorders.

Providing Medical Care Management in Mental Health Settings: Lessons and Data from the Bangor Beacon Program
Barbara Sorondo, Eastern Maine Medical Center
**Presenter:** Barbara Sorondo, MD, MBA, Director, Clinical Research Center, Eastern Maine Medical Center, bisorondo@emh.org

**Research Objective:** To evaluate the impact of using medical care management that includes electronic text messaging with patients who have a primary mental health/addiction diagnosis, and one of 4 chronic medical problems (diabetes mellitus, asthma, chronic obstructive pulmonary disease, cardiovascular disease).

**Study Design:** Quasi-experimental cohort analysis comparing patients’ baseline health status and self-report measures (medication adherence, disease management self-efficacy, quality of life, satisfaction with treatment) with their status on these same measures at 6 and 12 months after initiation of care management. Changes in healthcare utilization associated with the initiation of care management was evaluated by comparing the number of emergency/urgent care visits and the number of hospitalizations in the 6 months prior to care management with the number at 6 months post care management.

**Population Studied:** All mental health clients older than 18 years of age, with one of the following concomitant conditions: diabetes mellitus, COPD, CHF or asthma, who agreed to receive medical care management were invited to participate in the study.

**Principal Findings:** Outcome measures collected in this project generally suggested that clients receiving medical care management through their mental health treatment agency improved in the 12 months following enrollment. Improvements in health measures such as blood pressure, LDL cholesterol, and HbA1C were modest but in the desired direction. The most significant improvements were seen in patients’ self-report of perceived health status, medication adherence, and self-efficacy of disease management. The fact that patients perceived themselves as having improved is important in its own right. It may also be that perceived improvement in chronic illness self-management is the first step towards improvement in more biologically based measures of health.

**Conclusions:** This paper summarizes the experience of implementing a medical care management model for people with both a severe mental illness and a chronic health problem.

**Implications for Policy, Delivery, or Practice:** Future efforts to develop medical care management models for mental health patients with chronic illnesses might focus on enhancing tools for identifying and tracking patient groups with targeted chronic disease as part of existing electronic health record systems. Identifying and studying the effectiveness of strategies to enhance client engagement in health management is another area in need of attention. For example, electronic communication strategies for building relationships and improving treatment adherence such as texting treatment reminders or web-based video interactions, may offer cost effective ways to support clients in improving their health status. Study of optimal client:staff ratios for effective medical care management will also be an important and ongoing issue.

**Integrating Behavioral Health Care into the Patient-Centered Medical Home**

Judith Steinberg, University of Massachusetts Medical School; Megan Burns, M.P.P., Bailit Health Purchasing, LLC; Michael Bailitt, M.B.A., Bailit Health Purchasing, LLC; F. Alexander Blount, EdD, Center for Integrated Primary Care, University of Massachusetts Medical School

**Presenter:** Judith Steinberg, M.D., M.P.H., Deputy Chief Medical Officer, Commonwealth Medicine, University of Massachusetts Medical School, judith.steinberg@umassmed.edu

**Research Objective:** To design an innovative approach to assist primary care practices that are transforming into PCMHs with behavioral health integration through the creation of a practice self-assessment tool and a toolkit for implementation of behavioral health integration elements. The MA PCMH Initiative (MA PCMH) is a statewide, three-year, multi-payer demonstration of PCMH implementation in 45 primary care practices. MA has emphasized the integration of behavioral health and primary care (integrated care) in its PCMH model. Participating practices receive technical assistance in the implementation of integrated care and their progress towards implementation is measured.

**Study Design:** Practice self-assessment of their status of implementation of 39 identified behavioral health integration elements. A set of 39 elements of care integration was developed, starting with previous work by Mountainview
Consulting and organized within 5 domains: (1) Relationship Care and Communication Practices, (2) Patient Care and Population Impact, (3) Community Integration, (4) Care Management, and (5) Clinic System Integration. The elements of integration were translated into a practice self-assessment survey by assigning a scale of integration for each element. Typically, the scale ranged from “rarely” accomplish the particular element of integration to “routinely”. The self-assessment tool was administered using Survey Monkey to the 45 practices in March 2012, as a baseline assessment. Practices were instructed to have the primary care team complete the survey in conjunction with the behavioral health provider with whom they work. Results were compiled and analyzed across all respondents. An online toolkit to support practices’ implementation of each element was developed.

**Population Studied:** The 45 MA PCMH primary care practices include community health centers, large and small private practices and academic medical practices.

**Principal Findings:** The response rate was 96%. Fifty-two percent of responding practices completed the survey as a team. Selected results include: 16% of respondents routinely incorporate smooth hand-offs between primary care and behavioral health providers; 35% routinely screen patients for alcohol use and depression; 70% routinely or sometimes provide referrals to self-help supports in the community; 9% routinely have effectively coordinated integrated treatment plans; and 33% provide same day access for behavioral health visits.

**Conclusions:** This baseline practices self – assessment of integrated care has identified several areas for improvement that inform our technical assistance to the practices and which the practices can use to focus their implementation efforts. The online behavioral health integration toolkit, which provides concrete steps to implementation of the integration elements and links to practice tools, such as templates for integrated care plans, can be a resource to practices. Measurement of progress towards achieving behavioral health integration will be assessed through interval re-administration of the self-assessment tool and through clinical quality measures of integration.

**Implications for Policy, Delivery, or Practice:** Integration of primary care and behavioral health is an important component of PCMHs. Practices need support in implementing integration elements and a method to assess their implementation progress.

**Using Financial Incentives to Improve Quality of Behavioral Health Care: National Findings on Private Health Plans**

Maureen Stewart, Brandeis University; Constance M. Horgan, ScD, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University; Dominic Hodgkin, PhD, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University; Sharon Reif, PhD, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University; Deborah Garnick, ScD, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University; Elizabeth Merrick, PhD, MSW, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University; Amity Quinn, Institute for Behavioral Health, Heller School for Social Policy and Management, Brandeis University

**Presenter:** Maureen Stewart, Ph.D., Senior Research Associate, Heller School for Social Policy and Management, Brandeis University, mstewart@brandeis.edu

**Research Objective:** As private health plans work to ensure delivery of high value care, the design of payment approaches and financial incentives are tools they can use to improve quality of care and member health. Payments can be designed to provide positive or negative incentives and may be directed at a number of levels including: provider organizations, individual providers, other specialty behavioral health vendors, or health plan members. One objective of this survey of private health plans is to identify payment techniques currently used in behavioral health and examine associated health plan characteristics.

**Study Design:** We present findings from the third round of the Brandeis Health Plan Survey on Alcohol, Drug and Mental Health Services, an in-depth survey of the delivery and management of substance abuse and mental health services in commercial health plans. The telephone survey of executive and medical directors addressed a variety of issues including administrative characteristics of the health plan, provider payment, and use of incentives. We
Prevalence of Mental Illness among VA Primary Care Patients and Relationship to Clinical Outcomes
Ranak Trivedi, University of Washington/VA Puget Sound

Presenter: Ranak Trivedi, Ph.D., Research Assistant Professor/Core Investigator, Department of Health Services/HSR&D Center of Excellence, University of Washington/VA Puget Sound, ranak.trivedi@va.gov

Research Objective: To estimate the prevalence of common mental illnesses among Veterans seen within VA primary care, and examine their associations with patient outcomes.

Study Design: 1-year prospective study

Population Studied: We examined the VA’s corporate data warehouse to identify all Veterans who made at least one face-to-face to a primary care provider during the year prior to implementation of the patient centered medical home model, the Patient Aligned Care Team (PACT). We determined the prevalence and co-occurrence of 5 common psychiatric conditions: depression, post-traumatic stress disorder (PTSD), substance use disorders (SUD), anxiety, and serious mental illness (SMI). SMI consisted of bipolar disorder and schizophrenia.

We considered a Veteran to have a diagnosis of depression, PTSD, anxiety, or SMI if he or she had ≥2 outpatient or ≥1 inpatient diagnosis of the relevant ICD9 codes. A patient was deemed to have SUD if there was ≥1 inpatient or outpatient diagnosis based on ICD9 codes. Multivariate regression models were used to assess associations between presence of psychiatric conditions hospitalization or death during the subsequent year. Covariates included age, co-morbidity, sex, race, visits in primary care mental health integration, and specialty mental health care visits.

Principal Findings: Of 5,169,380 Veterans included, 58% were White, 94% were male, and 59% were married. The prevalence of the 5 mental conditions was: depression (12%), PTSD (8%), SUD (5%), anxiety (4%), and SMI (3%). 29% were diagnosed with 1 of these 5 mental illnesses. 14% had 2 mental illnesses and 3.65% had 3 illnesses. The most common co-occurring mental illnesses were depression and PTSD (3%). Among Veterans with depression, 31% also had PTSD and 17% had SUD. Among Veterans with SMI, 28% also had depression,

Conclusions: Positive financial incentives are commonly used by health plans, but often do not apply to behavioral health conditions. While financial penalties are included in contracts with managed behavioral health organizations, almost no plans report financial penalties for providers or provider organizations.

Implications for Policy, Delivery, or Practice: Payment approaches and associated incentives are key tools for health plans to use to drive delivery of quality care. Financial incentives are not often targeted to specific behavioral health conditions; more attention to these conditions may result in improved quality of care.

Funding Source(s): NIH
23% had SUD and 21% had PTSD. Chronic medical problems were also common among Veterans with mental illness including diabetes (25%), hypertension (50%) and ischemic heart disease (17%). Hospitalizations within 1 year ranged from 14% for patients with PTSD to 24% for those with SUD. One-year mortality ranged from approximately 2% (PTSD) to 3.5% (SUD). After adjustment for covariates, all categories of mental illnesses were associated with greater likelihood of 1 year hospitalizations: PTSD (OR=1.05; 95%CI=1.03, 1.06), depression (OR=1.65; 95%CI=1.63, 1.68), SMI (OR=2.19; 95%CI=2.15, 2.24), anxiety (OR=1.31; 95%CI=1.29, 1.33), and SUD (OR=2.25; 95%CI=2.22, 2.30). PTSD was associated with lower likelihood of mortality within 1 year (OR=.79; 95%CI=.77-.82) whereas depression (OR=1.24; 95%CI=1.21, 1.27), SMI (OR=1.51; 95%CI=1.46, 1.57), anxiety (OR=1.07; 95%CI=1.04, 1.10) and SUD (OR=1.88; 95%CI=1.83, 1.92) were associated with higher odds of death within 1 year.

Conclusions: Mental health conditions are common among Veterans receiving primary care and frequently co-occur. Presence of any of these conditions was associated with a higher risk for hospitalization and all except PTSD was associated with higher risk of mortality.

Implications for Policy, Delivery, or Practice: Primary care is often the first opportunity to treat patients with common mental illnesses. Their association with clinical endpoints such as mortality and hospitalizations provides impetus to integrate psychiatric care within PACT.

Trends in Buprenorphine and Methadone Sales and Utilization in the United States, 1997-2012

Lydia Turner, Johns Hopkins School of Public Health; Stefan P. Kruszewski, MD, Stefan P. Kruszewski, MD & Associates; Ramin Mojtabai, MD, PhD, Department of Mental Health, Bloomberg School of Public Health; Daniel Webster, ScD, MPH, Department of Health Policy and Management, Johns Hopkins Bloomberg School of Public Health; Suzanne Nesbit, PharmD, Department of Pharmacy, Johns Hopkins Hospital; Randall Stafford, MD, PhD, Stanford University, Program on Prevention Outcomes and Practices; G. Caleb Alexander, MD, MS, Department of Epidemiology, Bloomberg School of Public Health

Research Objective: To characterize trends in ambulatory use and sales of buprenorphine and methadone in the United States.

Study Design: Cross-sectional analyses of buprenorphine and methadone utilization and sales using data from the IMS Health National Disease and Therapeutic Index, a nationally representative survey of ambulatory care (1997-2012), the IMS Health National Prescription Audit, reflecting retail, long-term care and mail-order pharmacy sales (2007-2011), and the IMS Health National Sales Perspective, capturing distribution of products from manufacturers to suppliers (2007-2011).

Population Studied: We used three prescription audits to determine the ambulatory use and sales of buprenorphine and methadone. (1) The IMS Health National Disease and Therapeutic Index provides nationally representative estimates of office-based, patient-care physicians through a two-stage stratified sampling method and samples approximately 4,800 physicians each calendar quarter. (2) The IMS Health National Prescription Audit is an industry standard source of national prescription dispensing activity for all pharmaceutical products. (3) The IMS Health National Sales Perspective, capturing distribution of products from manufacturers to suppliers (2007-2011).

Principal Findings: Between 2003 and 2011, there was a sharp increase in buprenorphine ambulatory treatment visits, with an annual rate of increase of approximately 37%, reaching nearly 2 million treatment visits during 2011. During this period, the proportion of buprenorphine treatment visits accounted for by psychiatrists decreased from 92% to 37%. Two-thirds of 2011 treatment visits were for individuals 20-39 years of age, while 91% of these visits were for drug abuse or dependence and 90% involved the use of combination buprenorphine/naloxone (Suboxone) rather than other buprenorphine products. Between January 2007 and December 2011, there were modest increases in retail pharmacy prescriptions for methadone, from approximately 325 to 375 thousand monthly prescriptions. By contrast, buprenorphine sales increased by an average of 40% annually during this period, from
approximately 0.5 million during the first quarter of 2007 to 2.7 million during the last quarter of 2011. Despite these increases, methadone sales from manufacturers to distributors remained generally steady and four-fold greater than buprenorphine sales.

**Conclusions:** Since 2003, there has been a large increase in buprenorphine utilization. While the impact of increases in buprenorphine use on the epidemic of prescription opioid abuse remains to be examined, the increases reflect a substantial shift in the landscape of opioid dependence treatment.

**Implications for Policy, Delivery, or Practice:** In response to a growing epidemic of opioid abuse, an increasing number of individuals require care for opioid dependence. Historically, methadone has been the mainstay of such treatment. We document rapid increases in buprenorphine sales and ambulatory utilization during the past decade. Important questions remain regarding buprenorphine’s real-world treatment effectiveness, cost-effectiveness, patterns of abuse and misuse, and evolving role in the treatment of opioid dependence.

**Poster Session and Number:** B, #619

**Primary Care Internet-Based Interventions to Prevent Adolescent Depression in Randomized Clinical Trials**

Tracy Gladstone, PhD, Wellesley College; Benjamin Van Voorhees, University of Illinois at Chicago; Monika Marko-Holguin, University of Illinois at Chicago

**Presenter:** Benjamin Van Voorhees, M.D., M.P.H., Associate Professor, Pediatrics, University of Illinois at Chicago, bvanvoor@uic.edu

**Research Objective:** Internet-based interventions for youth depression hold promise, but further research is needed to explore the acceptability of these approaches, and ways of integrating emerging technologies for behavioral health within the primary care system. In addition, research is needed to determine how best to access at-risk adolescents from hard-to-reach populations.

**Study Design:** We developed a primary care Internet-based depression prevention intervention, CATCH-IT, to address these needs and are conducting a randomized clinical trial comparing CATCH-IT to a general health education Internet intervention. CATCH-IT was developed utilizing the media theory of "Synchronization of the Senses" to incorporate character stories, peer videos and design/picture elements to create a unified experience meeting today’s social media standards. The intervention also includes an Internet-based parent program incorporating psycho-educational material about youth depression and role-playing video vignettes. A primary care physician motivational interview is used to engage youth and parents with the CATCH-IT program. The Health Education model was developed based on the current well-child curriculum used for primary care visits. We are fielding the interventions in a two-site trial sponsored by the National Institute of Mental Health.

**Population Studied:** The current study targets 13-17 year-olds who are recruited from routine visits to primary care clinics in both urban and suburban settings. All adolescents visiting the clinics are screened for future risk of depressive episodes and, if at-risk, offered enrollment in the trial.

**Principal Findings:** We enrolled N=34 adolescents/expected 400 and N=34 parents/expected in the PATH study, from a total of N=9 practice sites in N=4 major health systems. Adolescents were primarily African American (N=18), and N=10 self-identified as Hispanic. A total of N=102 adolescents participated in a phone screen based on self-reported depressive symptoms, from which 34 were found eligible for enrollment. Overall, practices identified potentially eligible subjects by screening an estimated 24% of adolescents visiting the doctor, and an estimated 12% of adolescents were enrolled. The mean number of modules started or completed was 2.72/14 (SD=3.64) for adolescents and N=1.9/5 (SD=2.05) for parents. Both adolescents and parents noted the availability of character stories, self-diary peer videos and incentives for participation as the most attractive components. Practices noted challenges in economic concerns (N=2 closed), HIPPA compliance requirements, work flow, importance of compensation comparable to private insurance contracts, scheduling, and time required to perform screening.

**Conclusions:** Cultural adaptation and media theory, combined with indirect peer-based interactions, appeared to strengthen participation and engagement by adolescents and parents. In addition, embedding this new technology within the primary care setting may have increased access to hard-to-reach populations.
implications for policy, delivery, or practice: Internet-based interventions must meet today’s social media standards in order to engage adolescents and parents. Close collaboration with primary care practices is required in order to address challenges in implementation.

Preliminary Evaluation of a Novel Suicidal Alert Response System within an Automated Telephonic Assessment and Monitoring System for Depression Care Management

Irene Vidyanti, University of Southern California; Shinyi Wu, University of Southern California; Pai Liu, University of Southern California; Caitlin Hawkins, University of Southern California; Magaly Ramirez, University of Southern California; Jeffrey Guterman, Los Angeles County Department of Health Services; Kathleen Ell, University of Southern California

Research Objective: A novel suicidal alert system was developed for use within an automated depression telephonic assessment and monitoring system. Preliminary evaluation of the performance of the suicidal alert system in its first year of implementation was conducted. The alert system is triggered if a patient responded to the last item of the Patient Health Questionnaire (PHQ)-9 with a score higher than one during an automated telephone assessment (ATA) call (i.e. patient had high intention of self-harm). Three physicians were dedicated to respond to the alerts in a predetermined order. When the alert system was triggered, the system immediately sent a text message and an e-mail to the first responder. If the system did not receive the acknowledgement from the first alerted responder within 15 minutes, the second responder would be alerted. This waterfall fashion alert system continued until a physician took responsibility for the call. The physician was then expected to call the patient and assess his/her status.

Study Design: To evaluate the suicidal alert system, we collated all triggered suicide intention alerts, along with the timestamps of the time the call was completed and the alert was responded to. We then analyzed the alert response time (i.e. the elapsed time between each completed call that triggered the suicidal alert and its response from the provider).

Population Studied: The system was tested on 444 patients in three safety-net clinics contained within the Los Angeles County Department of Health System (LAC-DHS) which made up one arm of a three arm depression care management study. Patients were 18 years or older with diabetes and received primary care in any one of these three sites.

Principal Findings: There were 25 suicide intention alerts out of 2189 calls (1224 calls with completed PHQ) over the period of 10/27/2011 – 9/21/2012. The average response time of 32 minutes was within our target response time of 75 minutes (comprising alert polling interval of 30 minutes and three layers of waterfall at 15 minutes per layer). The maximum alert response time was 2 hours and 4 minutes, which still fell within an acceptable response time range. All patients with alerts were responded to in a timely manner, and none of the patients were assessed to be at high risk for self-harm by the responding providers.

Conclusions: Our finding that all the suicidality alert response times fall within an acceptable range show the promise of our novel suicidality alert response system in helping ensure patient safety within an automatic depression screening and monitoring system.

Implications for Policy, Delivery, or Practice: This suicidal alert system addressed urgent care needs and allowed providers to immediately address patient issues. It is an important safety feature that should be implemented within an automatic depression screening and monitoring system. The suicidal alert system, along with the automated depression screening and monitoring system, acts as a useful complement to provider-based depression screening. By shifting the burden of part of the screening and monitoring away from time-pressured providers, the system has the potential to facilitate more timely depression identification and treatment, particularly in resource-constrained settings such as safety-net clinics.

CHILD HEALTH

Nationwide Emergency Department Visits by Children for Dental Conditions, 2009
Arif Ahmed, University of Missouri-Kansas City; Lakshmi Venkitachalam, MPH, PhD, University of Missouri - Kansas City; Felicity Pino, MS, University of Missouri - Kansas City; Mary M. Gerkovich, PhD, University of Missouri - Kansas City; William E. Lafferty, MD, University of Missouri - Kansas City

Presenter: Arif Ahmed, BDS, PhD, MSPH, Associate Professor Of Health Administration, Public Affairs, University of Missouri-Kansas City, ahmedar@umkc.edu

Research Objective: Despite improvements in coverage and utilization, dental care remains one of the most frequent unmet health care needs of children in the United States. Access to dental care is difficult for many children, particularly those on public financing programs. The hospital emergency departments (ED) nationwide have become the entry point to the health care system for a large number of individuals seeking care for issues that are preventable and/or can be addressed more efficiently at other care delivery venues. A large majority of ED visits for dental complaints are of such nature and the underlying issues are typically not resolved by the services provided at the ED. The objectives of this study were to create a national estimate of ED visits by children for dental complaints and to describe the characteristics associated with those visits.

Study Design: Visit-level data of ED visits for dental complaints by patients 0-19 years of age were extracted from the Nationwide Emergency Department Sample (NEDS) 2009 dataset. First listed diagnoses within the ICD-9-CM codes range 520.0 - 523.9 were used to identify such visits. Sample weights were applied to create national estimates by age group, expected primary payer, location of the patient’s residence, and type of ED event.

Population Studied: The NEDS is a stratified sample of hospital emergency departments in community, non-rehabilitation hospitals in the United States. The 2009 NEDS includes almost 29 million ED visits from 964 hospital-based EDs in 29 states. Approximately 83.8 million individuals 0-19 years of age constituted 27.3% of the US population in 2009.

Principal Findings: Visits by patients 0-19 years of age constituted 10.26% of the estimated 867,968 ED visits for dental conditions nationwide at a rate of 106 visits per 100,000 population. Of these patients, 95.73% were treated and released at the ED. Female patients visited the ED at a higher rate (114/100,000 population) compared to male patients (99/100,000 population). For both sexes, the greatest proportions of visits were by patients ages 16-19 years followed by less than 6 years. The primary expected source of payment for 54% of the visits was Medicaid. Greatest proportions of visits were by patients living in large central metropolitan areas (27.2%) and neighborhoods with median annual income below $40,000 (40.21%).

Conclusions: The poor and vulnerable children seek dental care at the hospital ED at disproportionately higher rates compared to other children. While no direct conclusion can be drawn from this study, the findings corroborate those of other state and regional studies and lend evidence that despite various mitigation efforts, access to dental care for children on Medicaid continues to be problematic nationwide.

Implications for Policy, Delivery, or Practice: Access to preventive and routine dental care for children, particularly those on Medicaid, needs improvement. States’ efforts to increase Medicaid reimbursement for providers at conventional dental care settings should be supplemented by exploration of alternative settings and workforce for delivering preventive and treatment services and oral health education to the vulnerable population.

Priority Mental Health Diagnoses for Quality Measurement in the Inpatient and Emergency Department Settings Nationally
Naomi Bardach, University of California, San Francisco; Tumaini R. Coker, MD MBA, University of California Los Angeles; Bonnie T. Zima, MD MPH, University of California Los Angeles; Anne L. Lynn, MPP, Minnesota Department of Human Services; J. Michael Murphy, EdD, Massachusetts General Hospital; Penelope K. Knapp, MD, University of California Davis; Justine G. Nelson, PhD, Minnesota Department of Human Services; Rita Mangione-Smith, MD MPH, Seattle Children’s Hospital

Presenter: Naomi Bardach, M.D., M.A.S., Assistant Professor, General Pediatrics,
University of California, San Francisco, bardachn@peds.ucsf.edu

**Research Objective:** There is a national call for robust pediatric quality measures in the inpatient and emergency department (ED) settings. Mental health is a key priority with 5% of all pediatric ED visits having a mental health diagnosis and of these, 15% leading to admission. National quality measures should focus on the most common and costly conditions; however, no published studies have examined this for pediatric mental health. Our objective was to use national data to rank pediatric mental health conditions in the inpatient and ED settings by frequency, and to examine how rankings vary by patient characteristics, hospital type, and resource utilization.

**Study Design:** Cross-sectional.

**Population Studied:** We analyzed discharges from a nationally representative database of pediatric hospitalizations (the Kid Inpatient Database from the Agency for Healthcare Research and Quality’s HealthCare Utilization Project 2009 [KID]) and a database from 40 freestanding children’s hospitals nationally (the Pediatric Health Information System 2010 [PHIS]). We examined the relative frequency of 17 ICD9-defined mental health diagnostic groupings in each database, stratifying by inpatient vs. ED, primary vs. secondary diagnosis, and gender. Frequency ranking was according to proportion of all mental health visits in each database. Resource utilization ranking was done in KID according to aggregate annual charges.

**Principal Findings:** Depression was the most frequent primary psychiatric diagnosis in both inpatient and ED settings. In the PHIS ED, the top primary diagnoses were depression (29.0%), externalizing behavior disorders (22.4%), miscellaneous disorders (11.3%), and anxiety (9.1%). The most frequent primary inpatient diagnosis in hospitals nationally and in freestanding children’s hospitals was depression (44.1% [KID] and 47.5% [PHIS]) of mental health discharges). In KID, the next ranking primary diagnoses were bipolar disorder (18.1%), psychosis (12.1%), and externalizing behavior disorders (6.2%). In PHIS, the next ranking primary diagnoses were externalizing behavior disorders (11.7%), bipolar disorder (9.9%), and anxiety disorder (6.5%). When all diagnoses were included (primary or secondary) in KID, substance abuse was the third ranking diagnosis (12.4%). The most frequent primary diagnosis, depression, did not vary by gender, but other top ranking psychiatric diagnoses did. The most frequent primary diagnoses by gender were: For girls and boys in KID, depression (girls: 51.2% and boys: 37.6%), bipolar disorder (18.2% and 17.7%), and anxiety (8.0% and 15.9%). For girls in PHIS, depression (51.4%), eating disorders (10.2%), bipolar (9.1%), and anxiety (8.3%). For boys in PHIS, depression (43.4%), externalizing disorder (16.7%), and bipolar disorder (10.8%). Estimated aggregate annual charges for the most common psychiatric diagnoses were substantial: For depression (n=100,988): $1.364 billion, mean/visit= $13,917). For bipolar disorder (n=41,345): $717 million, mean/visit $16,994). For psychosis (n=27,589): $551 million, mean/visit $19,606).

**Conclusions:** Diagnoses for pediatric mental health quality measurement can be prioritized according to frequency of occurrence and resource utilization.

**Implications for Policy, Delivery, or Practice:** Pediatric priority diagnoses in the inpatient setting are depression, bipolar disorder and psychosis; in the ED they are depression, externalizing disorders, and anxiety. Substance abuse is also a high-priority diagnosis, as a common comorbid condition. Including anxiety and externalizing behavior disorders will address important conditions for girls and boys, respectively.

**Funding Source(s):** AHRQ

**Poster Session and Number:** A, #150

**Perinatal Home Visiting Program Positively Impacts Breast Feeding and Parenting:**

**Findings from the Best Start LA Evaluation**
Sarah Benatar, Urban Institute; Ian Hill, The Urban Institute; Heather Sandstron, The Urban Institute

**Presenter:** Sarah Benatar, Ph.D., Research Associate, Health Policy Center, Urban Institute, sbenatar@urban.org

**Research Objective:** To analyze the impacts of a locally designed home visiting model (Welcome Baby!) for pregnant women and mothers of infants launched as part of a larger community investment project in downtown Los Angeles called Best Start LA (BSLA).

**Study Design:** A six-year evaluation that employs mixed methods to assess program implementation and outcomes; this presentation
primarily focuses on results derived from the longitudinal in-home survey component designed to compare child and family outcomes at 12, 24 and 36 months of age. We survey mothers who received Welcome Baby! home visiting services and also a comparison group of mothers who did not receive Welcome Baby! but live in the pilot community. Families participate in a 90-minute survey and home observation at each wave. In addition, we conducted annual case studies of implementation to document the progress of the overall BSLA investment—and Welcome Baby! specifically—through interviews with home visiting staff, as well as focus groups with Welcome Baby! participants and graduates. **Population Studied:** The child and family survey sample includes 734 low-income mothers and their infants. Approximately 90 percent of mothers are Latino, 70 percent are immigrants, and only half have at least a high school diploma. Annual case study interviews with approximately 12 Welcome Baby! administrators and home visitors and two rounds of focus groups with more than 40 Welcome Baby! participants were also conducted. **Principal Findings:** In-depth case studies have documented the implementation of the Welcome Baby! model. During the program’s first three years, roughly 2,000 parents of newborns received home visits from nurses and college educated “parent coaches” designed to promote breastfeeding, child health and development, effective parenting, home safety, and use of community resources. Visits occur prenatally, at 72 hours postpartum, two weeks, one month (phone call), three months, and nine months. This home visiting model has been altered slightly since it was first launched in response to early case study findings. Focus groups with parents and home visitors find that mothers place high value on the Welcome Baby! service, form strong bonds with home visitors, and perceive improved breastfeeding and parenting. Notably, parents and home visitors assert that the program’s medium-intensity model falls short of meeting the needs of high-risk mothers. Findings from the 12-month wave of the in-home survey indicate that home visiting recipients have a higher likelihood of exclusive breastfeeding, more sensitive parenting behaviors, and more stimulating home environments than the comparison group. **Conclusions:** Welcome Baby! has had a positive effect on families in the pilot community. Small changes designed to be more responsive to the needs of the community have improved the program. **Implications for Policy, Delivery, or Practice:** Home visiting can be a critical component of perinatal care, providing valued maternal support and education, links to other supportive services, and reinforcing critical health behaviors such as breastfeeding, immunizations, nutrition, appropriate child development, effective parenting, and home safety. Subsequent waves of the survey will track longer-term nutrition impacts, child health and development, and school readiness. Evaluation results will inform the implementation of this home visiting program in 13 additional communities across Los Angeles County. **Funding Source(s):** Other, First 5 LA **Poster Session and Number:** A, #151

**Examining the Spread of the School-Based Health Center Concept within the United States**

Brian Bruen, George Washington University

**Presenter:** Brian Bruen, MS, Lead Research Scientist & Lecturer, Department of Health Policy, George Washington University, bkbruen@gwu.edu

**Research Objective:** The objective of this research is to describe how the school-based health center (SBHC) concept expanded from humble beginnings in a handful of diffuse localities to approximately 2,000 locations spread across broad swaths of the country. SBHCs primarily serve low-income, minority and other at risk children in school settings, providing a variety of preventive ambulatory care services and health education. **Study Design:** This study is a case study of existing research focused on social and political factors that contributed to the expansion of the number of school-based health centers in the United States. It is based on a review of the literature about the creation and diffusion of the SBHC concept. It is supplemented by case study interviews with experts, state officials and SBHC providers about the factors that contributed to the successful expansion of this relatively hidden health care system. **Population Studied:** This paper focuses on school-based health centers and the patients/communities that they serve. **Principal Findings:** The number of SBHCs in the United States increased from roughly 100 centers in the early 1990s to more than 1,900...
centers today. The factors described the paper reflect a number of different social, financial and political influences on the development of the SBHC model and its expansion into new locations. For example, early support from the Robert Wood Johnson Foundation helped to solidify the SBHC model and attract attention and financial support, including Medicaid funding. Proponents built support for the movement by defusing—and often accommodating—their opponents, and securing political and financial support. There are many parallels to theories and empirical research from other fields such as political science and public policy in this story, all of which offer insights into why the SBHC movement continues to achieve success despite its small size and politically weak target populations.

Conclusions: Continued expansion requires SBHCs and their supporters to continue to focus on the strengths of existing centers, which include building support from the community and key policymakers, improving measurement of impacts and highlighting success stories to secure more political and financial support, and sharing educational materials and technical assistance to promote further development and innovation.

Implications for Policy, Delivery, or Practice: See conclusions.

Measuring Autism Spectrum Disorder Severity and its Influence on Children's Health Services: A Structural Equation Modeling Approach

Adam Carle, Cincinnati Children's Hospital Medical Center

Presenter: Adam Carle, Ph.D.,M.A., Assistant Professor of Pediatrics, University of Cincinnati School of Medicine, Cincinnati Children’s Hospital Medical Center, adam.carle@cchmc.org

Research Objective: Autism Spectrum Disorder’s (ASD) prevalence and incidence has increased dramatically. This has led to increased research efforts to understand ASD’s impact on these children and their families. Among other things, researchers have begun to examine the relationship between disease severity and the condition’s impact on the family. To this end the National Center for Health Statistics recently conducted the first ever Pathways to Diagnosis and Services survey, a nationally representative survey of children with ASD, intellectual disability (ID), and developmental delay (DD). The survey included numerous questions about children and their families’ experiences, as well as a new scale designed to measure children’s ASD severity. However, to date, no research has addressed how best to use the scale’s items to measure ASD severity (i.e., should investigators create a single severity score or multiple subscale scores?), nor has research examined whether severity predicts children’s outcomes using this scale and data. To address this, I used structural equation modeling (SEM) to simultaneously develop a valid measurement model for the scale and examine the relationship between the construct(s) measured by the scale and the extent to which the severity construct(s) measured by the scale predict a condition’s financial impact on the family and the number of hours caregivers spent arranging care.

Study Design: I used SEM and cross-sectional data from the 2011 Pathways to Diagnosis and Services survey. Pathways, a follow-up to the 2009-2010 National Survey of Children with Special Health Care Needs (NS-CSHCN), is a nationally representative survey of CSHCN 6-17 years old who have ever been diagnosed with ASD, ID, or DD. Among other things, parents answered questions about severity and the condition’s impact on the family.

Population Studied: We included all children (2,689) with complete data on the 49 questions measuring severity, one question measuring the condition’s financial impact on the family, and one question measuring the number of hours caregivers spent arranging for their child’s care.

Principal Findings: SEM demonstrated that a bifactor model with a general factor (on which all items loaded) measuring ASD severity and a specific factor (consisting of a small item subset) measuring social difficulties, best represented the scale’s structure. SEM indicated that increased ASD severity significantly predicted an increased financial impact on the family (b = 0.22, p < 0.01) and that severity’s influence on hours arranging care partially mediated this relationship. Social problem severity did not significantly predict financial impact or hours arranging care.

Conclusions: To best derive severity score for the 46 Pathways items measuring severity, stakeholders should use SEM-based methods to best measure general and social severity. As ASD severity increased, the financial impact on
the family increased. Hours arranging care partially mediated this relationship.

**Implications for Policy, Delivery, or Practice:** Findings indicate that stakeholders can create a general ASD severity score from the 46 Pathways items. However, without SEM, the score will confound general and social severity. Second, results show that efforts to reduce ASD’s financial impact should focus on interventions that reduce the number of hours caregivers spend arranging care, especially for children experiencing the most severe symptomatology.

**The MMR Vaccine Autism Controversy: Did Autism Concerns Affect Vaccine Take-Up?**

Lenisa Chang, University of Cincinnati

**Presenter:** Lenisa Chang, Ph.D., Assistant Professor, Economics, University of Cincinnati, lenisa.chang@uc.edu

**Research Objective:** As a result of In the wake of strong (although later refuted) claims of a link between autism and the measles-mumps-rubella (MMR) vaccine, I examine whether fewer parents immunized their children and if there was a differential response by mother’s education level. This task is complicated because the controversy in the US coincided with expansions in public insurance coverage for children and other programs that affect childhood immunizations, as well as another controversy regarding mercury containing preservatives in childhood vaccines.

**Study Design:** Observational study using the US National Immunization Survey from 1995-2006. Use a time trends analysis and a few differing strategies that compare the take up of MMR to other vaccines.

**Population Studied:** Children between 19 months and 36 months old.

**Principal Findings:** I find that the MMR-autism controversy led to a decline of at least 2 percentage points in the take up of MMR and a negative spillover onto other vaccines. I find some evidence that more educated mothers responded more to the controversy, which is consistent with the hypothesis that more educated individuals absorbing health information more quickly. However, this disparity persisted, albeit to a smaller scale, even after new research and information about the lack of such link became widespread in the media.

**Conclusions:** Media plays an important role in the information of parents about vaccines and parental education has a complicated relationship with children's health outcomes.

**Implications for Policy, Delivery, or Practice:**

**Assessing Teen Health Literacy Using Brief Screening Items**

Deena Chisolm, The Ohio State University; Elizabeth Earley, Nationwide Children’s Hospital; Kelly Kelleher, Nationwide Children's Hospital; Sarah Scholle, National Committee on Quality Assurance

**Presenter:** Deena Chisolm, Ph.D., M.S., Associate Professor, Research Institute at Nationwide Children's Hospital, The Ohio State University, chisolm.1111@osu.edu

**Research Objective:** Youth-reported data are an important but underutilized component of pediatric healthcare quality measurement. To integrate youth-reported measures in quality assessment systems, however, we must consider how health literacy is associated with competence to complete surveys in written, telephone, or computerized format. Administration of a health literacy assessment along with a youth-reported quality of care survey could allow assessment of reliability and validity to be stratified by literacy level but the lack of validated self-report health literacy items for teens has made such an undertaking difficult. This pilot study assesses the relationship between interviewer-assessed and self-reported health literacy in an adolescent population as preliminary research for developing proxy measures that can be included in surveys of youth reported health care quality.

**Study Design:** Respondents completed the REALM-Teen and three health literacy screening items previously tested in adult populations. These items assess confidence in completing health forms, use of help in reading health materials, and difficulty understanding written health information.

**Population Studied:** 205 youths, between the ages of 12 and 18, were recruited from three sources: the adolescent medicine clinic at Nationwide Children's Hospital (n=60), a general email sent to the staff of NCH (n=61), and Medicaid managed care enrollees with chronic health conditions (n=84).
**Principal Findings:** The mean respondent age was 15.9, 59% were female, and 62% were White. Overall, 16% of youths were identified as having inadequate health literacy (REALM-Teen score <=44) and an additional 27% had marginal scores (REALM-Teen 45-60). Inadequate health literacy was most common in the clinic population (25%) compared to the general (15%) and chronic illness (7%) samples. No significant age difference was seen. Over half of the population (55%) reported at least one health-literacy related limitation on the screening items, with 36% always or usually using help to read materials, 23% reporting problems learning about health due to difficulty reading, and 31% feeling only somewhat confident in completing forms. The chronic disease population reported higher limitations in form literacy. Boys had higher rates of accessing help to read materials. The literacy screening items demonstrated moderate significant bivariate correlations with the REALM-teen (range r=0.29-0.36). Summing the three items to create a composite score increased the correlation with the REALM-Teen to 0.43.

**Conclusions:** Limitations in health literacy are evident in a noteworthy proportion of adolescents, particularly minorities and clinic-based teens. Based on our correlational analysis, we believe that a reasonable proxy indicator can be created to identify lower-literacy youths completing health surveys.

**Implications for Policy, Delivery, or Practice:** Including such a proxy will allow development of analytic methods for addressing responses from respondents with lower literacy. It will also allow testing of whether health literacy differentially influences responses to surveys offered through different modes (e.g., telephone, paper, electronic)

**Morning Bell: The Effect of Earlier School Days on Adolescent Health and Academic Outcomes**

Heather Dahlen, State Health Access Data Assistance Center (SHADAC)

**Presenter:** Heather Dahlen, M.A., B.A., B.B.A., Research Assistant, State Health Access Data Assistance Center (SHADAC), heather.mattson@gmail.com

**Research Objective:** To examine how changing school start times affect body mass index (BMI), academic performance, and behavioral outcomes of elementary school-aged children.

**Study Design:** The study utilizes the nationally representative Early Childhood Longitudinal Survey- Kindergarten cohort (ECLS-K) to analyze the impact of moving school starts time on child academic and behavioral outcomes. Students who attended schools where the start of the academic day was moved from late (8:00 a.m. or after) to early (prior to 8:00 a.m.) between two waves of data collection (third and fifth grade) were identified. This “natural experiment” led to models that exploit this variation over time (comparing pre- and post-changing start time periods) and across student population groups (comparing students in schools that did change their starting time to those that did not). The dependent variables are the child outcomes—test scores, behavioral measures, and BMI. The ECLS-K provides information on math, science, and reading scores. The behavioral outcomes include measures of self-control, anxiety, and aggression toward other students. Lastly, BMI is measured using a child’s height, weight, and age in months. All dependent variables are found in the third and fifth grade waves of data. The methodology used is a difference-in-differences model that allows the effects of school start time to be disentangled from other aspects of school policy as well as the underlying trends in child educational production functions. Whereas prior studies have focused on local, district-level data, this is the first to utilize nationally representative panel data.

**Population Studied:** Children between the ages of eight and eleven (third through fifth grade).

**Principal Findings:** Initial descriptive statistics suggest that children whose schools moved the school day to an earlier time between third and fifth grade had lower test scores, poorer behavioral scores, and higher BMIs in fifth grade than children whose schools did not change start times. Preliminary findings suggest the magnitude of these changes increase as the minutes increase; students whose days were pushed up more than 30 minutes during the two time frames had larger declines in test scores, bigger instances of behavioral problems, and larger increases in BMI than those whose days were only moved 15 minutes (all relative to the control group of unchanged start time students).

**Conclusions:** Moving school start times to earlier in the day might have unintended consequences. Recent sleep pattern research
has discovered that adolescents have different circadian rhythms than adults, suggesting that when school days begin earlier children lose sleep and simply cannot make up the loss by going to bed earlier. When students are sleepier their school work, behavior, and weight are all potentially negatively affected.

Implications for Policy, Delivery, or Practice: As academic start times are made earlier, there might be some negative effects on child development. While there are many valid reasons for beginning the school day earlier, such as additional daylight after school for extracurricular activities, more time with family and homework, and cost savings through shared busing services, they are not without potential drawbacks.

Poster Session and Number: A, #156

The Impact of Maternal Depression on Child Academic and Socioemotional Outcomes
Heather Dahlen, State Health Access Data Assistance Center (SHADAC)

Presenter: Heather Dahlen, M.A., B.A., B.B.A., Research Assistant, State Health Access Data Assistance Center (SHADAC), heather.mattson@gmail.com

Research Objective: To test whether maternal depression affects child cognitive and non-cognitive outcomes, including the impacts of severity and duration of maternal depression.

Study Design: This study uses nationally representative data from the Early Childhood Longitudinal Survey--Kindergarten cohort (ECLS-K). Three methodological approaches were used to estimate the effect of maternal depression on child outcomes: 1. Value-added regression models that used the lagged child outcome measure of interest as a control for unmeasured covariates in later years of schooling, 2. Inverse probability weighted models that adjusted for preexisting observed differences between the treatment (those with depressed mothers) and control (those without) groups, and 3. Bounding of the causal effects of maternal depression using a technique established by Altonji, Elder and Taber (2005). A key contribution to the literature on maternal depression and child outcomes results from the inclusion of the bounding methodology, as it uses the difference in observed traits across children associated with mothers that have varying degrees of depression to demonstrate both the size and direction of the role of the unobserved variables affecting the results.

Population Studied: Elementary school-aged children (Kindergarten through eighth grade).

Principal Findings: For Kindergartners, any or moderate depression in their mothers led to reductions in math scores of 0.07 and 0.06 standard deviations. Third graders with moderately depressed mothers had a .1 standard deviation reduction in reading scores. Eighth grade students had rather large reductions in both math and reading scores when their mothers experienced either any or moderate depression levels, with scores ranging from 0.05 to 0.15 standard deviations lower than their counterparts whose mothers were not depressed. While severity did not impact test scores, it did play a role in non-cognitive outcomes. For kindergartners whose mothers were moderately depressed, they scored 0.08 standard deviations lower in interpersonal skills and this nearly doubled to 0.13 standard deviations when their mother was severely depressed. This pattern was similar for externalizing problem behavior and internalizing problem behavior as well, suggesting severity of depression might play a stronger role when children are younger. In terms of chronicity, my results show that if the mother is depressed both when the child is in kindergarten as well as third grade, many of the outcomes are adversely affected (math and reading scores, approaches to learning, self-control, and problem behavior). However, there were no chronicity effects for eighth graders.

Conclusions: Results indicate that maternal depression negatively affects both cognitive and noncognitive child development. Across all years in the panel, the presence of maternal depression adversely impacts at least one child outcome, and the results were often stronger for the socioemotional outcomes than test scores. Additionally, both severity and chronicity of maternal depression matter and dampen child outcomes. Following the bounding correction for endogeneity, my results remain significant, indicating that the effects of maternal depression on child outcomes are not driven by unobservable variables affecting the results.

Implications for Policy, Delivery, or Practice: Prior research has established the positive link between maternal depression and income. My results demonstrate that there are spillover effects of maternal depression on child development. Thus, one policy implication might
be to strengthen the depression screening mechanisms for income-tested government programs and provision of depression treatment. When mothers are mentally unhealthy, I have shown that they spend less time on child development, leading to detrimental effects for the child in school. For the teachers of such children, spending extra time with them either assisting learning or correcting negative socioemotional behaviors reduces the total time he or she has with the rest of the class. By increasing the treatment of depression, it is more than just the mother who is helped.

**Poster Session and Number:** A, #157

**Research Objective:** We sought to implement a process for the timely development and review of measures required under the Children’s Health Insurance Program Reauthorization Act (CHIPRA) in time for posting by January 2013.

**Study Design:** AHRQ and CMS awarded grants to 7 CHIPRA Centers of Excellence (COEs), and assigned the COEs 43 measure topics for development or enhancement; priorities were selected based on CHIPRA requirements and gaps, importance, and the likelihood of an evidence base. A set of critical CHIPRA-specific desirable attributes was identified collaboratively, and codified in a CHIPRA Candidate Measure Nomination Form (CPCF) that was used for public and COE measure nominations. A Subcommittee of the AHRQ National Advisory Council (SNAC) used information provided in the CPCF and a Modified Delphi approach (3 rounds) to assess the measures and make recommendations.

**Population Studied:** Children, adolescents and pregnant women enrolled in Medicaid or CHIP.

**Principal Findings:** 77 measures in total were submitted: the SNAC reviewed the 63 measures with minimally sufficient information. The SNAC recommended 5 measures for potential voluntary use by Medicaid and CHIP and 2 for other uses. Recommended measures addressed key clinical areas of adolescent vaccination, asthma medication management, prenatal care, adolescent tobacco use, and appropriate use of CT scans. CMS, taking into consideration programmatic importance and the capacity of State programs and CMS itself, recommended 3 of the measures as additions to the Medicaid and CHIP core set.

**Conclusions:** The 2012 process implemented to meet CHIPRA requirements for improvements to the core set and to develop measures for other uses was complex but orderly and successful.

**Implications for Policy, Delivery, or Practice:** Several additional measures have been vetted and are available for assessing the quality of health care services for children and pregnant women in Medicaid and CHIP and other public and private programs, and to guide quality improvement efforts.

**Introducing and Scaling Up Integrated Community Case Management of Childhood Illness: Findings from the Child Survival and Health Grants Program**

S. Katherine Farnsworth, U.S. Agency for International Development; Laban Tsuma, ICF; Kirsten Unfried, ICF; Elizabeth Jenkins; David Marsh, Save the Children

**Presenter:** S. Katherine Farnsworth, M.A., Technical Advisor, Health, Infectious Diseases and Nutrition, U.S. Agency for International Development, skfarns@gmail.com

**Research Objective:** Despite recent improvements in some developing countries, morbidity and mortality in children under five remains unacceptably high. A growing body of evidence supports the integrated Community Case Management (CCM) of childhood illness. A critical element in reducing mortality from the primary causes of death in children, CCM targets conditions that account for a large percentage of childhood deaths and for which effective treatments are available, namely: pneumonia, diarrhea, and malaria.

As CCM programs expand, there are areas where the global community is interested to
capture key lessons from implementation experience. In 2012, USAID through its Child Survival and Health Grants Program (CSHGP) conducted a systematic review of its projects and operations research to assess policy and program barriers that limit treatment of childhood illness. The objective was to assess the learning potential of projects, facilitate the scale up of key findings, and ultimately improve the effectiveness, equity, and quality of child health services.

**Study Design:** The study was conducted in four parts: a desk review to “landscape” the portfolio of CCM projects; a review of project monitoring indicators; benchmark maps; and case studies. The availability of information was quantified, and we described the portfolio based on project description; national context; project approaches; implementation; and results by access, quality, demand, environment, coverage and morbidity and mortality.

**Population Studied:** We screened 152 projects, identifying 10 completed and 12 on-going projects fulfilling CCM criteria. Nearly all projects were implemented at meaningful administrative scales (one or more districts) using official cadres to deliver CCM, which further increases the potential for health system learning. Nearly all were in rural sub-Saharan Africa.

**Principal Findings:** The landscape survey yielded modest results, but the benchmark survey and the case studies strongly suggest that CSHGP grantees have positively enabled many national environments for CCM. Benchmark maps, especially when corroborated by third parties, confirm the contributions of grantees in many components across several countries. CSHGP projects have and are measuring performance data for each of the eight CCM benchmark components. In total, the 21 projects tracked 140 indicators to monitor CCM performance, of which 51 closely match recommended indicators, with another 89 measuring similar phenomena by different metrics.

Nine projects are conducting research to inform priority CCM operations research questions. One project in Cameroon reported changes in the morbidity profile of pneumonia concomitant with introducing CCM. Two projects were able to demonstrate large reductions in under-five mortality rates through a marked increase in the coverage of all three treatment interventions.

**Conclusions:** Given the adverse mortality, ecologic profile, and the likely cause-structure of child mortality in project sites, CSHGP project settings are well-suited for CCM. Generalizing results requires caution because these impact areas are generally more challenging than typical rural African settings. Nevertheless, it was found that CSHGP projects build CCM capacity by sharing, championing and supporting the global CCM research agenda.

**Implications for Policy, Delivery, or Practice:** Informed by the review and emerging global experience, several notable “best practices” for CCM were identified. Cost-recovery schemes within CCM could inform the equity vs. efficiency debate surrounding user fees. In addition, alternative financing mechanisms are being explored in different settings, such as insurance and health savings groups. Annual benchmark mapping would allow tracing common paths for countries as they introduce and scale up CCM.

**Funding Source(s):** Other, USAID

**Poster Session and Number:** A, #159

**Socioeconomic Status and Hospitalization Costs for Common Pediatric Conditions**

Evan Fieldston, University of Pennsylvania School of Medicine & CHOP; Isabella Zaniletti and Matthew Hall, Children's Hospital Association; Jeffrey Colvin, University of Missouri-Kansas City School of Medicine; Laura Gottlieb, University of California San Francisco School of Medicine; Michelle Macy, University of Michigan School of Medicine; Elizabeth Alpern, University of Pennsylvania School of Medicine; Rustin Morse and Paul Hain, Children's Medical Center, Dallas; Samir S. Shah, University of Cincinnati School of Medicine

**Presenter:** Evan Fieldston, M.D., M.B.A., M.S., Assistant Professor, Pediatrics, University of Pennsylvania School of Medicine & CHOP, fieldston@email.chop.edu

**Research Objective:** Child health and development are influenced by biomedical and socioeconomic factors. Few studies have explored the relationship between community-level income and inpatient resource utilization for children. To analyze inpatient costs of care for children with common medical conditions at freestanding children’s hospitals in relation to their home ZIP code’s median annual household income (HHI). We hypothesized that hospitalized children from areas with lower median HHI would have higher costs.

**Study Design:** Retrospective cohort study focused on 5 common All Patient Refined
Diagnostic Related Groups (APR-DRG): asthma, diabetes, bronchiolitis & RSV pneumonia, pneumonia, and kidney & urinary tract infections. Main exposure was median annual HHI, divided into 4 groups (based on multiples of federal poverty level). Standardized costs of hospitalization care were modeled using mixed-effects methods for each APR-DRG. Costs were adjusted for severity of illness. Analyses were done at the hospitalization level and patient level. Post-hoc tests compared the adjusted standardized costs of patient in the lowest and highest income groups.

**Population Studied:** 105,619 pediatric patients at 32 freestanding children's hospitals in the Pediatric Health Information System (PHIS) from 2010-2011 with 5 common medical diagnoses. Main exposure of interest was MA-HHI, divided into 4 groups (based on multiples of federal poverty level).

**Principal Findings:** There were 116,631 hospitalizations: 3 of 5 conditions had differences at the hospitalization level and 4 of 5 had differences at the patient level, with the lowest-income groups having higher costs. The hospitalization level cost difference ranges from $205 (asthma, p=0.001) to $539 (diabetes, p<0.001), translating to differences of 5.6% to 8.8%, respectively. At the patient level, the cost difference range was $153 (3.4%) (pneumonia, other p<0.05) to $1401 (22.1%) (diabetes, p<0.001). Higher costs were typically for room costs, not for lab, imaging, or pharmacy costs.

**Conclusions:** Lower community-level household income is associated with higher inpatient costs of care for 4 of 5 common pediatric conditions.

**Implications for Policy, Delivery, or Practice:** These findings highlight the need to consider socioeconomic status in healthcare system design, care delivery, and reimbursement calculations.

**Funding Source(s):** No Funding

**APR-DRG Severity of Illness Scores Correlate Poorly with Clinical Risk Scores in Pediatric Cardiac Surgery**
Lisa Mcleod, University of Pennsylvania School of Medicine; Evan Fieldston, University of Pennsylvania & CHOP; Sara K. Pasquale, University of Michigan School of Medicine; Andrea T. Kennedy, The Children's Hospital of Philadelphia; Janine M. Pappas, The Children's Hospital of Philadelphia; J. William Gaynor, University of Pennsylvania School of Medicine; Evan S. Fieldston, University of Pennsylvania School of Medicine

**Presenter:** Evan Fieldston, M.D., M.B.A., Assistant Professor, University of Pennsylvania & CHOP, fieldston@email.chop.edu

**Research Objective:** All Patient Refined Diagnosis Related Groups (APRDRG) severity of illness (SOI) scores are often used to adjust for patient risk in outcomes and quality analyses using administrative data. It is not known whether SOI scores correlate more with intrinsic patient risk at the time of a hospitalization/procedure, or with complications occurring later in the hospital stay. Our objective was to determine the association between SOI, markers of patient and procedure risk, and peri-operative complications in children undergoing cardiac surgery.

**Study Design:** Clinical data from the Society of Thoracic Surgeons (STS) Congenital Heart Surgery Database were linked to administrative data from the Pediatric Health Information Systems (PHIS) Database for patients 0-18 yrs undergoing cardiac surgery with bypass at our institution (2007-11). Correlation (rho) between SOI score (from PHIS) and a validated metric of cardiac case complexity/ risk (STS STAT score) was determined. Logistic regression was used to assess the impact of peri-operative complications on SOI score stratified by STAT category, and adjusting for patient pre-operative characteristics (age, weight, genetic syndrome, and other STS pre-operative risk factors).

**Population Studied:** Pediatric patients 0-18 yrs old undergoing cardiac surgery with bypass at The Children’s Hospital of Philadelphia between 2007-11.

**Principal Findings:** We evaluated 1,614 operations on 1,404 children (22% neonates, 36% infants, 41% children). Mean SOI and STAT scores were 2.8(SD 0.97) and 2.3(SD 1.3), and 41% of patients had =1 complication. Overall, correlation between STAT and SOI scores was 0.51, and was lower in neonates and infants (rho=0.29, 0.20) than in children (rho=0.41). In analysis stratified by STAT category, and adjusting for patient pre-operative characteristics, those with ICD9 codes indicating peri-operative complications had higher SOI scores across all STAT categories, with the greatest effect in the lower STAT categories.

**Conclusions:** In children undergoing heart surgery, those with similar procedural risk scores and pre-operative characteristics were
more likely to have higher SOI if they had a complication.

Implications for Policy, Delivery, or Practice:
These findings suggest that SOI is not appropriate for severity/acuity adjustment, as it reflects a combination of pre-operative/procedural risk and peri-operative complications. Further research is needed to evaluate whether this holds true for other conditions.

Effect of a School-Based Health Promotion Program on Children in Primary Schools: A Cluster Randomized Controlled Trial
Ludwig Grillich, Danube Univeristy Krems; Christina Kien, Danube Univeristy Krems; Gerald Gartlehner, Danube Univeristy Krems

Research Objective: To assess the effectiveness of a school-based health promotion program to improve motor-skills, physical activity, physical and psychological well-being, and emotional and social experiences in schoolchildren aged 8 to 11 years.

Study Design: The design of our study was a cluster randomized controlled trial (CRCT) with a follow-up of two years (Trial registration DRKS00000622 – German register of clinical studies). The units of randomization were school-classes. After baseline assessment, 53 classes from 45 elementary schools in Austria were randomly assigned to an intervention (n=26) or control arm (n=27). The intervention consisted of 36 hours of teacher education: 20 hours of individual training on how to teach in a way that includes the need of the children for physical activity and 16 hours of group training on theoretical backgrounds and practical didactical technics (e.g., Running Dictation).

The control group received no intervention. The final assessment took place in April 2012. The main outcome measures included Emotional Quality of Life in Classroom, Social Quality of Life in Classroom, Psychological Quality of Life, Physical Quality of Life, Motor Skills, Physical Activity and Ability to Concentrate. All outcomes were measured in children with published valid and reliable instruments. The statistical analysis was done using a Multilevel Analysis (MLA) with nested set. R with the NLME package. We used “Full Information Maximum Likelihood” (FIML) to estimate missing data.

Population Studied: 840 elementary school children aged 8 to 11 years (intervention n = 397; control group n = 443).

Principal Findings: At baseline the parents agreed to their children’s participation in the study. 816 children (mean age of 8.7 years, 50% female) completed the baseline and follow-up assessments.

Children in the intervention arm compared with the control showed significant differences in one of the seven outcomes. In Motor Skills they had more Precise Body Coordination (p < 0.01), faster Ability to respond (p < 0.01) and better Spatial Orientation (p < 0.01). But there were no significant results in Kinesthetic Differentiation Capability (p = 0.47) and Coordination under Time Pressure (p = 0.24). Also the other five outcomes showed no significant results.

Conclusions: The school based health promotion program had a positive effect on the coordinative abilities of children in this program.

Implications for Policy, Delivery, or Practice: The findings of this evaluation showed that the program has a positive effect on Motor Skills of children, so the study delivers some evidence for decision makers to continue with this particular health promotion program in schools. However there is also need for optimizing, five relevant outcomes showed no significant results. Thus, it is recommended that improvements are made to the intervention theory of the program and to reconsider the number of hours of teacher intervention.

Falling Far Short of the Surgeon General’s Recommendation: A National Picture of Human Milk for Infants in Neonatal Intensive Care
Sunny G. Hallowell, University of Pennsylvania; Diane L. Spatz, Ph.D., R.N., FAAN, University of
Pennsylvania School of Nursing; Alexandra L. Hanlon, Ph.D., University of Pennsylvania School of Nursing; Eileen T. Lake, Ph.D., R.N., FAAN, University of Pennsylvania School of Nursing

Presenter: Sunny G. Hallowell, Ph.D., Pediatric Nurse Practitioner, Lactation Consultant, University of Pennsylvania, hallowellnp@gmail.com

Research Objective: In 2011, the U.S. Surgeon General’s Call to Action asked healthcare professionals to support breastfeeding as the standard of care in all settings caring for women and children. An unprecedented declaration by the American Academy of Pediatrics followed, identifying breastfeeding and the receipt of human milk as the normative standards for infant feeding and nutrition. Evidence of the indisputable nutritional, immunological and behavioral benefits of human milk prompted the endorsement by the Joint Commission and the National Quality Forum of the use of “exclusive breast milk feeding” as a perinatal standard for full-term infants in the postpartum setting. Despite evidence that early receipt of human milk reduces the risk of morbidity and mortality, especially among very low birth weight (VLBW) infants, a high-risk pediatric population that comprises half of infant deaths annually, this standard has not been applied to the neonatal intensive care unit (NICU). The purpose of this study was to measure the frequency of breastfeeding support by nurses and receipt of human milk by VLBW infants in the NICU, which is not known. We also determined if the numbers and qualifications of nurses, their professional practice environment and the availability of lactation consultants increased the number of infants who received this care.

Study Design: This cross-sectional, secondary analysis utilized 2008 nurse survey data from the parent study funded by the Robert Wood Johnson Foundation, and infant hospitalization data from 104 NICUs in the Vermont Oxford Network (VON), a NICU quality collaborative. In 2008, the US VON centers comprised 578 hospitals, which included approximately 65% of NICUs and 80% of all VLBW infants born in the United States. These are the only national multihospital data available on the receipt of human milk in any newborns. Study measures were constructed at the NICU-level from 6060 nurse survey respondents, the 15,233 infants nurses cared for on their last shift worked, and 7886 VLBW infants cared for on these units from the VON database.

Population Studied: VLBW infants in NICUs.

Principal Findings: Hardly any infants (6%) were discharged on exclusive human milk. The majority (54%) were discharged on formula only. The remaining infants (42%) received human milk mixed with fortifier or formula. Nurses reported providing breastfeeding support to one in five infants whose parents were present. Sixty percent of infants had parents present for part or the entire shift. Most NICUs (64%) had no lactation consultants. Significantly higher fractions of infants received breastfeeding support and human milk (p < .05) in NICU’s with supportive professional practice environments, baccalaureate-prepared nurses, and nurses with at least five years NICU experience.

Conclusions: The country is falling far short of the Surgeon General’s recommendation for this high-risk pediatric population. The findings suggest that NICU nurses provide breastfeeding support around the clock, typically without a lactation consultant available.

Implications for Policy, Delivery, or Practice: This study provides evidence that nurses are essential to providing lactation care to NICU infants, for whom the receipt of human milk is an issue of patient satisfaction, quality patient care, effectiveness, and survival.

Cost-Sharing, Income, and Financial Barriers to Care among Children with Asthma
Courtnee Hamity, Kaiser Permanente; Vicki Fung, Mid-Atlantic Permanente Medical Group; Ilana Graetz, Kaiser Permanente Division of Research; Alison Galbraith, Center for Child Health Care Studies, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute; Jie Huang, Kaiser Permanente Division of Research; John Hsu, Mongan Institute for Health Policy, Massachusetts General Hospital, Harvard Medical School; Ann C. Wu, Center for Child Health Care Studies, Department of Population Medicine, Harvard Medical School and Harvard Pilgrim Health Care Institute

Presenter: Courtnee Hamity, Ph.D., Senior Research Associate, Division of Research, Kaiser Permanente, courtnee.l.hamity@kp.org
Research Objective: Patients increasingly are paying for larger shares of their health care costs. There is limited information on how the effects of cost-sharing could vary by household income, especially in pediatric populations. We examined the associations between cost-sharing, income, and changes in care-seeking and financial burden among children with asthma.

Study Design: We conducted telephone and mailed surveys of parents of children with asthma. We assessed whether subjects changed their care-seeking for prescription drugs, office visits, or the emergency department (ED) due to costs. Parents also reported whether they experienced financial burden (borrowed money or cut back on necessities) due to the cost of their child's asthma care. We classified patients as having high cost-sharing if their brand drug and office visit copayments were >$25 and ED copayments were >$50. We classified subjects' potential subsidy eligibility based on whether they were enrolled in Medicaid, SCHIP; not currently subsidized with household income <=400% FPL or income>400% FPL. We used logistic regression and adjusted for patient gender, age, race/ethnicity, parent education, prior asthma hospitalizations/ED visits, cost-sharing, and subsidy status/income.

Population Studied: A stratified random sample of children, ages 4 to 11, with an asthma diagnosis and >=1 controller medication dispensed in 2011 in an integrated delivery system (N=769, response rate=59.0%).

Principal Findings: Overall, 26% of the study population was enrolled in Medicaid or SCHIP; among the unsubsidized, 61% had incomes <=400% FPL and 13% had high cost-sharing. Among all subjects, 3% switched to a cheaper asthma drug, 10% used less medication than prescribed, 7% delayed/avoided an office visit, and 6% delayed/avoided an ED visit due to costs. In multivariate analyses, higher vs. lower cost-sharing was associated with patients more frequently switching to a cheaper asthma medication (10.4% vs. 2.1%, p<0.05), delaying/avoiding an office visit (24.2% vs. 5.9%, p<0.05), and delaying/avoiding an ED visit (14.6% vs. 4.8%, p<0.05). Unsubsidized patients with incomes <=400% FPL vs. >400% FPL were also more likely to delay/avoid an ED visit (9.5% vs. 1.8%, p<0.05). Overall, 16% of subjects reported financial burden due to the cost of their child's asthma care; this was more likely among those with higher vs. lower cost-sharing (OR=28.2% vs. 14.2%), and patients with income<=400% FPL (22.7%), SCHIP (17.5%), or Medicaid (15.0%) vs. income>400% FPL (4.2%, p<0.05 for all comparisons).

Conclusions: Higher cost-sharing is associated with delaying or avoiding office and ED visits among children with asthma, which could lead to worse outcomes. Some parents report financial burdens due to the cost of their child's asthma care; this was more likely among those with higher cost-sharing and income<=400% FPL, including those without subsidies and those enrolled in SCHIP and Medicaid.

Implications for Policy, Delivery, or Practice: The Affordable Care Act (ACA) will extend coverage to many children and includes Medicaid expansions and premium subsidies for families with incomes less than 400% of the federal poverty level (FPL). These coverage expansions could be especially important for children with chronic conditions; however, lower-income children with employer-sponsored coverage or incomes >250% FPL are not eligible for cost-sharing subsidies and may continue to be at higher risk for cost-related problems.

Patterns of Behavioral Health Service Utilization and Diagnoses among Medicaid-enrolled White, Black and Latino Children with ADHD

Melanie Hinojosa, University of Florida; Nancy Rudner, University of Florida, Department of Health Outcomes and Policy; Matthew Van Voorhis, University of Florida, Department of Health Outcomes and Policy; Elizabeth Shenkman, University of Florida, Department of Health Outcomes and Policy

Presenter: Melanie Hinojosa, Ph.D., M.S., Assistant Professor, Health Outcomes and Policy and Institute for Child Health Policy, University of Florida, msh@ufl.edu

Research Objective: Attention deficit-hyperactivity disorder (ADHD), among the most common pediatric disorders, affects 4-12% of school-age children. Non-white children are less likely to be diagnosed with ADHD compared to white children, but when diagnosed, they have more severe or complicated forms of ADHD and more comorbid behavioral health (BH) conditions. Our objective is to examine BH patterns and predictors of health care utilization
patterns among low-income non-white children with ADHD and co-occurring BH conditions.

**Study Design:** Children with ADHD were identified in the database and their outpatient BH service use was examined for the year. Logistic regression analyses examined the likelihood of outpatient visits for co-occurring BH diagnoses among children with ADHD and the associated factors including race, ethnicity, sex, and age of the child, severity of physical health conditions present, and county-level poverty rates.

**Population Studied:** This study utilizes health care claims, encounter, and enrollment data for 21,342 children ages 2 to 18, with a BH diagnosis participating in the Texas Medicaid program in 2010.

**Principal Findings:** A substantial proportion of children with ADHD were seen in outpatient settings for other BH conditions including mood disorders (9.8%), anxiety disorders (9.5%), developmental delays (5.6%), conduct disorders (7.0%), and other mental health diagnoses (13.0%). Black children with ADHD were more likely to have a conduct disorder (OR=1.24, p<.01), developmental delay (OR=1.22, p<.01), schizophrenia (OR=1.81, p<.01) and/or substance use disorder (OR=1.59, p<.01) compared to white children. Latino children were more likely to use health care for developmental delays (OR=1.37, p<.01), and substance use disorder (OR=1.73, p<.01) compared to whites. Factors that predict higher BH outpatient utilization were a) being older, b) having more severe physical health conditions, and living in a county with a higher rate of poverty. Girls with ADHD were more likely to utilized care for mood disorders (OR=1.38, p<.01) and anxiety disorders (OR=1.53, p<.01) compared to boys and were less likely to utilize care related to conduct disorders (OR=.81, p<.01), developmental delays (OR=.77, p<.01), and/or substance use disorder (OR=.54, p<.01).

**Conclusions:** Severity of comorbid physical health conditions, complexity of ADHD diagnosis, gender, age and county characteristics each predicted BH utilization among children with ADHD. Rather than explaining the racial and ethnic disparities, however, including these factors in our model highlighted the disparities. For example, unadjusted models of utilization for substance use disorder showed no difference between races, but adjusted models show Black and Latino children with ADHD were more than 1½ times as likely to have outpatient care for substance use.

**Implications for Policy, Delivery, or Practice:** Future work will focus on determining factors related to the causes of different utilization patterns for co-occurring mental illness in this population including family resources and perceptions of health care. This has implications for developing systems of care to adequately address multiple co-occurring BH conditions especially among racial and ethnic minority children.

**Development of a Suite of Antipsychotic Measures for Youth in Medicaid and in Foster Care**

Molly Finnerty, MD, NYS Office of Mental Health; Edith Kealey; Jennifer Klima, Nationwide Childrens; Emily Leckman-Westin, NYS Office of Mental Health; Kelly Kelleher, Nationwide Childrens; Mark Olfsen, Columbia University; Scott Bilder, Stephen Crystal, Sheree Neese-Todd, Rutgers University; Candice Groseclose, Sepheen Byron, NCQA; Sarah Scholle, NCQA

**Presenter:** Edith Kealey, Research Scientist, edith.kealey@omh.ny.gov

**Research Objective:** As part of a national effort to develop new quality measures for children in Medicaid and CHIP, the National Collaborative for Innovation in Quality Measurement in collaboration with the Rutgers-based MEDNET multistate consortium, is developing measures assessing the use of antipsychotics among children in Medicaid and the Foster Care system. Increased use of antipsychotics among youth, especially publically insured youth, with the highest prevalence for youth in Foster Care, has raised national concerns of appropriateness, safety, and efficiency, and has made antipsychotic utilization a high priority target for quality measure development. This presentation will describe the development and testing of a suite of claims based measures of antipsychotic utilization for the Foster Care and the general Medicaid youth population.

**Study Design:** An environmental scan identified candidate measure concepts. Evidence reviews were presented to three advisory panels, which prioritized among measures and proposed additional measure concepts. An expert workgroup developed draft technical specifications, building upon and expanding the
work of the 16-state Medicaid Medical Directors Learning Network/CERTs Antipsychotics in Children Project, NYS PSYCKES measures, and the measures developed by the MEDNET collaborative. Alternative measure specifications were tested, e.g. continuous enrollment. Measure testing included feasibility, reliability, predictive validity, and disparities for foster care and the general Medicaid population. Feasibility and face validity were also assessed by obtaining feedback from stakeholders.

**Population Studied:** The study population included youth enrolled in the Medicaid program, 0-21 years of age, in Foster Care and in the general Medicaid population. Definitions were tested and measures assessed in three databases: 1) New York State Medicaid database, 2) National Medicaid data (2004 – 2008), and 3) MEDNET 5-state Medicaid database.

**Principal Findings:** A total of 8 antipsychotic utilization measure constructs were generated: 1) antipsychotic polypharmacy, 2) antipsychotic use in very young children, 3) high doses of antipsychotics, 4) metabolic screening for youth on antipsychotics, 5) baseline metabolic screening prior to starting an antipsychotic, 6) use of antipsychotics in the absence of a first line indication, 7) absence of a psychosocial intervention prior to starting an antipsychotic medication, 8) medical follow-up after starting an antipsychotic medication. Input from the advisory panels generally indicated high importance of antipsychotic measures. It was feasible to assess most measures using claims data. However, the validity of some measures would be improved through EMR assessment. In addition, measures that required assessment of mental health services may not be able to be assessed in all states using Medicaid data. Measures needed to be adapted for Foster care due to shorter duration of continuous enrollment in Foster Care, which varied by age.

**Conclusions:** Overall, antipsychotic measures are a high priority for states, and are feasible for states to assess using Medicaid data. Results suggest that most of these measures can be reliably used for Foster Care populations using shorter continuous eligibility criteria.

**Implications for Policy, Delivery, or Practice:** This suite of measures may be useful for states in monitoring antipsychotic utilization among vulnerable populations of youth in Medicaid and their Foster Care programs.

**Utilization Patterns among Adolescents in New Mexico School-Based Health Centers: A Profile of Frequent Users**

Kevin Koenig, AcademyHealth; Tara Trudnak, PhD, AcademyHealth; Gerry Fairbrother, PhD, AcademyHealth; Paula LeSueur, MSN CFNP, Envision New Mexico; Mary Ramos, MD, MPH, FAAP, Envision New Mexico; Jane McGrath, MD, Envision New Mexico; Yolanda Cordova, MSW, New Mexico Office of School and Adolescent Health

**Presenter:** Kevin Koenig, MPP, Research Associate, AcademyHealth, kevin.koenig@academyhealth.org

**Research Objective:** The objectives are to describe the services that are delivered to students in New Mexico’s (NM) SBHCs and to examine differences in diagnoses and services between frequent users and infrequent users of SBHC services.

**Study Design:** An analysis was conducted on medical claims from 61 SBHCs in New Mexico during the 2010-2011 school year. The analysis also included an examination of the most common types of diagnoses or services for “frequent users” (defined as 5 or more visits) and “infrequent users” (1 or 2 visits). A logistic regression was conducted to examine whether behavioral, reproductive, asthma or acute care diagnoses predict frequent use of the SBHC. Odds ratios were adjusted for age, gender and race.

**Population Studied:** Adolescents 14-19 years of age who visited a SBHC during the 2010-2011 school year.

**Principal Findings:** During the 2010-2011 SY, 10,017 students aged 14-19 years made 33,434 visits to SBHCs. Most of the visits were for behavioral health (37%) or reproductive health (28%) services, but 11% of visits were for checkups, with the remaining for “other” conditions, usually acute. Most students (63%) had only one or two visits, but approximately 20% of students were frequent users, with 5 or more visits. These frequent users accounted for 59% of all visits. Frequent users also had different types of diagnoses and services than infrequent users. Frequent users were more likely to have a visit for behavioral (69%) or reproductive health (56%) services, whereas the users with one or two visits were more likely to have a checkup (36%). About one-fifth of student (21%) had at least one psychotherapy

Identifying Children with Complex Chronic Conditions

Elizabeth La, University of North Carolina at Chapel Hill; Tim O’Brien, AccessCare; Lynn Guerrant, AccessCare; Marisa Domino, University of North Carolina at Chapel Hill; Charles Humble, AccessCare; Steve Wegner, Community Care of North Carolina

Funding Source(s): CMS
Poster Session and Number: A, #167

Implications for Policy, Delivery, or Practice: SBHCs appear to fill an important niche in the health care delivery system: providing behavioral and reproductive health services to a high need population. The ability of adolescents to access services where they attend school is an important aspect of the SBHC model of care.

Research Objective: In North Carolina, 53 percent of Medicaid’s child health expenditures are attributed to the 5 percent of children with special health care needs. Medical home and accountable care models, such as Community Care of North Carolina (CCNC) and the Child Health Accountable Care Collaborative (CHACC), have the potential to improve health outcomes and lower health expenditures for children with special needs through better coordination of services and shared responsibility between providers. In order to be successful, these programs must be able to identify the subpopulation of children with special needs who would benefit most from these models of care. The objective of this study was to use administrative data to identify and describe the characteristics of children with complex chronic conditions.

Study Design: We used an iterative approach, incorporating informal feedback from CHACC providers, to select a method for identifying children with special needs in Medicaid data. The initial method relied on hospital admission frequency, costs, and diagnoses between January 1, 2009 and December 31, 2011 (at least 3 admissions in any 365-day period, costs greater than $100,000, and the presence of a chronic diagnosis). Feedback from CHACC providers indicated that information on patients was too outdated. We are currently updating the method for identifying children to rely on hospital admission frequency, duration, and diagnoses between January 1, 2011 and June 30, 2012 (at least 2 admissions or 1 admission with length of stay greater than 30 days and the presence of a complex chronic diagnosis). We used descriptive statistics to summarize demographic characteristics, as well as inpatient and emergency department utilization of the target population.

Population Studied: The initial and modified samples include all children under the age of 17 enrolled in North Carolina Medicaid who met the selection criteria already described. We excluded children with diagnoses related to cancer, infection, mental illness, asthma, or who were pregnant.

Principal Findings: A total of 3,333 children had at least 3 hospital admissions during any 365-day period between 2009 and 2011. These patients had a total of 17,609 hospital admissions (cost=$211.0 million) and 18,562 emergency department visits (cost=$14.6 million). Of these children, 21% (n=699) had costs exceeding $100,000 during the 3-year period. This subgroup had a total of 4,532 hospital admissions (cost=$133.9 million) and 3,953 emergency department visits (cost=$3.3 million). Final results from the updated method of identifying children with complex chronic conditions will be presented in June.

Conclusions: Administrative data can be used to identify children with complex chronic conditions in a timely manner. Using Medicaid data from North Carolina, we identified a small subgroup of children who account for a large amount of hospital utilization and costs.

Implications for Policy, Delivery, or Practice: These methods can be used to help providers...
identify children with complex chronic conditions who are high cost, frequent users of hospital services, and might benefit from medical home or accountable care initiatives.

**Tobacco Use and Smoking Intentions among Fifth-Grade Students**

Joseph Ladapo, Department of Population Health, New York University School of Medicine; Marc N. Elliott, PhD, RAND, Santa Monica, CA; David E. Kanouse, PhD, RAND, Santa Monica, CA; Susan R. Tortolero, PhD, University of Texas Health Science Center, Houston, TX; Michael Windle, PhD, Department of Behavioral Sciences and Health Education, Emory University Rollins School of Public Health, Atlanta, GA; Paula M. Cuccaro, PhD, University of Texas Health Science Center, Houston, TX; William G. Shadel, PhD, RAND, Pittsburgh, PA; Mark A. Schuster, MD, PhD, RAND, Santa Monica, CA; Department of Medicine, Children's Hospital Boston, Boston, MA; Department of Pediatrics, Harvard Medical School, Boston, MA

**Presenter:** Joseph Ladapo, M.D., Ph.D., Assistant Professor, Population Health, Department of Population Health, New York University School of Medicine, jladapo@post.harvard.edu

**Research Objective:** To evaluate the association of sociodemographic characteristics and contextual factors with cigarette smoking and future smoking intentions among fifth-graders living in three US metropolitan areas.

**Study Design:** We used multivariate logistic regression models to examine how cigarette smoking and intentions to smoke within one year are associated with individual and contextual factors previously identified in studies of older adolescents. Guided by social theories of behavior, these include (1) number of friends who smoke, (2) parental disapproval of smoking, (3) parental communication about not smoking, (4) performance in school, and (5) educational aspirations. Communication, which was assessed by asking children how often parents spoke to them about not smoking and about how to say no when asked to smoke, was considered present if students reported frequent conversations. We adjusted for common socioeconomic measures, including gender, race/ethnicity, highest household education, and household income, along with year-assessed to capture smoking trends. Analyses also accounted for the effects of design and nonresponse weights, clustering of children within schools, and stratification by site.

**Population Studied:** 5,119 fifth-grade children and their parents were enrolled in the Healthy Passages study and interviewed between August 2004 and September 2006. Participants were recruited from public schools in Birmingham, Alabama; Houston, Texas; and Los Angeles County, California. We randomly sampled schools with probabilities designed to yield a balanced sample of non-Hispanic black, non-Hispanic white, and Hispanic children.

**Principal Findings:** Twenty-nine percent of the children were black, 22 percent were white, 44 percent were Hispanic, and 5 percent were another race/ethnicity. Mean age was 11 years, median family income was 25,000 to 50,000 dollars, and nearly one-quarter of parents had less than a high school education. The prevalence of ever smoking a cigarette among black, white, and Hispanic children was 9.6, 4.9, and 5.6 percent, respectively. The prevalence of smoking within the past 30 days was 1 percent in each racial/ethnic group. In adjusted analyses, children were more likely to have smoked a cigarette if any of their friends smoked (adjusted odds ratio, aOR 5.1, 95 percent CI 3.8-6.9) or they had trouble with schoolwork (aOR 2.2, CI 1.5-3.3). They were less likely to have ever smoked cigarettes if their parents were college-educated versus not (aOR 0.5, CI 0.3-0.9) or disapproved of smoking (aOR 0.3, CI 0.1-0.6). Similarly, children were more likely to state that they intended to smoke or felt they might smoke in the future if any friends smoked (aOR 4.1, CI 2.7-6.1) or they had trouble with schoolwork (aOR 2.1, CI 1.0-4.4). However, only parental disapproval (aOR 0.2, CI 0.1-0.6) and communication about not smoking (aOR 0.5, CI 0.3-0.8) had protective associations.

**Conclusions:** Preadolescent fifth-graders share some of the same risk factors for smoking that have been found in prior studies of older adolescents, and parental disapproval and communication about not smoking may dampen future intentions to smoke.

**Implications for Policy, Delivery, or Practice:** Preventive school-based anti-smoking programs and mass media campaigns, which have largely emphasized peer influences and health harms, may benefit from greater emphasis on parental
influence related to communication and expressed disapproval of smoking.

**Nursing Care Rationing Linked to Practice Environments in Pediatric Settings**  
Eileen Lake, University of Pennsylvania; Pamela De Cordova, University of Pennsylvania; Sharon Barton, Children's Hospital of Philadelphia; Shweta Singh, University of Pennsylvania; Linda Aiken, University of Pennsylvania

**Presenter:** Eileen Lake, Ph.D.,R.N., Associate Professor, School of Nursing, University of Pennsylvania, elake@nursing.upenn.edu

**Research Objective:** Better nursing practice environments are known to be associated with better nurse and patient outcomes. Researchers have examined the practice environments of critical care, psychiatric, and adult medical-surgical nurses. However, there is a paucity of evidence about pediatric nursing practice environments. Our objective was to examine nurse rationing as measured by nursing tasks left undone and link it to the practice environment in pediatrics.

**Study Design:** A secondary analysis of cross-sectional nurse survey data from 2006 was conducted. Pediatric nurses were asked on the most recent shift of work, what specific tasks were required but left undone because of limited time to complete them. These included: adequate patient surveillance, skin care, teaching patients, administering medications, documentation, coordinating patient care, pain management, oral hygiene, treatments, preparing for discharge, develop or update care plans, and comforting patients. Nurses were also surveyed about the practice environment using the NQF-endorsed Practice Environment Scale of the Nursing Work Index (PES-NWI) which includes five subscales of the following domains: Collegial Nurse-Physician Relations, Staffing and Resource Adequacy, Manager Leadership and Support, Nursing Foundations for Quality, and Nurse Participation in Hospital Affairs. Nurse-level data were aggregated to the hospital-level after establishing reliability of the subscales. A composite of the five sub-scales was computed and quartiles were created (i.e., bottom 25%, middle 50%, top 25%). One-way ANOVAs and multivariate regression models were used to test for associations between the PES-NWI composite and the fraction of nurses in each hospital who reported each task left undone.

**Population Studied:** There were 335 hospitals included from California, Florida, New Jersey, and Pennsylvania representing hospitals with substantial pediatric patient populations and pediatric nurses.

**Principal Findings:** Of 12 tasks that nurses could identify as being left undone, most were left undone by 13% of the nurses, but this varied from 2% to 28%. Develop or update care plans was left undone most frequently (28%) and pain management was rarely not done (2%). Nurse practice environments were rated as favorable (composite exceeding 3.0) for 25% of hospitals. The subscales with the most and least favorable ratings were Nursing Foundations for Quality (mean = 3.08) and Manager Leadership and Support (mean = 2.65). For 10 of the 12 tasks analyzed, there was a statistically significant relationship between the practice environment and tasks left undone (p <0.01). Overall, hospitals in the top quartile of the practice environment had the fewest tasks left undone. Likewise, hospitals in the bottom quartile had the highest percentage of tasks left undone.

**Conclusions:** One in ten pediatric nurses cannot complete required care. Nurses in pediatric care settings that have better practice environments may have to ration care less often which should have benefits for patients.

**Implications for Policy, Delivery, or Practice:** To decrease nurse rationing of care in pediatrics, hospitals should place emphasis and efforts on improving practice environments. Further research should examine how tasks left undone in less professional practice environments may impact pediatric patient safety.

**An Evidence-Based Care Pathway with Quality Indicators for the Management of Adolescent Depression**  
Eric Lewandowski, NYU Child Study Center; Mary C. Acri, NYU Child Study Center; Kimberly E. Hoagwood, NYU Child Study Center; Sarah H. Scholle, National Committee for Quality Assurance; Sepheen Byron, National Committee for Quality Assurance; Andrea Ireland, National Committee for Quality Assurance; Samantha Frank, NYU Child Study Center; Sarah M. Horwitz, NYU Child Study Center
Presenter: Eric Lewandowski, Ph.D., Research Scientist, Child and Adolescent Psychiatry, NYU Child Study Center, eric.lewandowski@nyumc.org

Research Objective: Care for adolescent depression is suboptimal and could be improved through the development and use of quality indicators. The goal of this work was to develop quality indicators for adolescent depression to be used for quality monitoring and improvement, and for reporting by clinics, health plans and states for meaningful use incentives.

Study Design: Quality indicators for the identification and management of adolescent depression were developed based on clinical practice guidelines and empirical research. Candidate indicators were refined based on panel reviews by consumers, clinicians, state officials, and experts in child psychiatry, pediatrics, and quality measurement.

Population Studied: This work focused on adolescent depression, a prevalent and disabling condition resulting in emotional suffering as well as social and educational dysfunction.

Principal Findings: Based on guidelines, empirical literature, panel review, and expert consultation, an 11-step care pathway was developed for the management of adolescent depression in primary care and specialty mental health settings from case identification through symptom remission, including: screening; diagnostic assessment; suicide assessment; brief supportive counseling; treatment initiation; chart documentation and communication between providers; treatment adherence for medication and psychotherapy; symptom monitoring and reassessment; remission; treatment adjustment. For several steps in this pathway, there was insufficient evidence on which to base quality indicators; for others, empirical studies and guideline recommendations were not precise enough to guide the specification of quality indicators, despite acknowledgement these steps were important for quality care.

Conclusions: Limitations of the current evidence base and indicator review process will hinder the development and widespread endorsement of quality indicators that would improve depression care for adolescents.

Implications for Policy, Delivery, or Practice: Efforts to address these limitations may take two directions. First, researchers may design studies to provide evidence supporting the development of quality indicators for the management of adolescent depression. Priority areas for research include: developing standardized clinical and suicide assessments that are feasible in primary care, including adaptive computer-based assessment approaches; developing triage algorithms linked to symptom severity to complement diagnostic and suicide assessments carried out by non-specialist providers; establishing the appropriate tools, interval, and feedback systems for symptom tracking during treatment; standardized brief counseling interventions that are feasible in primary care; depression medication adjustment algorithms for adolescents. Second, indicator developers and review bodies may consider adjusting the indicator review and approval process, as well as accepted evidence standards to incorporate research findings from relevant non-adolescent and non-mental health populations, as well as quasi-experimental and indirect or implicit evidence.

Ameliorating Family Impacts among Children with Autism Spectrum Disorder: The Role of Health Care Quality
Katharine Zuckerman, MD, MPH, Oregon Health & Science University; Olivia Lindly, Oregon Health & Science University; Olivia Lindly, MPH, Oregon Health & Science University; Karen Kuhlthau, MA, PhD, Massachusetts General Hospital; Christina Bethell, PhD, MBA, MPH, Oregon Health & Science University

Presenter: Olivia Lindly, M.P.H., Research Associate, Pediatrics, Oregon Health & Science University, lindly@ohsu.edu

Research Objective: This study examined which system of care performance domains are most strongly associated with reduced family financial and employment impacts among children with special health care needs (CSHCN) with current autism spectrum disorder (CSHCN+ASD) relative to either CSHCN with functional limitations or CSHCN who have neither ASD nor functional limitations (CSHCN-ASD).

Study Design: Cross-sectional, parent-reported data from the 2009/10 National Survey of Children with Special Health Care Needs were used to conduct weighted bivariate and logistic regression analyses. Family financial and employment impact dependent variables
included (1) families experienced financial problems due to the child’s health condition(s); (2) families paid >$1000 in annual out-of-pocket medical expenses; (3) family members did not change jobs due to concerns about maintaining the child’s insurance; (4) family members cut-back and/or stopped working due to the child’s health condition(s); (5) families spent $11 hours weekly providing/coordinating care for the child; and (6) families experienced =2 of these five employment or financial impacts. The following Maternal and Child Health Bureau (MCHB) core outcomes were used as key indicators of health care system performance: (1) families were partners in shared decision-making; (2) medical home care receipt; (3) consistent, adequate health insurance; (4) preventive care receipt for early, continuous special health care needs screening; (5) ease of access to community health services; and (6) receipt of transition to adult health care services. A composite measure of whether or not CSHCN met all age-relevant MCHB core outcomes was also used as an independent variable. All analyses were adjusted for race/ethnicity, primary household language, household income, sex, age, geographic region, and insurance type.

Population Studied: A nationally-representative sample of non-institutionalized CSHCN age 3 to 17 years including 28,296 CSHCN-ASD without functional limitations, 6,505 CSHCN with functional limitations and 30,25 CSHCN+ASD.

Principal Findings: Across all health care system performance domains, CSHCN+ASD fared worse than CSHCN-ASD regardless of functional status. CSHCN+ASD were also significantly more likely to experience all financial and employment family impacts than CSHCN-ASD regardless of functional status. Meeting all age-relevant system of care core outcomes significantly reduced the likelihood of experiencing family financial and employment impacts across the three CSHCN subgroups. Among CSHCN+ASD, shared decision-making, medical home care receipt, and ease of access to community health services reduced the adjusted odds of experiencing family financial or employment impacts.

Conclusions: CSHCN+ASD are more prone to experience poor health care quality and family financial and employment impacts relative to other CSHCN, regardless of functional status. Receiving high quality health care may lessen the likelihood of family impacts among CSHCN. CSHCN+ASD and their families may benefit from the system of care domains most closely aligned with medical home care.

Implications for Policy, Delivery, or Practice: Targeted policies and programs advancing improved system of care performance are imperative to reduce family impacts among CSHCN+ASD. Health care delivery models fostering effective care coordination, family-centered care, involvement of families in decision-making, and ease of access to community health services may be especially paramount for organizations and practitioners seeking to promote wellness and ultimately health equity among CSHCN+ASD and their families.

The Effect of the Infant Health and Development Program on Special Education and Therapeutic Service Use at Age 6.5 Years

Jonathan Litt, Beth Israel Deaconess Medical Center; Marie McCormick, M.D., Sc.D., Harvard School of Public Health

Presenter: Jonathan Litt, M.D., M.P.H., Neonatologist, Neonatology, Beth Israel Deaconess Medical Center, jlitt@bidmc.harvard.edu

Research Objective: The aim of this study is to evaluate the effect of participation in an intensive early intervention program for infants with low birth weight (LBW) on receipt of special education and physical and occupational therapy services at early school-age.

Study Design: The Infant Health and Development Program included home visits, child development center attendance, and parent support groups for infants <2500 gram birth weight. A multi-site, randomized trial compared this intensive program to usual pediatric care. We fit logistic regression models to assess program impact on the receipt of special education, remedial math, remedial, physical therapy (PT), and occupational therapy (OT) at age 6.5 years. We also tested for effect modification by key covariates.

Population Studied: The population studied is infants with low birth weight. There were two pre-specified birth weight groups: low birth weight (2001 - 2500 grams) and VLBW (= 2000 grams). There were recruited from 8 geographically distinct academic medical centers in the United States.
Principal Findings: Of the 985 infants in the original sample, 853 participated in 6.5 year follow-up. Fifteen percent (132) received special education, 7% (63) remedial math, and 11% (98) remedial reading, while 4% (38) needed PT and 5% (41) OT. Compared to controls, the intervention group was half as likely to receive remedial reading (OR 0.62, 95% CI 0.39, 0.99), while twice as likely to receive PT (Or 2.11, 95% CI 1.08, 4.12) or OT (Or 1.91, 95% CI 0.99, 3.68). There was no evidence for effect modification by birth or demographic variables. Conclusions: Our finding of decreased odds of receiving remedial reading assistance is consistent with improved cognitive scores at 3 and 5 years in the intervention group. The increased use of therapeutic services at age 6.5 is surprising. This finding likely reflects the effects of the intervention on raising parental awareness of their child’s risk for developmental delays and enhancing parental advocacy skills.

Implications for Policy, Delivery, or Practice: The results of this study highlight limitations in our current assessments of the benefits of interventions for children at risk for developmental problems. It is unclear whether decreased service use stems from lack of availability or increased utilization results from social and cultural differences in the acceptability of intervention services. From a program planning and evaluation perspective, measures of functional status would provide a more refined and meaningful view of children's outcomes beyond service use.

Patient-Centered Medical Home Reduces Odds of High Emergency Department Usage among Children with ADHD

Benyamin Margolis, Health Resources and Services Administration; Sue C. Lin, MS, Health Resources and Services Administration

Presenter: Benyamin Margolis, Ph.D.,M.P.H., Health Scientist, Maternal and Child Health Bureau, Health Resources and Services Administration, bmargolis@hrsa.gov

Research Objective: To determine whether coordinated, ongoing, comprehensive care within a medical home reduced the odds of high emergency department usage (EDU) among children reported to have attention-deficit hyperactivity disorder (ADHD) by a parent/caregiver.

Study Design: We used the 2009/2010 National Survey of Children with Special Health Care Needs (NS-CSHCN). The NS-CSHCN is a national, randomized telephone survey sponsored by the Maternal and Child Health Bureau, Health Resources and Services Administration and administered by the National Center for Health Statistics, Centers for Disease Control and Prevention.

Population Studied: The NS-CSHCN sample consisted of 40,242 children. The survey was administered in English, Spanish, Mandarin, Cantonese, Vietnamese, and Korean. Based on an affirmative response by a parent/caregiver to “Does subject child currently have ADD or ADHD?”, 11,412 children ages 0-17 were classified as having ADHD. Emergency Department Use (EDU) was dichotomized into 0-2 EDU (low) and 3 or more EDU (high) categories. We examined receipt of coordinated, ongoing, comprehensive care within a medical home through bivariate analysis of each Medical Home Quality Indicator component. We included those components with significant chi-squared p-values of <0.05 in the multivariate analysis and controlled for family structure, child’s age, and type of insurance.

Principal Findings: Over 91% (n=10,428) of our sample reported low (0-2) EDU, with the remaining 984 children reported to have made 3 or more visits to the ED in the past 12 months. Although almost 97% of our sample had insurance, the proportion of high EDU children on public insurance was significantly higher than the low EDU group (62.6% vs. 37.6). Relative to the high EDU group, families of children with 0-2 EDU were significantly more likely to report receipt of effective care coordination (Adjusted OR=1.35; 95% CI= 1.06, 1.72), more than twice as likely to report their children had “no problems obtaining referrals when needed” (AOR =2.19; 95% CI= 1.73, 2.77), and almost three times more likely to get help coordinating care (AOR=2.73; 95% CI=1.70, 2.73). Providers were also more likely to listen carefully (AOR=2.06, 95% CI=1.52, 2.78), be sensitive to values and customs (AOR=1.91; 95% CI=1.41, 2.59), provide needed information (AOR=1.77; 95% CI=1.34, 2.35), and make families feel like a partner (AOR=1.71; 95% CI=1.26, 2.31).

Conclusions: Receiving well-coordinated care within a medical home was more likely to reflect the experiences of families of children with low EDU. Our findings identified associations between effective referral, receiving help coordinating care, family-centeredness of care,
and EDU, suggesting high EDU families experience a substantially different primary care experience from those families who report low EDU.

Implications for Policy, Delivery, or Practice: The implementation of family centered elements of medical home relies heavily on clinical provider skills and effective referral protocols. Our study suggests that coordinated care to manage ADHD is associated with fewer ED visits for children with ADHD, possibly due to controlling impulsivity characteristic of ADHD. As a complement to implementing referral guidelines, improving providers’ training and preparedness to enhance listening and sharing skills will help families become better included in assuring their children’s ADHD is well-controlled and thus less likely to engage in behaviors leading to ED utilization.

Poster Session and Number: A, #175

Pediatric Medical Necessity Criteria as a Coverage Coordination Mechanism Between Medicaid and the Health Insurance Exchanges
Anne Markus, George Washington University; Kristina West, George Washington University

Presenter: Anne Markus, J.D., Ph.D., Associate Professor, Health Policy, George Washington University, armarkus@gwu.edu

Research Objective: The study examines the significance of medical necessity (MN) criteria for coordinating seamless coverage for children transitioning between Medicaid and the health insurance exchanges. Our first aim is to investigate how pediatric MN is defined in state Medicaid programs which purchase services from Managed Care Organizations (MCOs) for their enrollees, and whether the same definition is used by contracting MCOs. Our second aim is to identify best practices in pediatric MN definitions that could be used to bridge child health coverage between Medicaid and the exchanges’ Qualified Health Plans (QHPs) in states that will be active purchasers of QHPs, especially for children with multiple conditions.

Study Design: The study method consisted of a desk review of state codes of regulations and administrative codes to extract pediatric medical necessity definitions. The legal language was then compared to the MN criteria in model MCO contracts and two provider manuals per state to examine how the state pediatric MN definition has been replicated in these implementing documents. We reviewed states with a full risk Medicaid managed care (MMC) model as the closest example to states which will act as active purchasers of QHPs.

Population Studied: Over 110 statutes, regulations, contracts and provider manuals in 33 states with a full-risk MMC model in order to determine the applicable pediatric medical necessity criteria.

Principal Findings: All of the states we reviewed have a reference to the EPSDT program and the federally-mandated pediatric MN standard “to correct or ameliorate” in their regulations, meaning that all states cover both rehabilitative and habilitative care. However, this is not consistently reflected in the published MCO contracts and provider manuals, half of which do not have a reference to the standard. In addition, only 9 states have in their regulations a MN criterion that can be interpreted as a preventative standard of care for child health.

Conclusions: Not including pediatric MN standards in MCO contracts can have the effect of delegating to the MCOs the ability to define their own MN standard, which could result in inconsistencies in coverage. This practice could transfer to the coverage decisions within the QHPs in the exchanges. Having a single, statutory defined, pediatric MN definition in compliance with the federal standard will ensure continuous coverage options for children regardless of which health plan they are using. We propose best examples of pediatric MN definitions from states.

Implications for Policy, Delivery, or Practice: Considering the recently proposed Essential Health Benefits regulations, the most notable differences in child health coverage between exchanges and Medicaid would likely be in hearing care and habilitative care in QHPs. Further, exchanges cover pediatric care (including dental and vision) for children up to 19, while EPSDT covers children up to 21 years of age. A comprehensive state pediatric medical necessity definition for all state-contracted or state-regulated plans for children up to 21 years of age will allow children with multiple conditions to receive needed health care. The examples of definitions in this paper can be used by state administrators when developing and implementing exchange regulations on coverage transitions for children.

The Effects of Direct to Consumer Advertising on Medication Use among Medicaid Children with Asthma

Luceta McRoy, Health Administration; Meredith Kilgore, Ph.D., University of Alabama at Birmingham; Robert Weech-Maldonado, Ph.D, University of Alabama at Birmingham; David Bradford, Ph.D., University of Georgia; Nir Menachemi, Ph.D., University of Alabama at Birmingham; Michael Morrisey, Ph.D., University of Alabama at Birmingham

**Research Objective:** National guidelines recommend treatment of asthma with preventive long-term medication, but adherence remains low, resulting in high healthcare utilization among those affected by the chronic disease. Although there are conflicting studies views on the effects of direct to consumer advertising (DTCA) since the easing of restrictions by the Food and Drug Administration (FDA) in 1997, studies have shown some benefits of DTCA including increased medication adherence. However, there are no studies that link DTCA to asthma medication use. The purpose of this study is to examine the effects of DTCA on asthma medication use among children.

**Study Design:** This longitudinal study combined Medicaid administrative data and a national advertising data set on asthma medication from 1999 to 2002. Dependent variable is asthma medication use which includes use of long term and short-term asthma medication drugs. Independent variable is DTCA measured as advertising expenditure by county over the study period. A squared term for DTCA was also used to examine the nonlinear effects of DTCA. Covariates include race measured as whites and blacks; age measured as year at baseline; and gender measured as male and female. As series of logistic regression with population fixed effects were used in the analysis.

**Population Studied:** The sample studied consisted of Medicaid children between the ages of 5 and 18 who had an asthma diagnosis at any time during the study period 1999 to 2002.

**Principal Findings:** The principal findings of the study showed that DTCA significantly increased the likelihood of asthma medication use among all Medicaid children (p < .01) in the study. There were no differences between the effects of DTCA on white and black children’s asthma medication use. DTCA was significantly associated with asthma medication use (p<0.01). At higher levels of DTCA expenditure, the asthma medication use was more likely to decrease (p<.01).

**Conclusions:** The results of this study link DTCA with asthma medication use. However, the effects of DTCA decrease at higher levels of spending. Among Medicaid children, the effects of DTCA on asthma medication use are similar.

**Implications for Policy, Delivery, or Practice:** DTCA provides a gateway to disseminate information that could assist in improved health outcome and should be carefully considered in health policy issues. The findings from this study may also be important for allocation of Medicaid funds for asthma treatment, guidance of organizations and other agencies to reduce the burden of asthma.

Developing and Testing a New Trauma Team Activation Protocol for Use at a Level I Pediatric Trauma Center

Rosemary Nabaweesi, Johns Hopkins Hospital; Paul M. Colombani, Johns Hopkins Medical Institutions; Laura Morlock, Johns Hopkins Bloomberg School of Public Health; Stephen Bowman, National University; Charles Lule, Johns Hopkins Medical Institutions

**Presenter:** Rosemary Nabaweesi, DrPH, MBChB, MPH, Senior Project Analyst, General Pediatric Surgery, Johns Hopkins Hospital, rnbawe1@jhmi.edu

**Research Objective:** To assess the association between Trauma Team Activation criteria and Intensity of Resource Use at an academic pediatric Trauma Center with an urban/suburban catchment area

**Study Design:** We analyzed the performance of the current TTA protocol, developed and tested the sensitivity and specificity of a new TTA protocol as it relates to intensity of resource utilization. Logistic regression and Receiver Operating Characteristic curves were the analytic methods used.

**Population Studied:** Children younger than 15 years of age who sustained a traumatic event and were transported to the Institution's Level I Pediatric Trauma Center by Emergency Medical Services from 2008 through 2011

**Principal Findings:** 1,991 children met the inclusion criteria, 80% of the sample was used in
developing the new TTA and 20% was used for testing the new TTA. The medians for age, length of stay and Injury Severity Score (ISS) were 8 years, 1 day and 4 respectively. The odds of using resources intensely among children with a Glasgow Coma Scale less than 9 (GCSLT9), abnormal pulse, abdominal injury and chest injury were 6, 3, 18 and 9 times those of children who did not meet these criteria. The C-statistic for the Receiver Operating Characteristic (ROC) curve of the logistic regression for Intensity of Resource Use (IRU) was 0.7928 and 0.7964 for the logistic regression on level of TTA assignment.

Conclusions: The newly developed Trauma Team Activation protocol identified criteria of Glasgow Coma Scale less than 9, abnormal pulse, abdominal and chest injuries. When any of these criteria are present will initiate a full Trauma Team Activation.

Implications for Policy, Delivery, or Practice: This research work developed a TTA protocol that has the potential to assign patients to the most appropriate TTA level, thus improving effectiveness and efficiency.

The Number of Smokers at Home Affects Child Asthma Prevalence, Health Care Utilization and Costs

Kevin Nelson, M.D., Ph.D., Fellow, Pediatrics, University of Utah

Research Objective: Smoking and tobacco smoke exposure (TSE) are the largest preventable causes of U.S. medical illness and costs. TSE occurs mostly at home, affecting 32 million U.S. children. TSE is associated with development of asthma and poor asthma control. Decreasing TSE has been the subject of policy and medical interventions. However, little data exist about the effect of the number of smokers in the home on child asthma. We investigated the association between the number of smokers in the home and child asthma prevalence, exacerbation frequency, HCU, and total costs.

Study Design: We used cross-sectional data from the Medical Expenditure Panel Survey (MEPS) from 2001-2009. MEPS is a national survey of HCU and costs. We determined national estimates for asthma prevalence, exacerbations, HCU (ED/hospital admissions, outpatient visits, prescription medications), and total costs in 2009 dollars based upon the number of smokers (0, 1, 2 or 3 smokers) in the child’s residence. We determined the number of adults, including parents, who smoke and live in the child’s residence using datafields for “smoking status” and “number of adults” living in the child’s residence. Asthma exacerbations were captured by the datafields “exacerbations during the last year” and “ED/hospital admissions.” Child asthma prevalence and exacerbations were analyzed using multivariable logistic regression, and HCU and total costs using generalized linear regression. We controlled for age, sex, race/ethnicity, income, insurance, asthma control, comorbid conditions, and each year of study data. We assessed asthma control using the ratio of quick relievers to total asthma medication (quick relievers+controllers).

Population Studied: The study population included child asthmatics age 5-17 years with TSE. Asthma prevalence was determined for all children age 5-17 years.

Principal Findings: Among the 8544 child asthmatics identified, 35.3% had TSE at home. Demographic characteristics of our samples were age (mean: 11.0±3.7 years), sex (41.1% female), and race/ethnicity (36.3% white, 30.0% black, 26.3% Hispanic, and 7.4% other).

Children living with more smokers were more likely to have asthma compared to children living with no smokers (1 smoker: OR=1.31, p<0.01; 2 smokers: OR=1.28, p<0.01; 3 smokers: OR=1.90, p<0.01). Compared to children living with no smokers, the likelihood of asthma exacerbations increased for children living with 2 (OR=1.42, p<0.01) or 3 smokers (OR=1.61, p=0.01). Children living with 2 (beta=0.24, p<0.01) or 3 (beta=0.32, p<0.01) smokers were more likely than children living with no smokers to have increased ED/hospital admissions. Estimated healthcare costs were higher for child asthmatics living with 1 ($212), 2 ($477), or 3 ($621) smokers compared child asthmatics living with no smokers.

Conclusions: Child asthma prevalence, exacerbations, HCU, and costs significantly increased with the number of smokers in the home.
Implications for Policy, Delivery, or Practice: The increased asthma morbidity and cost with increasing number of smokers in the home suggest effective interventions to reduce TSE among children with asthma are needed, including treating parental smoking. Other interventions include smoke free home rules, smoke free car laws, and other targeted policy interventions to reduce HCU and costs related to TSE among child asthmatics.

Childhood Health and Education: The Impact of Influenza at Different Ages on Education

Nolan Noble, University of Notre Dame

Presenter: Nolan Noble, M.A.,M.S.,B.A., PhD Student/NSF-IGERT Trainee, Department of Economics, University of Notre Dame, nnoble@nd.edu

Research Objective: This paper explores the latent effect of childhood health on educational attainment for a moderate ever-present shock. I estimate the effect of increased influenza virulence during childhood on educational outcomes.

Study Design: Influenza is a severe annual health threat to children, and virulence varies greatly across states and over time. This paper exploits this variation. I combine a large dataset from the Multiple Cause of Death (MCOD) files and the 1980, 1990, and 2000 US Censuses. This large dataset is examined using econometric analyses. Elderly influenza deaths are used as a proxy for influenza virulence. Outbreaks in influenza likely to affect children can be measured through elderly influenza mortality.

Population Studied: The US Census provides a random sampling of all individuals in the United States. This paper focuses on those individuals born between 1969 and 1977 for most educational attainment and health outcomes. Additionally, for individuals being currently progression on time during primary school and high school those born between 1969 and 1973 (for primary) and between 1970 and 1974 along with 1980 and 1984 (for high school).

Principal Findings: Individuals are 0.10–0.79 percentage points less likely to report higher levels of educational attainment due to influenza during the entirety of their childhood. High influenza virulence in early childhood (<6 years) works to increase educational attainment by 0.01–0.79 percentage points. Children exposed to influenza during the latter portion of primary school (3rd to 6th grade) have an average 0.14–0.97 percentage points decrease in educational attainment. There is also evidence that influenza at early ages increases the likelihood of permanent disabilities.

Conclusions: Overall influenza reduces schooling. However, immunity acquisition in children too young to attend school serves to increase their educational attainment. These gains are outweighed by losses suffered from influenza later in childhood. Individuals are 0.32%–1.85% less likely to report higher education when exposed to median influenza throughout childhood. This implies lost wages of $9.4–$37.4 billion.

A Systematic Approach to Screening for Adolescent Depression and Enhancing the Quality of Primary Care Depression Management and Monitoring

Ardis Olson, Geisel School of Medicine at Dartmouth; Susan Smiga MD, Geisel School of Medicine at Dartmouth; Rebecca Horvath RN, Geisel School of Medicine at Dartmouth; Louis Kazal MD, Geisel School of Medicine at Dartmouth; Deborah Johnson MHA, Geisel School of Medicine at Dartmouth

Presenter: Ardis Olson, MD, Professor of Pediatrics, Pediatrics/Community and Family Medicine, Geisel School of Medicine at Dartmouth, Ardis.L.Olson@dartmouth.edu

Research Objective: To describe the implementation of a new primary care multipractice system to identify youth depression, provide quality treatment and monitor outcomes to fulfill the US Preventive Services Task Force adolescent depression recommendations.

Study Design: The Teen Mental Health project provided primary care practice supports to
enhance primary care management skills, establishment of routine adolescent depression screening using the Columbia TeenScreen PHQ-9 adapted for Adolescents, and a centralized registry to provide feedback to practices about outcomes. New quality of care indicators were defined for adolescent depression screening, primary care treatment planning, and outcomes monitoring. Components of the quality improvement practice supports provided were: 1) training clinicians and staff in systematizing screening and skills for depression/suicide risk assessment and management; 2) offering centralized psychiatric consultation for clinicians; 3) tracking of outcomes with uniform measures within a centralized registry. **Population Studied:** 467 depression screen positive youth, detected after 4904 adolescents were screened at health visits. These youth were cared for by 50 clinicians within 13 diverse non-affiliated pediatric and family medicine practices in VT and NH. **Principal Findings:** 9.2% of youth screened PHQ9-A positive either on the basis of depressive symptoms (score of 11 or more) or suicidal risk. Of those screened positive 23.8% responded that in the past month they had serious thoughts about taking their life. More than half of positive youth (54.8%) were newly detected cases. The majority (77%) of teens/families agreed to follow up care/outcomes monitoring by the practice. The above findings did not differ significantly by gender except more males(41%) than females(28%) declined follow up. Registry data shows the following quality of care components were provided at the initial clinician visit: psycho-education (70%), guidance about mental health self care (65%), mental health counseling in place or new referral (81%), started or changed antidepressant medication (64%), discussed suicide safety plan (49%). 38% of youth identified as positive had a follow up visit within 8 weeks. Of these, 68% had a repeat PHQ-9A to assess course. No practices had a protocol for follow up or use of an objective measure to monitor progress prior to the project. All active practices established consistent screening routines, however there was considerable variation in establishing regular data entry into the registry. Pre-intervention practice readiness measures did not predict practice implementation differences. While all clinicians within these practices screened, depression care was more likely to be provided by female providers to female adolescents with the majority of care provided by a few individuals within each practice. Information will be provided comparing variation in screening, management, and use of the registry by electronic medical record status, primary care specialty, leadership and administrative facilitators and barriers. **Conclusions:** A multi-practice systems change approach with an external catalyst providing supports, has resulted in a change in practice culture to embrace adolescent depression screening and care as a part of the medical home. **Implications for Policy, Delivery, or Practice:** To expand the primary care medical home to address youth mental health issues it will require flexible timeline for implementation, external supports and identification of resources for maintaining routines and registries. **Funding Source(s):** AHRQ **Poster Session and Number:** A, #181 **Peer Social Networks Influence on Health and Education** Wendy Parker, Albany College of Pharmacy and Health Sciences; Rachel A. Smith, Baruch College **Presenter:** Wendy Parker, Ph.D., Assistant Professor Of Sociology, Arts and Sciences, Albany College of Pharmacy and Health Sciences, wmpc@mac.com **Research Objective:** To understand if a high school student’s health status is related to their position in their social network in high school. To determine if health is predictive of local and/or global social network status for US adolescents. In terms of education, can we explain how peer network relationships are connected to postsecondary attainment. **Study Design:** Using Wave I and Wave IV data from Add Health, we utilize constructed peer network measures in linear and logistic regression models to assess health, education and peer relationships. **Population Studied:** Add Health is a longitudinal, nationally representative sample of 90,118 adolescents in grades 7-12 attending 80 high schools and 50 middle schools in 1994-95. **Principal Findings:** Findings to date have shown for the health models: Health status is related to peer networks for adolescents. Adolescents in poorer health are a part of social
networks that: Have less centrality and have decreased proximity prestige (closeness); Have fewer both in and out degree ties; but have increased mutuality or mutual ties. For the education models: Results are mixed regarding the relationship between high school peer network status and whether a student goes on to any form of postsecondary education; High school peer network measures appear to be positive predictors of bachelor’s degree attainment or enrollment (vs. no college)

**Conclusions:** Adolescents who are in poorer health are not as well connected in the network and when they are it is to others who are also less well connected. Overall adolescents in poorer health have fewer friendship ties (in or out). Conversely adolescents in better health have more friendship ties (both in and out), are more closely connected to all those in the network, and are connected to more well connected adolescents.

**Implications for Policy, Delivery, or Practice:** If health and peer relationships are connected in high school, perhaps health behavior interventions can be focused on peer groups rather than just individuals to strive for better health outcomes.

If we can demonstrate connections between health and education at the relationship level for US adolescents, we can think about prevention and intervention packaging in a whole new way.

**Funding Source(s):** No Funding

**Poster Session and Number:** A, #182

---

**Research Objective:** Wide geographic variation exists in pediatric subspecialty supply in the US, prompting calls for change in recruitment and delivery of pediatric subspecialty care. It is not known, however, whether children in areas with decreased supply receive less subspecialty care or have worse health outcomes. Our objective was to compare pediatric subspecialty visits and health outcomes in states with high and low subspecialty supply.

**Study Design:** The 2009-10 National Survey of Children with Special Health Care Needs is a nationally-representative survey of children with chronic medical conditions. For the preceding year, parents reported subspecialty use and the following health outcomes: unmet subspecialty need, missed school days, emergency department visits, functional limitations, health information received, and perceived financial burden related to medical needs. Using the 2010 Area Resource File, states were grouped into quintiles of pediatric subspecialty supply per population. The associations between pediatric subspecialty supply, utilization, and outcomes were measured with both unadjusted analyses and multivariable logistic regression (adjusting for sociodemographic variables and primary care experience). Analyses accounted for population weights and survey design.

**Population Studied:** 40,242 children with one or more chronic medical condition.

**Principal Findings:** Nationally, 46% of children with a chronic medical condition reported a subspecialty visit in the prior year. In unadjusted results, 49% of children in states with highest quintile of supply reported seeing a subspecialist compared to 41% of children in states with lowest quintile of supply (p<0.001). In our multivariable model, compared to children in states with highest subspecialty supply, children in states with lowest subspecialty supply were less likely (OR 0.75, 95% CI 0.67-0.85) to have seen a subspecialist in the preceding year. Children in states with lowest supply were more likely to have increased unmet subspecialty need (11%, compared to 7% in states with highest supply, p<0.001) and increased illness-related financial burden (23%, compared to 18% in areas of highest supply, p<0.001), but subspecialty supply was not associated with significant differences in the other examined health outcomes.

**Conclusions:** Children with chronic medical conditions in states with lower pediatric subspecialty supply were less likely to receive subspecialty care and more likely to report...
unmet subspecialty need. However, lower subspecialty supply was not associated with differences in most health outcomes, including missed school days, emergency department visits, functional limitations, and receipt of adequate health information.

Implications for Policy, Delivery, or Practice: Policies to address the maldistribution of pediatric subspecialists or to expand the geographic reach of current pediatric subspecialists (such as telemedicine) may help improve access to pediatric subspecialists and reduce reported unmet need. However, further research will be necessary to determine whether such strategies actually improve health outcomes.

Trends in Pediatric Quality Indicators for Outpatient Care, 2007-2011
John Richardson, Truven Health Analytics; Mark W. Smith, Truven Health Analytics

Presenter: John Richardson, M.P.H., Senior Analyst, Truven Health Analytics, john.richardson@truvenhealth.com

Research Objective: Examine the trends in pediatric quality indicators for outpatient care.

Study Design: A retrospective claims analysis examined compliance with 16 quality indicators among commercially insured children from 2007 to 2011. The indicators pertained to the outpatient treatment of both acute and chronic health conditions: common cold, otitis media, concussion, asthma, diabetes, depression, eczema, and migraines. We examined the results altogether and by sex. We also used a Cochrane-Armitage test to identify significant linear trends over time.

Population Studied: Outpatient records of children ages 0 to 17 were analyzed using the Truven Health MarketScan Commercial Claims and Encounters Database. The database includes medical claims from large employers and health plans across the United States that provide private healthcare coverage for more than 20 million employees, spouses, and dependents each year.

Principal Findings: We found a significant positive trend in the quality of outpatient treatment provided for the common cold, otitis media, diabetes, depression, and eczema. All but the treatment examined for otitis media also had more than a 2.5 percentage point increase or the total percentage point increase accounted for more than a 5 percent reduction in the quality gap. For asthma, three indicators had a significant positive trend (proper use of controller medications, use of inhaled corticosteroids, and receiving the flu shot), but two indicators had a significant negative trend (no emergency department visit among young children, and having four office visits in two years). There was a small but significant negative trend in providing a CT scan to children with a concussion (-0.8 percentage point difference, p less than 0.0001). We found no significant change in the quality of care for migraines. Six of 16 quality indicators had less than 50 percent compliance each year. Among males, the largest increases in quality were in providing flu shots to children with asthma (7.2 percentage point increase), HbA1c testing for diabetes (5.9 percentage points), calcineurin inhibitors not as a first line of treatment for eczema (5.1 percentage points), and monitoring during the first six months of treatment for depression (4.7 percentage points). Among females, the largest increases in quality were in lipid profiling for diabetes (6.8 percentage point increase), providing flu shots for children with asthma (6.7 percentage points), and HbA1c testing for diabetes (5.3 percentage points).

Conclusions: Outpatient care for children has been improving for the majority of the selected acute and chronic conditions in this study. Even with these increases, however, in many cases fewer than half of children receive high-quality treatment.

Implications for Policy, Delivery, or Practice: Quality reform will need to continue to address relatively low rates of compliance. Where electronic health records are not available, outpatient claims can be used as a means to monitor trends in the quality of pediatric care over time.

Poster Session and Number: A, #184

Outcomes of Co-Management, an Innovative Care Model
Karen Rubin, Connecticut Children's Medical Center; Eminet Abebe Feyissa, MPH, Connecticut Children's Medical Center; Erin Cornell, MPH, Connecticut Children's Medical Center; Cristian Ionita, MD, Connecticut Children's Medical Center; David Wang, MD, Connecticut Children's Medical Center; Regina
Kostyun, MS.Ed ATC, Connecticut Children's Medical Center; Jennifer Schwab, MD, FAAP, University of Connecticut School of Medicine

**Presenter:** Karen Rubin, M.D., Associate Clinical Chair Of Pediatrics, Endocrinology, Connecticut Children's Medical Center, krubin@ccmckids.org

**Research Objective:** The main objective of the study was to expand on earlier findings which demonstrated the feasibility of implementing Co-Management, an innovative model of care, in the primary care setting. Using this model, teams consisting of a primary care provider (PCP) and one or more subspecialists developed a set of tools for management of relatively common pediatric conditions such as concussion. The study aimed to assess broad outcomes, including the potential of the model to minimize variation and enhance the quality of care, reduce unnecessary referrals and testing, and potentially reduce system level cost. Provider satisfaction was also measured.

**Study Design:** Co-managed patients who were prospectively enrolled were compared to a retrospective audit of demographically comparable, non-co-managed patients with the same condition from the same practice.

**Population Studied:** All patients with suspected concussion aged 3-18 years at a suburban practice were eligible. Nine PCPs, including 7 MDs and 2 APRNs, participated.

**Principal Findings:** Eighty-three patients with suspected or confirmed concussion were enrolled by 9 PCPs, resulting in a total of 205 Co-Management visits. Co-Management enhanced the quality of care as demonstrated by PCPs’ adherence to the consensus-based algorithm: 98% of co-managed patients had at least one top symptom identified by the PCP; all had the diagnosis (concussion or other) identified and confirmed using the Co-Management tools; and 98% had at least one recommended treatment option (e.g. rest, level of activity) identified. All PCPs stated that they are very or somewhat satisfied with Co-Management as a model of care.

Eighty-eight percent of co-managed patients had at least one follow-up visit scheduled with the PCP compared to 75% in the control group (n=20). In the co-managed group, 92% of patients were exclusively managed by the PCP and 8% were referred to subspecialist care compared to 85% and 15% in the non-co-managed group. Seventy-one percent of the Co-Management referrals (n=7) were appropriate according to the Co-Management algorithm.

Billing data, obtained for 165 Co-Management and 45 non-Co-Management office visits, showed that 82% were billed as level 4 or 5 visits in the co-managed group compared to 56% in the control group (p = 0.001).

**Conclusions:** The findings indicate that Co-Management of concussion can enhance the quality of care by demonstrating adherence to a consensus-based algorithm. The results also support the feasibility of building PCP capacity to enable more independent management of care for patients with relatively common pediatric conditions. The level of provider satisfaction with the model adds to the evidence of feasibility. That PCPs billed Co-Management office visits at higher levels compared to non-Co-Management visits suggests that the model can divert the care of less complex patients from expensive ED or subspecialist settings to primary care, potentially reducing system-level costs.

**Implications for Policy, Delivery, or Practice:** The Co-Management model is particularly timely in the current health care context as it is a valuable resource for the implementation of the patient-centered medical home and accountable care. Model scalability, possible with an investment in a Co-Management infrastructure and the alignment of provider incentives, has the potential to significantly improve the quality of care and reduce unnecessary costs.

**Variation in Adverse Perinatal Outcomes among Asians and Pacific Islanders in Hawaii**

Tetine Sentell, University of Hawaii at Manoa; Hyeong Jun Ahn, Biostatistics Core, University of Hawaii John A. Burns School of Medicine; Ann Lee Chang, Obstetrics, Gynecology, and Women's Health, University of Hawaii John A. Burns School of Medicine; Jill Miyamura, Hawaii Health Information Corporation

**Presenter:** Tetine Sentell, Ph.D., Assistant Professor, Office of Public Health Studies, University of Hawaii at Manoa, tsentell@hawaii.edu

**Research Objective:** Empirical evidence regarding adverse perinatal outcomes across
heterogeneous Asian and Pacific Islander subgroups is limited, despite the importance of this topic to health disparities research and quality improvement efforts.

**Study Design:** Detailed discharge data from all Hawaii childbirth hospitalizations from January 2008 to June 2012 were used. Outcomes considered were preterm delivery (defined from MS DRG), low birth weight (less than 2500g), and macrosomia (greater than 4000g) as well as an AHRQ patient safety indicator: birth trauma, injury to neonate (using AHRQ guidelines). Outcomes were compared in descriptive and multivariable models across seven maternal racial/ethnic groups: Filipinos, Hawaiians, other Pacific Islanders (e.g., Samoan, Tongan, Micronesians), Japanese, Chinese, White, and other race/ethnicity. Multivariable Poisson regression models estimated rate ratios (RR) with 95 percent confidence intervals (CI) adjusting for maternal age group, payer, rural vs. urban hospital location, high-risk pregnancy, and multiple gestation.

**Population Studied:** A total of 65,817 childbirth hospitalizations out of 73,123 maternal-related hospitalizations were considered. Total maternal-related hospitalizations were 23 percent Native Hawaiian, 20 percent Filipino, 19 percent White, 13 percent other race/ethnicity, 11 percent other Pacific Islanders, 10 percent Japanese, and 3 percent Chinese. Age group, payer, hospital location, multiple gestation, and high-risk pregnancies varied significantly across race/ethnicity.

**Principal Findings:** In multivariable models, Filipinos (RR: 1.69; CI: 1.53-1.87), other Pacific Islanders (RR: 1.25; CI: 1.11-1.40), Native Hawaiians (RR: 1.24; CI: 1.12-1.38), and Japanese (RR: 1.22; CI: 1.08-1.38) had significantly higher rates of preterm deliveries than Whites. For low birth weight, Filipinos (RR: 1.83; CI: 1.67-2.01), Japanese (RR: 1.57; CI: 1.40-1.75), and Native Hawaiians (RR: 1.22; CI: 1.11-1.35) all had significantly higher rates than Whites. All racial/ethnic groups had significantly lower rates of macrosomia than Whites except for other Pacific Islanders who did not vary significantly from Whites; RR for macrosomia ranged from 0.86 among Hawaiians to 0.34 among Filipinas. Birth trauma, injury to neonate, was significantly less for both Hawaiians (RR: 0.67; CI: 0.45-0.99) and Japanese (RR: 0.56; CI: 0.34-0.94) compared to Whites, but did not differ significantly for other racial/ethnic groups.

**Conclusions:** Patterns in adverse perinatal outcomes vary across Asian and Pacific Islanders subgroups, revealing distinct patterns of clinical interest. For instance, Chinese did not report any poor newborn outcomes, while Filipinos had the highest rates of preterm deliveries and low birth weight. These important differences would likely be hidden in combined Asian and Pacific Islander analyses. Also, analyses did not reveal typical patterns of perinatal outcome disparities with Whites, for instance, having higher rates of macrosomia and birth trauma compared to Native Hawaiians.

**Implications for Policy, Delivery, or Practice:** Asian and Pacific Islanders subgroups must be disaggregated to understand clinical patterns, to identify possible disparities, and to design effective interventions.

**Pediatricians and Bullying: Parent and Community Perspectives on the Pediatrician's Role in Screening, Prevention, and Intervention**

Rashmi Shetgiri, University of Texas Southwestern Medical Center and Children's Medical Center; Blanca Villasenor, BA, University of Texas Southwestern Medical Center; Glenn Flores, MD, University of Texas Medical Center and Children's Medical Center

**Presenter:** Rashmi Shetgiri, M.D., M.S.H.S., Assistant Professor of Pediatrics, Pediatrics, Division of General Pediatrics, University of Texas Southwestern Medical Center and Children's Medical Center, rashmi.shetgiri@utsouthwestern.edu

**Research Objective:** Bullying affects 30% of US children. The American Academy of Pediatrics recommends that pediatricians address bullying with children and families, but not enough is known about what specific role pediatricians might play. The objective was to identify parental and community perspectives on pediatricians' role in identifying bullying, improving Bright Futures bullying-related materials, and primary-care-based bullying-prevention strategies.

**Study Design:** Six focus groups and 16 semi-structured interviews were conducted with parents, stratified by the child's bullying (bully, both bully and victim, victim, or uninvolved); 2 interviews were conducted with school administrators and 6 with leaders of community-based organizations (CBOs). Fourteen questions were asked in 4 domains. Sessions
were audiotaped, transcribed, and analyzed using margin coding and grounded theory. Themes were independently identified by 3 coders, with disagreements resolved by consensus.

**Population Studied:** Parents of children 5-17 years old, and school and community leaders.

**Principal Findings:** The 51 participants included 43 parents and 8 key informants. Parents stated that pediatricians can identify bullying by asking children questions such as “does anybody at school tease you?” Parental denial was cited as a challenge, with victims’ parents “not believing it is as bad” and parents of bullies resistant, as “nobody wants to believe your kid is doing that.” Bullying-prevention strategies cited included educating children and parents about effects of bullying, and providing counseling. Bright Futures materials could be more effective by having doctors review questionnaires with parents, using materials as tools to guide discussion, and providing brochures and DVDs. Parents of victims and bully-victims stated that pediatricians could complement community bullying-prevention activities by working with schools: “if they have a kid they are concerned about, they can let the school counselor know, so they can be on the lookout for that child.” Parents of bullies stated that reporting bullying to teachers is not helpful; encouraging children to defend themselves was viewed as preferable. Key informants stated that pediatricians should be more involved in bullying prevention, audiovisual materials should be provided and reviewed with parents, and doctors should contact schools when bullying is suspected. School administrators cited student confidentiality as a potential barrier to working with pediatricians. CBO leaders suggested that pediatricians should make contacts with community organizations.

**Conclusions:** Parents and key informants stated that pediatricians can play essential roles in identifying and preventing bullying. Pediatricians can identify bullying by asking children whether they are being teased at school. Bullying-prevention strategies include the use of Bright Futures materials to discuss bullying, providing brochures and DVDs, educating families about the effects of bullying, and providing counseling. Parents of bullies encouraged children to defend themselves. Parents and key informants recommended working with schools to prevent bullying.

**Implications for Policy, Delivery, or Practice:** The study results could be used to improve pediatricians’ bullying-prevention practices. Use of written and audiovisual formats of Bright Futures materials might improve patient education about bullying. It may prove useful for pediatricians to work closely with schools and community organizations to monitor and intervene with bullies and victims and jointly advocate for bullying-related prevention and counseling policies.

**Quality of Outpatient Care in 2010 for Children with Medicaid or Commercial Insurance**

Mark W. Smith, Truven Health Analytics; John Richardson, Truven Health Analytics

**Presenter:** Mark Smith, Ph.D., Director, Truven Health Analytics, mark.w.smith@truvenhealth.com

**Research Objective:** To compare the quality of outpatient care received by children in Medicaid and those with commercial private insurance.

**Study Design:** This was a retrospective analysis of administrative insurance claims. Fifteen quality indicators were identified in four acute and four chronic health conditions. Indicator definitions were applied to a pair of large claims databases. The percentages of children meeting the standards of care were calculated within each insurance category (private or Medicaid) overall and by sex and age group.

**Population Studied:** Children ages 0-17 whose claims appear in the 2010 Truven Health MarketScan Commercial Claims Database and the Truven Health MarketScan Multi-State Medicaid Database.

**Principal Findings:** Children in Medicaid were significantly more likely to receive 7 types of high-quality care, of which 6 had clinically meaningful differences: recommended antibiotics for otitis media (67.4% vs. 61.2%), no antibiotics for the common cold (92.0% vs. 88.8%), proper controller medications for asthma (93.6% vs. 90.4%), retinal exam for diabetes (57.8% vs. 28.8%), lipid profiling for diabetes (45.5% vs. 40.4%), and calcineurin inhibitors only as a second line of treatment for eczema (61.3% vs. 48.2%). Commercially insured children fared better on 8 indicators on average, always by a clinically meaningful amount: inhaled corticosteroids for asthma.
(49.9% vs. 47.6%), influenza vaccination for those with asthma (36.1% vs. 25.3%), HbA1c testing for diabetes (64.1% vs. 55.2%), microalbumin testing for diabetes (38.0% vs. 32.3%), monitoring during the first six months of treatment for depression (64.2% vs. 59.5%), and at least six months of medication for major depression (61.0% vs. 57.3%). For the treatment of depression, the disparities were primarily among females. Differences were consistent across age groups, although for nearly half of the quality indicators compliance for both the Medicaid and commercial insurance populations decreased with age.

Conclusions: Medicaid providers are closing the quality gap: while many earlier studies have found private insurance to provide better-quality care, in 2010 we find that children in Medicaid were about as likely to receive high-quality outpatient care in 2010 as were privately insured children. Regardless of insurance type, however, high-quality outpatient care for both acute and chronic conditions is often not provided.

Implications for Policy, Delivery, or Practice: The Medicaid program manages to provide ambulatory care roughly similar to that of private insurance despite a smaller pool of providers and a population that faces many barriers to obtaining care. The striking disparities between publicly and privately insured children on certain indicators deserve exploration. Overall, a considerable effort would be needed to achieve even 80% compliance on each of these indicators.

Adolescent Self-Report of Patient-Centered Care: Association with Receipt of High Quality Primary Care and Unmet Needs
Sara Toomey, Children's Hospital Boston; Marc N. Elliott, PhD, RAND Corp; David C. Schwebel, PhD, Psychology Department, University of Alabama at Birmingham; Paula M. Cuccaro, PhD, Center for Health Promotion and Prevention Research, University of Texas School of Public Health; Susan R. Tortolero, PhD, Center for Health Promotion and Prevention Research, University of Texas School of Public Health; Susan L. Davies, PhD, Department of Health Behavior, University of Alabama at Birmingham; Vinay Kampalath, BA, Boston Children’s Hospital; Mark A. Schuster, MD, PhD, Boston Children’s Hospital, Harvard Medical School

Presenter: Sara Toomey, M.D., M.P.H., M.Phil., Instructor, Division of General Pediatrics, Children's Hospital Boston, sara.toomey@childrens.harvard.edu

Research Objective: To examine whether patient characteristics are associated with adolescent self-report of patient-centered care (PCC) and whether adolescent receipt of PCC is associated with characteristics of high-quality primary care and fewer unmet needs.

Study Design: We conducted a cross-sectional analysis of a representative sample of adolescents. The main outcome was adolescent report of PCC. PCC was derived as a dichotomous variable from four key components of patient-centeredness. Specifically, they are asked if their doctors or health providers listened carefully to them, explained things in a way that was easy to understand, showed respect for what they said, and spent enough time with them. To meet criteria for receipt of patient-centered care, an adolescent reported that his/her doctor or health provider “usually” or “always” performed each of these four activities over the last 12 months. Markers of high-quality adolescent primary care included access to private conversations and having health providers who discussed health behaviors and screened for risk behaviors. Health-related outcomes included self-report of global health status, quality of life (PedsQL), and unmet need. Additional covariates included gender, race/ethnicity, insurance status, highest household education, household income, research site, and children with special health care needs (CSHON) status. We conducted weighted bivariate and multivariate analyses.

Population Studied: The analysis includes a representative sample of 5,147 10th graders and their parents in three U.S. metropolitan areas.

Principal Findings: Fifty-nine percent of adolescents reported that they received PCC. Adolescent report of PCC differed by race/ethnicity: Asian (46%), Black (53%), Hispanic (45%), and White (58%, p<0.001). Adolescent report of PCC also differed by insurance status: adolescents with private insurance (58%), with public insurance (45%), and without insurance (47%, p<0.001). Adolescents with better health status were more likely to report PCC (Excellent 58%, Very good 55%, Good 45%, Fair/Poor 43%; p<0.001). Report of PCC was associated with markers of high quality adolescent primary care and fewer

Principal Findings: Fifty-nine percent of adolescents reported that they received PCC. Adolescent report of PCC differed by race/ethnicity: Asian (46%), Black (53%), Hispanic (45%), and White (58%, p<0.001). Adolescent report of PCC also differed by insurance status: adolescents with private insurance (58%), with public insurance (45%), and without insurance (47%, p<0.001). Adolescents with better health status were more likely to report PCC (Excellent 58%, Very good 55%, Good 45%, Fair/Poor 43%; p<0.001). Report of PCC was associated with markers of high quality adolescent primary care and fewer
Implications for Policy, Delivery, or Practice: PCC is a defining element of the patient-centered medical home. Few studies have examined adolescents’ reports of having received PCC. Demonstrating that adolescents’ report of PCC is associated with markers of high quality primary care and fewer unmet needs provides support for asking adolescents directly about whether they receive PCC as a measure of the quality of adolescent primary care.

Birth Complications and Neonatal Readmissions: Trends 2002-2009, Payers and Major Diagnoses
Tara Trudnak, AcademyHealth; Gerry Fairbrother, PhD, AcademyHealth; Pamela Owens, PhD, Agency for Healthcare Research and Quality; Lisa Simpson, MB, BCh, MPH, FAAP, AcademyHealth

Presenter: Tara Trudnak, Ph.D., MPH, Senior Research Manager, AcademyHealth, tara.trudnak@academyhealth.org

Research Objective: The objectives of this paper are 1) to examine overall trends and trends in payer types of complicated births and 30-day neonatal readmissions from 2002 through 2009, 2) to describe most common diagnoses associated with complicated births and readmissions, and 3) to determine most likely payer type for these diagnoses.

Study Design: Data from 2002-2009 were examined from the Healthcare Cost and Utilization Project (HCUP), Nationwide Inpatient Sample (NIS). Diagnoses were identified using all listed ICD-9-CM classifications and categorized using the Clinical Classifications Software (CCS). The most prevalent diagnoses for complicated births and 30-day readmissions were ascertained. Analysis included a chi-square test for trend to assess differences over time, and a logistic regression to determine likely payer source (Medicaid, Private or Uninsured) for the most prevalent diagnoses. Odds ratios were adjusted for infant’s gender, race/ethnicity and hospital characteristics.

Population Studied: Newborns with diagnosis other than live birth (complicated birth), and readmissions that occurred within 30 days of birth.

Principal Findings: All payer hospital discharge, average costs and average length of stay for complicated births and 30-day hospital readmissions showed a trend toward increasing from 2002 to 2009, but did not reach statistical significance (p=.08). In 2009, there were 859,853 discharges for complicated births and 30-day readmissions with an average cost per discharge of over $13,000. The proportion of complicated births and neonatal readmissions paid for with private insurance decreased substantially from 2002 to 2009 (p<.0001), while the proportion paid for by Medicaid substantially increased (p<.0001). By 2008 Medicaid was paying for more complications and readmissions than private insurance.

Among complicated births, the most prevalent diagnoses in 2009 were preterm birth/low birthweight (23%), followed by respiratory distress (18%) and jaundice (10%). Preterm birth/low birth weight and respiratory distress together (41.3% of the neonates) account for 61% of the aggregate cost with almost the same mean length of stay of about 14 days. Compared to private insurance, Medicaid paid for more preterm/low birthweight (p<.0001) and respiratory distress (p<.005) complications, whereas private insurance paid for more 30-day readmissions for jaundice relative to Medicaid (p<.006).

Conclusions: This study found an overall increase in hospital discharges for complicated births and 30-day readmissions from 2002 to 2009. Most strikingly, over time, the number of complicated birth/30-day readmissions paid for by Medicaid increased, while the number paid for by private payers decreased.

Implications for Policy, Delivery, or Practice: Policies to prevent some of the high-cost birth complications have the potential for both reducing costs as well as improving birth outcomes.

Poster Session and Number: A, #190
The Joint Influence of Individual Choices and Family Characteristics on Youth Obesity: A Latent Class Analysis
Hongmei Wang, University of Nebraska Medical Center, College of Public Health; Junyoon Kim, UNMC; Liyan Xu, Creighton University

Presenter: Hongmei Wang, PhD, Assistant Professor, Health Services Research, University of Nebraska Medical Center, College of Public Health, hongmeiwang@unmc.edu

Research Objective: Over the last three decades, obesity has reached epidemic proportions among children in the United States. Studies suggest that individual physical activity and eating behavior choices, parent control, and advising of primary care providers are factors related to youth overweight status and weight control efforts. However, few studies have examined how the combination of these factors will impact the youth overweight status. This study aims to gain a deeper understanding on the joint influence of these factors on youth overweight status using a Latent Class Analysis method to inform policy interventions targeting the epidemic of youth obesity.

Study Design: The authors of this paper utilize survey data for youth aged 12 to 19 years in a Midwest city to examine the joint effects of individual behavior choices, family background, and physicians advice on youth weight status. The survey was conducted by phone in Fall 2008 to collect information on weight status, weight control methods, physical activity, dietary behaviors, parenting style, and physician's advising of local youth. The final sample of the survey contained 894 responses with a total response rate of 37.5%. A latent-class analysis was conducted to group the youths based on four factors: physical activity, dietary behaviors, parenting style, and physician's advice on obesity. A logistic regression was followed to examine the relationship of these groups to the weight status of the youth to examine the joint influence of the four factors on youth weight status.

Population Studied: The target population is youth aged 12 to 19 years that resided in the county. African American and Hispanic youth were over-sampled to produce estimates for these groups with adequate precision.

Principal Findings: LCA analysis returned three groups of youth, with Group I representing youth with good physical activity and eating behavior, parental control, and physician advice; Group II representing youth with good physical activity and eating behavior, parental control, but without physician advice; Group III representing youth not with healthy eating and physical activity and eating behaviors, permissive parenting, and physician advice. The logistic regression results suggest that youth in Group I are less likely to be overweight than youth in Group III (OR=2.54). Similarly, youth in Group II are less likely to be overweight than youth in the third group (OR=2.92).

Conclusions: Logistic regression results suggest that healthier individual behaviors and tighter parental control together may have prevented youth from getting overweight. Interestingly, we don’t observe a stronger preventive effect from Group I than Group II, which suggest that whether physicians provide advice during the youth’s wellness check up visit on physical activity and nutrition actually don’t have any significant influence on the weight status of youth.

Implications for Policy, Delivery, or Practice: The study results suggest that policies targeting reducing youth obesity should consider a combination of interventions at different levels to be most effective. Additionally, the study results suggest primary care physicians' involvement needs to be more in-depth and comprehensive to make an impact on prevention of youth overweight.

Antipsychotic Use among Medicaid Children in Eight States
Daniel Weinberg, IMPAQ International, LLC; Norma Gavin, RTI International

Presenter: Daniel Weinberg, Ph.D., Research Associate Economist, IMPAQ International, LLC, dweinberg@impaqint.com

Research Objective: According to multiple studies, utilization of atypical antipsychotic drugs (AAPs) has increased substantially in recent years, and this trend is also present among vulnerable populations. We examine the use of AAPs and first generation antipsychotics (FGAPs) among Medicaid children to ascertain which drugs are most commonly prescribed and the age, race/ethnicity, gender, and eligibility groups to which they are prescribed. We also examine longitudinal trends and consider the
consistency of utilization patterns across study states.

**Study Design:** We use the Environmental Scanning and Program Characteristics (ESPC) Database (a CMS-sponsored database containing state-level data on Medicaid program characteristics) and other relevant data to select study states having complete prescription drug claims data. We consider the following criteria: enrollment in comprehensive managed care; proportion of full-benefit fee-for-service (FFS) child enrollees with prescription drug claims; and average FFS drug spending per full-benefit FFS child enrollee. We combine MAX person summary and prescription drug files to produce analytic files for the analyses, and use the FirstDataBank prescription drug crosswalk to identify NDC codes for AAPs and FGAPs.

**Population Studied:** All individuals aged less than one year to 20 years in Alabama, Colorado, Iowa, Illinois, Louisiana, North Carolina, New Hampshire, and Oklahoma who were non-dua Medicaid-eligibles for at least eight months during the study years, 2005-2008.

**Principal Findings:** Utilization rates are defined as the number of children per thousand who had at least one prescription fill (either new prescriptions or refills) for the drug under study. Overall antipsychotic (AP) utilization rates range from 17/1000-31/1000 prescription fills. Across all study states, AP utilization increased from 20.9 fills per 1,000 children in 2005 to 23.3 in 2008 (an increase of 11.4 percent). Between 2.4/1000 and 5/1000 children have fills for two distinct AP drugs; between 0.5 and 1.1 have fills for three or four unique AP drugs, and very few children, 0.01 per thousand (179 children in our sample) have five or more prescription fills for distinct APs.

Patterns in AP utilization are remarkably similar across study states. FGAPs account for a small proportion of AP utilization (range: 0.03/1000-0.12/1000). Risperidone is the most prescribed AAP in seven of the eight states (range: 8.5/1000-13.7/1000), followed by quetiapine (range: 3.7/1000-13.7/1000) and aripiprazole (range: 3.7/1000-10.0/1000). In all but one state, 15-17 year-olds have the highest AP utilization rates (range: 30.2/1000-83.5/1000) followed by 12-14 year-olds. In all states, infants have the lowest AP utilization rates (range: 0.02/1000-0.12/1000). Males' AP utilization rates (range: 22.5/1000-53.8/1000) are approximately twice those of females (range: 10.5/1000-25.4/1000). In six study states, Whites have the highest AP utilization rates (range: 23.9/1000-52.9/1000) while Asians and Hispanics have the lowest. Children in the foster and blind/disabled eligibility groups have the highest AP utilization rates (range: 89.7/1000-171.0/1000 and 100.8/1000-206.5/1000 for foster and blind/disabled, respectively) in comparison to the other eligibility groups (1931, poverty, medically needy, other).

**Conclusions:** The utilization patterns observed in this study are robust across study states and provide additional evidence that AAP utilization is increasing among Medicaid children. More research is necessary to understand why utilization is increasing among this vulnerable population.

**Implications for Policy, Delivery, or Practice:**

**Access to Needed Mental Health Care Among Children with Special Needs and their Families: Do Medical Homes Matter?**

Wendy Weller, SUNY Albany SPH

**Presenter:** Wendy Weller, Ph.D., Associate Professor, Health Policy, Management and Behavior, SUNY Albany School of Public Health, wweller@albany.edu

**Research Objective:** The purpose of this study is to examine the relationship between having a quality medical home and unmet mental health care need among children with special health care needs (CSHCN) and their families.

**Study Design:** This is a cross-sectional study using data from the 2009-2010 National Survey of Children with Special Health Care Needs (NS-CSHCN). Multivariable logistic regression models were used to assess the association between having a medical home and unmet mental health need for CSHCN and family members after controlling for sociodemographic and health characteristics. Models were constructed for an overall medical home composite measure as well as for each of the five component elements of the medical home (usual source of care, personal physician or nurse, family-centered care, receipt of needed referrals, and effective care coordination).

Additional analyses, stratified by presence of a chronic emotional, behavioral, or developmental problem (EBDP), were conducted to examine if the effect of having a medical home on mental health service access differed for children with and without a chronic EBDP.
Population Studied: The study population included CSHCN (n=10,620) and family members of CSHCN (n=4,232) who were reported to need mental health care services.

Principal Findings: The adjusted odds for unmet mental health care need were significantly higher for CSHCN who did not have a medical home compared to those with a medical home (adjusted odds ratio [OR]: 2.95; 95 percent confidence interval [CI]: 2.19-3.97); similar results were obtained for family members (adjusted OR: 3.80; 95 percent CI: 2.54-5.76). Each of the five component elements of the medical home was significantly associated with unmet mental health care need for CSHCN; children who lacked a given medical home element were more likely to have an unmet mental health care need. Among family members of CSHCN, three of the five medical home elements were significantly associated with unmet mental health care need: family-centered care, receipt of needed referrals, and effective care coordination. Children with and without a chronic EBDP without a medical home were significantly more likely to have an unmet mental health care need. While each of the five medical home elements was significantly associated with unmet mental health care need for CSHCN with a chronic EBDP, only two were significantly more likely to be associated with an unmet mental health care need for CSHCN without a chronic EBDP (received needed referrals and effective care coordination).

Conclusions: CSHCN and their families are more likely to experience an unmet need for mental health care if the child does not have a medical home.

Implications for Policy, Delivery, or Practice: Medical home access for CSHCN with mental health care needs is important for linking both children and their families with needed mental health services. Ensuring that medical homes provide family-centered care, effective care coordination, and needed referrals, may be particularly important for guaranteeing that CSHCN and their families receive the mental health care services they need.

Funding Source(s): No funding

Research Objective: Breastfeeding confers important health benefits for very preterm infants and facilitates maternal-child bonding. Establishing breastfeeding in the neonatal intensive care unit (NICU) is complex, and mothers may need to pump milk frequently for long periods before the baby can nurse. Following an international survey showing wide variation of breastfeeding rates for very preterm babies between European regions (from 20% to over 80%), we aimed to identify organisational and policy factors in the NICU that could explain this variation.

Study Design: Face-to-face, semi-structural interviews were conducted with health care providers in four NICUs in three European regions with different breastfeeding rates: Ile-de-France, France (low), Trent, UK (medium) and Lazio, Italy (high). Verbatim transcripts were coded using a theoretical framework derived from the literature on guideline implementation. Regional-level differences were analysed for practices related to breastfeeding initiation, management of breast milk and breastfeeding continuation/maintenance.

Population Studied: Interviews were held with the health professional(s) within the NICU with the most knowledge about the unit’s breastfeeding policy (lactation consultants (n=7), nurses (n=8), and doctors (n=7)). Tertiary units were purposively selected to reflect a range of breastfeeding rates and geographic and socio-cultural contexts within each region.

Principal Findings: The way health professionals approach mothers to start lactation differed by region. In the UK region, emphasis

Differences in Breastfeeding Management in Neonatal Intensive Care Units: A Cross-Country Qualitative Study

Research Objective: Breastfeeding confers important health benefits for very preterm infants and facilitates maternal-child bonding. Establishing breastfeeding in the neonatal intensive care unit (NICU) is complex, and mothers may need to pump milk frequently for long periods before the baby can nurse. Following an international survey showing wide variation of breastfeeding rates for very preterm babies between European regions (from 20% to over 80%), we aimed to identify organisational and policy factors in the NICU that could explain this variation.

Study Design: Face-to-face, semi-structural interviews were conducted with health care providers in four NICUs in three European regions with different breastfeeding rates: Ile-de-France, France (low), Trent, UK (medium) and Lazio, Italy (high). Verbatim transcripts were coded using a theoretical framework derived from the literature on guideline implementation. Regional-level differences were analysed for practices related to breastfeeding initiation, management of breast milk and breastfeeding continuation/maintenance.

Population Studied: Interviews were held with the health professional(s) within the NICU with the most knowledge about the unit’s breastfeeding policy (lactation consultants (n=7), nurses (n=8), and doctors (n=7)). Tertiary units were purposively selected to reflect a range of breastfeeding rates and geographic and socio-cultural contexts within each region.

Principal Findings: The way health professionals approach mothers to start lactation differed by region. In the UK region, emphasis
was placed on the value of breast milk for the preterm infant and health professionals expressed high efficacy related to their ability to convince mothers to initiate expression. In contrast, French personnel were concerned with allowing maternal choice and avoiding guilt about not breastfeeding. In Lazio, there was a strong expectation that all women would provide milk and breastfeed because of the importance for mother-infant bonding. Informants in all regions felt that the use of fresh milk facilitated breastfeeding and enhanced maternal motivation; however, respondents in Ile-de-France were also concerned with the health risks associated with the use of fresh milk and HCMV transmission and bacterial contamination. French and British personnel cited multiple patient and services obstacles to maintaining lactation and putting babies to the breast. In the Italian region emphasis was placed on putting the infant to the breast as soon as possible and on the normalizing effect of breastfeeding on the maternal-child relationship after a preterm birth.

**Conclusions:** Regions with higher breastfeeding rates highlighted the importance of breastfeeding for maternal-child bonding and the benefits of fresh breast milk and had less complex practices for managing mother's milk. Personnel in the French region where rates were lowest were more attuned to the potential infectious risks of breastfeeding, had more complex procedures for breast milk donation and expressed concerns about the difficulties that breastfeeding could entail for mothers.

**Implications for Policy, Delivery, or Practice:** Recommendations to promote breastfeeding in the NICU tend to focus on technical aspects related to personnel training, lactation and breastfeeding establishment. Integrating country-specific beliefs about the advantages and disadvantages of breastfeeding may improve the effectiveness of these recommendations. Information on the management of breastfeeding in other countries may be valuable for units trying to improve breastfeeding rates in this high risk population. Reference 1. Bonet et al. **Enhanced Access Services in Pediatric Primary Care and Emergency Department Utilization**

Joseph Zickafoose, Mathematica Policy Research; Lisa R. DeCamp, MD, MSPH, Division of General Pediatrics, Johns Hopkins University, Baltimore, MD, United States; Lisa A. Prosser, PhD, MS, Child Health Evaluation and Research (CHEAR) Unit, Division of General Pediatrics, University of Michigan, Ann Arbor, MI, United States

**Presenter:** Joseph Zickafoose, M.D., M.S., Researcher, Mathematica Policy Research, jzickafoose@mathematica-mpr.com

**Research Objective:** 1) To measure the prevalence of enhanced access services in pediatric primary care, and 2) to evaluate associations between enhanced access services and ED use.

**Study Design:** Internet-based cross-sectional survey. Parents were asked about enhanced access services in their child's primary care office, including: phone advice during and outside office hours, same-day sick visits, evening (after 5 PM) and weekend office hours, and electronic communication. National prevalence of parents' reports of each service was described using weighted survey data. Multivariate negative binomial regression was used to assess the associations between parents' report of emergency department (ED) utilization in the prior 12 months and the availability of specific enhanced access services, controlling for family sociodemographics. Analyses were performed for full study sample, as well as sub-groups with higher rates of ED use (children with special health care needs [C-ShCN], racial/ethnic minorities, and children with public insurance).

**Population Studied:** National sample of parents with children ages birth-17 years.

**Principal Findings:** 820 parents participated in the survey (response rate 41%). Most parents knew about clinic services available during weekday daytime hours, but many did not know about services outside regular office hours (don't know: weekend hours 22%, after hours phone advice 27%, evening hours 50%). The majority of parents knew about and reported usually or always having access to same-day sick visits (79%) and advice by telephone both during (80%) and outside of (54%) office hours. Less than half of parents reported access to appointments at their child's primary care office.
on weekends (47%) or any evening (23%). Few parents reported email communication or a patient portal (13%). CSHCN reported equal or more availability of enhanced access services. Racial/ethnic minorities were less likely to report access to same-day sick visits (white: 83%, black: 80%, Hispanic: 66%; p<0.05) and phone advice during office hours (white: 83%, black: 71%, Hispanic, 75%; p<0.05). Publicly-insured and uninsured children were less likely to report access to same-day sick visits (private: 84%, public: 76%, uninsured: 61%, p<0.05) but were more likely to report access to phone advice outside office hours (private: 15%, public: 25%, uninsured 21%, p<0.05).

In multivariate analysis of the whole population, the only enhanced access service significantly associated with ED use was the availability of evening hours on 5 or more nights a week (adjusted incidence rate ratio [aIRR]: 0.51 [95% CI 0.28-0.92]). In sub-group analyses, evening hours on 5 or more nights a week were also associated with lower ED use for Hispanic children (aIRR: 0.17 [0.04-0.77]) and publicly-insured children (aIRR: 0.43 [0.19-0.97]).

Conclusions: Parents are frequently unaware of enhanced access services in their child’s primary care office. Evening office hours may be effective at reducing emergency department use if available throughout the week. Future research should investigate correlations between parents’ and practices’ reports of enhanced access services and associations with ED use using objective measures, such as claims.

Implications for Policy, Delivery, or Practice: Primary care practices should communicate existing enhanced access services to families and consider expanded hours if targeting unnecessary ED use.

COMPLEX CHRONIC CONDITIONS

Exploring the Relationship between Perceived Illness Burden and Advance Care Planning among Older Adults with Chronic Illnesses

Susan Bodnar Deren, Virginia Commonwealth University

Presenter: Susan Bodnar Deren, Ph.D., Assistant Professor, Sociology, L. Douglas Wilder School of Govt and Public Affairs, Virginia Commonwealth University, smbodnar@vcu.edu

Research Objective: The objective of this study is to examine the extent to which patients’ perceived illness burden (PIB) is associated with advance care planning (ACP) behaviors (end-of-life discussions, living will (LW), and durable power of attorney for health care (DPAHC) and combined directives (LW and DPAHC)). PIB is a measure of patient appraisals that captures the complex relationship between functional limitations and perceived burden among individuals with comorbid chronic illnesses.

Study Design: Data were obtained from the New Jersey End-of-Life (NJEOL) study (2006-2008), an ethnically diverse sample of 305 non-institutionalized older adults with a number of complex chronic conditions, including cancer, Type II diabetes, and/or congestive heart failure. Patients were recruited from two large university hospitals and one comprehensive cancer center in NJ. The interview process consisted of a 1.5 hour face-to-face, structured interview and included questions regarding sociodemographics, health status and behaviors, EOL planning, and attitudes toward treatments, religion/spirituality, and social supports. The primary outcome for this study was the presence of ACP behaviors (EOL discussion, LW, DPAHC or combination). A composite variable that measures participants’ perceived illness burden is the key independent variable and was constructed based on participants’ responses to two questions assessing their current level of physical functioning (SF-12) and perceptions about being a burden to self and others (Illness Perception Questionnaire-R). Stepwise multinomial logistic regression models were estimated to examine how PIB affected the likelihood of ACP.

Population Studied: 305 non-institutionalized older adults in New Jersey. Eligible participants were aged 55 and older, either English- or
Spanish-speaking, had a working telephone, had no cognitive limitations, and identified by their doctors as having one or more of the following health conditions: cancer, Type II diabetes, or congestive heart failure.

**Principal Findings:** The respondents had a mean age of 69; 64 percent were women; and were racially diverse (56 percent white, 25 percent African-American, 19 percent Latino). Forty-six percent had a LW, 41 percent DPAHC, and 69 percent had EOL discussions. Twenty-eight percent had both a high level of disability and a high level of perceived burden, 18 percent high-disability/low-burden, 11 percent low-disability/high-burden, and 41 percent low-disability/low-burden. Multinomial logistic regression, controlling for health/sociodemographic variables revealed individuals with high PIB compared to those with low PIB were more likely to have EOL discussions (OR=2.95, CI=1.25-6.94); have a LW (OR=2.24, CI=1.03-4.87); have a DPAHC (OR=4.39, CI=1.84-9.46); and a combined directive (OR=4.73, CI=1.95-9.48). Actual illness categories and number of comorbidities did not significantly affect the likelihood of engaging in ACP.

**Conclusions:** These findings suggest that PIB is an important factor in ACP; eliciting patient perceptions about the consequences of their illness may facilitate increased levels and more meaningful ACP.

**Implications for Policy, Delivery, or Practice:** When discussing advance care planning with patients, clinicians should discuss the complex relationship between functional limitations and perceived burden among individuals with comorbid chronic illnesses. Discussions about PIB with patients may be the gateway for clinicians to engaged in ACP discussions and may increase the levels of and validity of advance care planning.

**Benefits of a Patient-Centered Medical Home for Patients with Chronic Conditions:**

**Improving the Quality of Care While Reducing Costs**

Linda Pikulin, MA; Amanda Borsky, CNA; Eric Christensen, PhD, CNA; CDR Jamie Lindly, MSC, U.S. Navy

**Presenter:** Amanda Borsky, MPP, Research Analyst, Health Research and Policy, CNA, borskya@cna.org

**Research Objective:** To understand the effect of a patient-centered medical home (PCMH) on healthcare utilization and costs for patients with chronic conditions.

**Study Design:** A retrospective analysis of a patient-level utilization database to determine the impact of the PCMH on various utilization and cost metrics using a pre-post design. Utilization measures included changes in primary care and specialty care encounters, hospitalizations, and emergency room (ER) visits, as well as provider continuity. Cost reductions were measured by per member per month (PMPM), which includes all inpatient and outpatient services, as well as pharmacy and ancillary costs.

**Population Studied:** The study included four family medicine and pediatric PCMHs that are part of the Military Health System (MHS) at U.S. Navy military treatment facilities. Patients were enrollees of each PCMH which included active duty and their dependents along with retirees and their dependents. We identified patients with chronic conditions using the Agency for Healthcare Research and Quality Clinical Classification Software categories.

Approximately 40 to 50 percent of enrolled active duty patients had one or more chronic conditions. Chronic conditions that were most prevalent among the active duty population included chronic pain, asthma, and hyperlipidemia.

**Principal Findings:** For all patients across sites, provider continuity improved with PCMH implementation (increased by 6.5% to 29.2%). Utilization of inpatient and ER services were usually less after PCMH implementation. There was little change across sites for primary care utilization. Patients with multiple chronic conditions had significantly higher PMPM costs than those without chronic conditions. For example, based on estimates for a 50-year-old male retiree, PMPM costs for those with multiple chronic conditions were between $700 and $1,400 compared to less than $200 for those without a chronic condition. The results show substantial reductions in PMPM costs and variation in PMPM costs for patients with chronic conditions (as well as for patients without chronic conditions). In fact, PMPM reductions increased with the number of chronic conditions (i.e., greater reductions in costs for the more chronically ill). PMPM costs decreased by a range of 9.4 to 22.4 percent for patients with
hypertension and decreased by a range of 2.0 to 20.4 percent for patients with diabetes.

**Conclusions:** After PCMH implementation, utilization of inpatient and ER services decreased and provider continuity improved. These findings align with the goals of PCMH to improve the continuity and quality of care. In addition, PCMH implementation also resulted in cost reductions and reduction in variation of costs. In percentage terms, PMPM changes were very similar for chronic and non-chronic patients. However, because those with chronic conditions cost 2 to 3 times more than those without chronic conditions, the PCMH model has a greater dollar cost reduction for those with chronic conditions.

**Implications for Policy, Delivery, or Practice:** These findings suggest that PCMH can not only improve the care for patients with chronic conditions, but it can also reduce the overall costs and variation of costs.

**Findings from the New York State YMCA Diabetes Prevention Program: Outcomes in a Community-based Setting**

Anne Bozack, New York Academy of Medicine; Kim Kelly, BA, New York State Department of Health; Kelly Hunt, MPP, New York State Health Foundation; Jacqueline Martinez-Garcel, MPH, New York State Health Foundation; Linda Weiss, PhD, New York Academy of Medicine, Center for Evaluation and Applied Research

**Presenter:** Anne Bozack, M.P.H., B.A., Project Director, Center for Evaluation and Applied Research, New York Academy of Medicine, abozack@nyam.org

**Research Objective:** Approximately one-third of American adults have prediabetes and are at an elevated risk of developing Type 2 diabetes. However, the Diabetes Prevention Program demonstrated that individuals who achieve modest weight reduction and participate in regular physical activity may reduce their risk between 58 and 71 percent. The New York State YMCA Diabetes Prevention Program, Y-DPP, implemented a group-based lifestyle change program through YMCA branches across New York State. This 16-week program was led by trained coaches and focused on strategies for nutrition, physical activity, and behavior change. Participants were primarily identified and referred through local health care providers. The purpose of this study was to better understand Y-DPP implementation processes and to determine the effectiveness as replicated in a community-based setting. The primary outcome was participant weight loss associated with a reduction in diabetes risk. Secondary outcomes included changes in health-related quality of life, knowledge, and behavior.

**Study Design:** A mixed methods pre-post evaluation of the Y-DPP was conducted between 2010 and 2012. Participants completed surveys at baseline, at the end of the program, and six months after program completion. Data were also gathered from weekly attendance and weight trackers. Focus groups were conducted at selected sites with current and former participants.

**Population Studied:** The study included 26 Y-DPP sections, across 14 sites. Participants, N=254, were predominantly female, 70 percent, white, 79 percent, or black, 16 percent, and had a mean age of 60.

**Principal Findings:** On an intent-to-treat basis, participants lost a mean of 11 pounds by the end of the program, p less than .05. Half of the participants achieved the goal of losing 5 percent or more of their body weight. Most participants maintained weight loss or continued to lose weight after program completion; 60 percent achieved at least 5 percent weight loss six months after the program. Self-reported general health status improved and was sustained at the six-month follow-up. A higher proportion of participants reported that their health was very good or excellent at the end of the 16 weeks. Six months after the program, more than 70 percent of participants reported that their general health was much better or somewhat better than before the program. Outcomes were consistent with qualitative findings. Participants reported improvements in physical and mental wellbeing, for example - The difference was like night and day, as far as my energy level and my mood and everything else. Participants also reported changes in health-related knowledge and behavior - I've become more aware of food portions…My wife started calling me a born again nutritionist.

**Conclusions:** The successful implementation and outcomes of this lifestyle change program by community-based YMCA branches across geographically diverse regions of New York State demonstrates the potential of the model to be replicated.
Implications for Policy, Delivery, or Practice: As private insurers and policymakers consider reimbursements for disease-prevention programs as a cost-effective alternative to clinical treatment, these findings are especially promising. Community-based settings offer existing and emerging opportunities for building community capacity to scale the National DPP and increase accessibility to populations at the highest risk for developing diabetes.

Survey of Pain Management Practices at US Hemophilia Treatment Centers: Interim Results
Tyler Buckner, University of North Carolina; Brenda Nielsen, RN, MSN, University of North Carolina - Chapel Hill; Darren DeWalt, MD, MPH, University of North Carolina - Chapel Hill; Nigel S. Key, MB, ChB, University of North Carolina - Chapel Hill; Bryce B. Reeve, PhD, University of North Carolina - Chapel Hill; Paul R. Cheminski, MD, MPH, University of North Carolina - Chapel Hill

Presenter: Tyler Buckner, M.D., Post Doctoral Fellow, Sheps Center for Health Services Research, University of North Carolina, tbuckner@unch.unc.edu

Research Objective: Hemophilia is an inherited bleeding disorder characterized by frequent joint and soft tissue hemorrhages. Repeated bleeding into joints leads to chronic arthropathy and severe, often debilitating chronic pain. In the United States, approximately 70% of persons with hemophilia receive medical care in a federally-funded comprehensive hemophilia treatment center (HTC), and two-thirds of these patients receive at least some pain management services from the HTC. Scrutiny of pain management practices has increased in response to rising numbers of deaths due to opioids in the US, but little is known about what practices are employed in US HTCs. This survey of HTCs aims to assess current approaches to pain management for patients with hemophilia, highlight strengths of the systems currently in place at HTCs, and identify potential opportunities for improvement.

Study Design: All HTCs in the United States are eligible to participate. Nurse coordinators at each HTC are contacted by telephone and asked to participate in the 58-question survey. The survey assesses HTC demographics, clinic personnel, pain assessment and management practices, documentation, and policies related to opioid medication use and follow-up procedures.

Population Studied: Federally-funded HTCs in the US, most of which are affiliated with academic medical centers. Respondents in this interim analysis are predominantly located in the southeastern US. 17 of 144 US HTCs have completed the survey as of 12/1/2012: 5 pediatric, 3 adult, and 9 combined pediatric and adult centers.

Principal Findings: Assessment: Although nearly all centers consistently ask patients to rate their pain, very few (2 of 17) HTCs systematically assess HRQoL, functional status, or other patient-reported outcomes related to pain’s impact on patients’ well-being. Only one center regularly screens for depression.

Management: Although most HTCs use opioid medications to treat chronic pain for some patients, none have defined treatment algorithms specific for pain management.

Follow-up: Follow-up and monitoring requirements are not standardized across HTCs.

Conclusions: Pain assessment and management practices vary widely among the HTCs surveyed. This interim analysis suggests that a comprehensive, systematic approach to pain management is not present in most HTCs.

Implications for Policy, Delivery, or Practice: For many individuals with hemophilia, the HTC functions as a medical home, providing management of a chronic disease and its myriad complications and coordinating care among multiple subspecialties for each patient. Pain management practices in HTCs need to be standardized to improve the quality of care provided and to enhance patient safety. Methods for designing a comprehensive pain management program and for measuring the impact of these changes need to be developed. To optimize the effectiveness of efforts to improve these clinical practices within HTCs, multiple stakeholders should be involved throughout the program’s design and implementation. Improving these systems for delivering care through the HTC network would not only impact thousands of persons with hemophilia, but it would also serve as a model for improving pain management practices in other groups of patients with chronic pain syndromes.

**One-Year Survival After Cardiac or Vascular Surgery by Pre-Existing Severe Mental Illness Status**

Laurel Copeland, Scott & White Healthcare; Central Texas Veterans Health Care System; John E Zeber, Central Texas Veterans Health Care System; Scott & White Healthcare; Eric M Mortensen, North Texas Veterans Health Care System; UT Southwestern; Mary Jo V Pugh, South Texas Veterans Health Care System; UT Health Science Center San Antonio; Edward Y Sako, South Texas Veterans Health Care System; UT Health Science Center San Antonio; Chen-Pin Wang, South Texas Veterans Health Care System; UT Health Science Center San Antonio; Valerie A Lawrence, South Texas Veterans Health Care System; UT Health Science Center San Antonio

**Presenter:** Laurel Copeland, Ph.D., Associate Director, Center for Applied Health Research, Scott & White Healthcare; Central Texas Veterans Health Care System, laurelacopeland@gmail.com

**Research Objective:** Severe mental illnesses [SMI] - schizophrenia, bipolar disorder, depression, and post-traumatic stress disorder [PTSD], are persistent disorders that affect every aspect of life including physical health. Health deficits may arise via risky lifestyle behaviors such as smoking and drinking, and impaired self-management. Individuals often develop cardiovascular disease; therefore, they may undergo cardiac or vascular surgery. This study examined whether patients with pre-operative SMI had heightened risk of death after cardiac or vascular operations.

**Study Design:** The retrospective secondary data analysis used administrative extracts from the Veterans Health Administration, relying on diagnosis codes, prescription fills, and utilization recorded in the prior year. Non-VA use was not captured. A covariate-adjusted Cox proportional-hazards model assessed correlates of one-year survival including SMI. Following preliminary test for interaction between SMI and surgery type, models assessed correlates of survival among patients having cardiac operations and among those with vascular operations only.

**Population Studied:** Patients having inpatient surgery in the VA October 2005-September 2009 were included. Exclusion criteria were index stay exceeded 29 days, illogical death data, non-veteran per VA priority status, or indeterminate inpatient facility.

**Principal Findings:** Among 55,864 patients, 35,784 had vascular operations only, 14,248 had CAVG only, 2,593 other cardiac operations primarily valve repairs, 2,225 multiple cardiac operations, and 1,014 had both cardiac and vascular operations; 1 in 5 died within one year. Rates of death varied, from 1 in 10 for CAVG to 1 in 4 for vascular operations. One in nine had SMI, mostly PTSD [6 percent]. Following cardiac operations, instantaneous risk of death was associated with married status (better survival), age (older: worse survival), and more drug effects were noted: statins, antihypertensives or hypoglycemics (better); corticosteroids or antipsychotics (worse). Bipolar disorder was associated with increased risk of death following cardiac operations [HR=1.7] but decreased risk following vascular operations [HR=0.7]. Although patients with schizophrenia had the highest rate of death at 24 percent, this diagnosis was not significantly associated with mortality within type of surgery.

**Conclusions:** High unadjusted rates of postoperative death attach to patients with preoperative psychotic disorders but SMI is a limited risk factor in covaried models of survival. The effect of bipolar disorder requires further research into potential mechanisms. The one-year death rate for patients with schizophrenia may denote relatively late referral to surgical intervention. Focused efforts to address comorbidities could improve outcomes for vulnerable patients.

**Implications for Policy, Delivery, or Practice:** Families of patients with schizophrenia should be counseled regarding the long-term survival deficit facing their loved ones. Care of patients with SMI may require collaborative planning among primary care, specialty care, and mental health providers.

**Funding Source(s):** VA

Availability of Oral Substitutes for Traditional Parenteral Cancer-Related Treatments: Impact on Therapy Initiation, Duration, and Dose Adequacy

Amy Davidoff, Agency for Healthcare Research and Quality; Franklin Hendrick, University of Maryland School of Pharmacy; Bruce D. Stuart, University of Maryland School of Pharmacy; Amer Zeidan, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins; Vu Duong, University of Maryland Marlene and Stewart Greenebaum Cancer Center; Maria R. Baer, University of Maryland Marlene and Stewart Greenebaum Cancer Center; Steven D. Gore, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins

Presenters: Amy Davidoff, Ph.D., Senior Economist, Center for Financing, Access and Cost Trends, Agency for Healthcare Research and Quality, amy.davidoff@ahrq.hhs.gov

Research Objective: Historically, parenteral (infused or injected) drugs have been the mainstay of pharmacologic cancer treatments. In recent years, development of new oral drugs for use in cancer patients has accelerated. The comparative ease of oral drug use and different toxicity profiles may expand treated patient pools, and result in improved medication adherence. Myelodysplastic syndromes (MDS) are a group of hematologic malignancies often associated with anemia, for which patients may receive chronic red blood cell (RBC) transfusions. Iron chelation therapy (ICT) is indicated in patients with transfusion-related iron overload. Parenteral-ICT is administered subcutaneously over 8-12 hours, 5-7 days/week. An oral ICT was FDA-approved in November 2005. In this study we examine how market entry of oral-ICT affected overall ICT utilization, duration, and adherence to therapy.

Study Design: This observational study examined ICT use rates, dose adequacy and adherence. ICT use was identified from procedure or drug codes on Part B or D claims. A key independent measure was calendar time relative to oral-ICT market entry. Cox proportional hazard models examined the effect of time period on the probability of ICT initiation, adjusting for followup duration. Among ICT users, Cox proportional hazard models were used to examine the effect of oral- versus parenteral-ICT use on duration.

Population Studied: Using 100% Medicare enrollment and claims data from 2005-2008, we selected beneficiaries diagnosed with MDS. Cohort members had to be enrolled in Medicare Parts A and B, but without Medicare Advantage, from 12 months before MDS diagnosis, and Part D enrolled from January 2006 or MDS diagnosis. MDS patients had to be ICT-eligible based on a history extensive RBC transfusion.

Principal Findings: Of 3,843 ICT-eligible patients 13.8% received ICT, with 81.6% of those receiving oral, and 29.5% receiving parenteral-ICT. Relative to the latter half of 2005, the risk of ICT initiation increased beginning in 2007, with a hazard ratio of 1.793 (95%CI:1.13-2.84;p=0.012) associated with cohort entry in the latter half of 2008. Treatment duration was longer for beneficiaries using oral compared to parenteral-ICT (median 47 weeks vs. 17 weeks, p<0.01). Only 7.1% of parenteral-ICT users received an adequate dose, compared to 72.8% of oral ICT users.

Conclusions: Market entry of an oral ICT agent was associated with increased use of ICT among Medicare beneficiaries with MDS. Among ICT users, oral ICT was associated with substantially longer duration and dose adequacy.

Implications for Policy, Delivery, or Practice: A key motivation for development of oral cancer drugs is the expanded access to prescription benefits associated with Medicare Part D. As oral substitutes for parenteral drugs enter the market, the question will be whether access to appropriate therapy is improved, and whether patients are more likely to complete the recommended duration of therapy at meaningful doses. Our study suggests that oral formulations are associated with better patient compliance and adherence, which may lead to improved outcomes in the future. Increases in cost of therapy and spending shifts to Part D are likely.

Differences in Health Services Utilization and Costs between Antihypertensive Medication Users Versus Non-Users in Adults with Diabetes and Concomitant Hypertension from MEPS Pooled Years 2006-2009

Mary Lynn Davis-Ajami, University of Maryland, Baltimore; Jun Wu, PhD, Assistant Professor, South Carolina College of Pharmacy, University of South Carolina; Jeffrey C. Fink, MD, Professor, Departments of Medicine and Epidemiology and Public Health (secondary), University of Maryland School of Medicine, Baltimore
Presenters: Mary Lynn Davis-Ajami, Ph.D., M.B.A., M.S., Assistant Professor, Organizational Systems and Adult Health, School of Nursing, University of Maryland, Baltimore, davis-ajami@son.umd.edu

Research Objective: To compare population level baseline characteristics, individual level utilization and costs between antihypertensive medication users versus non-users in adults with diabetes and concomitant hypertension.

Study Design: We used a longitudinal retrospective observational research design using public use Medical Expenditure Panel Survey household component (MEPS-HC) pooled years 2006-2009 data to analyze adults > 18 years with non-gestational diabetes and coexistent essential hypertension. Two groups were created: 1) antihypertension medication users. 2) no antihypertensive pharmacotherapy. We examined emergency department (ED) and hospital utilization, and average annualized health care costs. Accounting for MEPS complex survey design, longitudinal weight was used for all analyses. Logistic regressions examined likelihood of utilization and any antihypertensive medication use and multiple linear regression models with log transformation assessed association between costs and antihypertensive medication use.

Population Studied: A cohort of adults aged > 18 years from the US civilian non-institutionalized population with non-gestational diabetes and coexistent essential hypertension.

Principal Findings: We identified 3261 adults with diabetes. Of those, 66% (n=2137) had concomitant hypertension representing 38.7 million individuals during 2006-2009. 16% (n=338) lacked prescriptions for antihypertension pharmacotherapy representing a weighted population frequency approximating 425,000. Mean age was 62.9 years and the overall sample was predominately female (52%) white (77%), from the southern US geographical region (42%), high school educated (50%), insured with private insurance (57%), from higher income levels, and in fair to poor perceived health status (48%). Significantly, the non-antihypertensive pharmacotherapy users were from white racial backgrounds (82% vs. 77% p = 0.033), fewer of black race (12% vs. 18%, p = 0.038), single (51% vs. 43%, p = 0.048), with 11% fewer covered by private insurance (47% vs. 58%), 7% more uninsured (13% vs. 6%) and 4% more covered by public insurance (40% vs. 36%, p < 0.001) than antihypertensive medication users. Significantly, the 16% (n= 338) non-antihypertensive pharmacotherapy group showed greater mean nights hospitalized (3.6 versus 1.7, p = 0.0120), greater all-cause hospitalization per 1000 patient month (41 versus 24, p = 0.0007), 64% greater likelihood for hospitalization, lower mean diabetes-related, and hypertension-related ambulatory visits, 32% lower total average annualized expenses , and 32% lower average annualized medical utilization expenses compared to antihypertensive medication users.

Conclusions: We observed significantly different baseline characteristics, greater hospitalization, and lower costs between antihypertension medication users versus non-users in adults with diabetes and coexistent hypertension.

Implications for Policy, Delivery, or Practice: The substantially greater hospitalization with lower expenses among non-antihypertensive medication users with diabetes and concomitant hypertension warrant further study. These findings may reflect a possible overall disengagement from regular, customary care which may serve to drive down short-term costs, whereas our findings for greater hospitalization may affect costs over the long-term. Given tight BP control guidelines and known poor health outcomes from elevated BP in individuals with diabetes, those not using any antihypertensive pharmacotherapy in the presence of known essential hypertension may represent a vulnerable population deserving additional research and health care provider attention.

Association of Patient Experience with Care Coordination, Outcomes, and Multiple Chronic Conditions

Eva DuGoff, Johns Hopkins University School of Public Health

Presenter: Eva DuGoff, M.P.P., Graduate Student, Department of Health Policy and Management, Johns Hopkins University School of Public Health, edugoff@gmail.com

Research Objective: This study explores the relationship between patient experiences of care coordination and patient-reported emergency room (ER) use and hospital use in older adults with multiple chronic conditions.
Study Design: Survey data were collected using a two-stage mail survey from July 2011 to September 2011. The survey was a 45-item questionnaire including questions on patient experiences with care coordination: 1. In the last 6 months, when your doctor ordered a blood test, x-ray or other test for you, how often did someone from your doctor’s office follow up to give you those results? 2. Does your doctor give you a written plan or instructions to help you manage your own care at home? 3. In the past 6 months, has any doctor given you instructions for one of your conditions that conflicted with what you have been told to do for another condition? 4. In the last 6 months, how often did your doctor seem informed and up-to-date about the care you received from specialist physicians? 5. In general, do you think the doctors you see communicate with each other about your care? Survey data were linked to administrative claims from July 2010 to September 2011 and demographic data from a Medicare Advantage Special Needs Plan. Population Studied: 765 survey respondents who were members of a Medicare Advantage Special Needs Plan enrolled in Alabama, Georgia, Mississippi, South Carolina, and Texas. Principal Findings: We find that only some patient experience measures are associated with self-reported ER use and hospital use. Subjects reporting not always receiving a written plan had greater odds of reporting ER use and hospital use. The odds of ER use increased with increasing numbers of co-morbidities among subjects reporting not always receiving written instructions. However, we observed the inverse relationship among subjects who reported not always receiving a written plan and hospitalization. Reported receipt of conflicting advice was associated with greater odds of ER use, but was not associated with hospital use. Among subjects who reported receiving some conflicting advice, the odds of ER use decreased with increasing co-morbidities. Conclusions: Previous studies have suggested that more concrete questions get more reliable responses that are more closely associated with care outcomes. While this is generally confirmed with this analysis, we find that patient reported receipt of written instructions or care plan is most highly correlated with ER and hospital use. The relationship between patient experiences items and outcomes varies by number of chronic conditions.

Implications for Policy, Delivery, or Practice: In using patient experience measures to assess providers, it is important to consider which adverse events or outcomes these measures predict. Policymakers should consider including additional patient experience measures in the patient experience surveys that are predictive of use and poor outcomes.

Comparing the Effectiveness of an Innovative Surgical Approach for the Definitive Treatment of Patients with Ulcerative Colitis

Krista Evans, Sheps Center for Health Services Research; Jennifer Samples MD, University of North Carolina Healthcare--Department of General Surgery; Timothy Sadiq MD, University of North Carolina Healthcare--Division of Gastrointestinal Surgery; Mark Koruda MD, University of North Carolina Healthcare--Division of Gastrointestinal Surgery

Presenter: Krista Evans, M.D., M.S., Postdoctoral Research Fellow, General Surgery, Sheps Center for Health Services Research, kevans@unch.unc.edu

Research Objective: Ulcerative Colitis (UC) is an inflammatory disease of the colon, and in severe or persistent disease, can be treated surgically with Proctocolectomy with Ileal Pouch Anal Anastomosis (IPAA). However, this procedure is prone to anastomotic complications. In patients who are at moderate or high risk for a postoperative complication (nutritionally deplete, on high dose/long term corticosteroid therapy, or fulminantly or acutely ill from UC) a diverting loop ileostomy is widely utilized at the time of IPAA to minimize risk of postoperative leak, abscess or pelvic sepsis. The objective of our study is to determine if anastomotic leak risk associated with IPAA is a consequence of the operation itself or the condition of the patient when the operation is performed. Our practice is to perform an innovative variant 2-stage procedure for higher risk patients (abdominal colectomy followed by completion proctectomy/IPAA once the patient has improved clinically and nutritionally). Pouch creation following this management should be of similar risk to those who are less ill and undergo a single-stage procedure.
Study Design: This is a retrospective review of the electronic medical record within the University of North Carolina Hospitals system of all patients with UC who underwent IPAA surgery from 2003-2009. Patients were grouped according to procedure: variant 2-stage compared to single and classic 2-stage. To evaluate the difference in preoperative population characteristics and risks for postoperative complications, we performed bivariate analyses using chi-square and t-test. At the time of the meeting, we will have collected and analyzed data on body mass index, number of inpatient hospital days from time of first surgery, and number of operations more than anticipated for the staged procedure. Our primary endpoint: demonstrable pouch leak, and secondary endpoints: intraabdominal abscess and stoma complications were compared using stepwise logistic regression and controlling for significant preoperative factors associated with a postoperative complication.

Population Studied: 109 (33%) patients underwent variant 2-stage and 219 (67%) patients underwent single and classic 2-stage surgeries combined.

Principal Findings: Statistically different risk factors for postoperative complication between the two groups (variant 2-stage versus single- and classic 2-stage) include dysplasia/cancer diagnosis (5.5% 21.5%); urgent or emergent indication for surgery (58.7%, 0.5%); and overall (83%,53%), high dose (53%, 8%), and long term (60%, 41%) steroid use at first procedure. Gender, age, length of follow-up, tobacco use, diabetes mellitus, 5-aminosalicylic acid, immunologic, or biologic use at first procedure did not differ significantly between the groups. The odds of demonstrable pouch leak were significantly decreased (0.39; 0.19-0.82) in the variant-2 stage compared to the single and 2-stage procedure. The odds of intraabdominal abscess (1.07; 0.46-2.53) and stoma complications (0.71; 0.38-1.34) were not significantly different.

Conclusions: While the variant 2-stage patients had more pre-operative risk factors for postoperative complications, this group had equivalent or better postoperative outcomes than the single or classic 2-stage patients. These data suggest that anastomotic complications after IPAA for UC are more the consequence of the conditions under which IPAA is performed, rather than the procedure itself.

Implications for Policy, Delivery, or Practice: Utilization of a variant 2-stage IPAA permits chronically and acutely ill UC patients to be managed safely. This could decrease number of operative procedures and hospital admissions and thereby improve quality of life for these chronically ill patients.

Impact of Behavioral Health Disorders on Cost, Quality and Outcomes of Care for Maine Medicaid Members with Diabetes and Other Chronic Medical Conditions

Elsie Freeman, Maine Department of Health and Human Services; Jay Yoe PhD, Maine DHHS Office of Quality Improvement; Catherine McGuire, USM Muskie School; Deborah Thayer, USM Muskie School; Tina Gressani, USM Muskie School; William Thomas, PhD, USM Muskie School

Presenter: Elsie Freeman, Medical Director, Office of Quality Improvement, Maine Department of Health and Human Services, Elsie.Freeman@maine.gov

Research Objective: This longitudinal study assesses the impact of behavioral health disorders (BH) on cost, utilization, quality and outcomes for long-term Mefdicaid(MaineCare) enrollees and informs development of analytic infrastructure for evaluation of Health Homes and other health system re-design efforts.

Study Design: The cohort consists of five behavioral health (BH) populations: no BH; mental illness, substance abuse; co-occurring mental illness/substance abuse; and intellectual/developmental disability. Analyses of administrative and vital statistics data describe factors affecting cost, utilization, quality and outcomes for persons in each of the BH groups, stratified by the number of chronic medical co-morbidities.

Population Studied: The cohort consists of 63,141 adult MaineCare members followed over five years. Medicaid members differ from other insured populations given their high degree of social stressors: poverty, unemployment, low education, unstable food and housing.

Principal Findings: 49% of the cohort has at a BH disorder. MaineCare members have high rates of medical co-morbidities; those with BH disorders have significantly higher rates of each chronic medical condition and greater numbers of multiple co-morbidities; 40-50% of those with...
BH disorders have 3 or more medical co-morbidities compared to 21% of those with no BH diagnosis. Among BH groups medical costs exceed BH costs. Medical costs rise in tandem with increasing numbers of medical co-morbidities, but having any BH disorder accounts for as much increase is having 3 medical conditions. At any level of medical co-morbidity, medical costs increase by 25-250% depending on the BH sub-group. Utilization of medical services (emergency Room, hospital, 30 day readmission, avoidable hospitalization) is significantly higher among those with BH disorders. BH costs are likewise influenced by the number of medical conditions in certain BH-disordered populations. Those with BH disorders have higher prevalence of diabetes and diabetes complications, lower quality care and over time, worsening diabetes, new incidence of diabetes and death compared to those with no BH disorder. Improved BH status appears to protect against worsening diabetes over time, while a declining BH status increases risk of death among those with diabetes by 73%.

Conclusions: Long term Medicaid members with high degrees of social stressors have high rates of BH disorders and multiple chronic medical conditions. Specific findings vary by BH group, but generally members with BH disorders have higher service utilization and costs, greater burden of diabetes and other chronic diseases, and greater morbidity/ mortality than members with no BH disorders.

Implications for Policy, Delivery, or Practice: As health systems move to greater accountability for whole populations and new reimbursement systems, it is critical that system re-design includes strategies targeting the needs of the most complex patients who have multiple medical and behavioral health disorders as well as socio-economic stressors. Improving cost effectiveness, quality of care and outcomes for these populations depends on developing structures supporting integration, across physical and behavioral health, in surveillance, research methodology and provision of care. Medicaid administrative and vital statistics data are useful resources for longitudinal comparative effectiveness research on high-need populations. Standardized systems for analysis of Medicaid data has promise for comparing effectiveness of different policies being implemented under health care reform across multiple states.

Readmission Rates and Total Medical Cost Differences between Medicare Beneficiaries with Atrial Fibrillation or Other Conditions Vary by Initial Admission Type

Sloane Frost, Mathematica Policy Research, Incorporated; Mai Hubbard, PhD, Mathematica Policy Research, Inc.; Kimberly Siu, MD, MPH, Boehringer Ingelheim Pharmaceuticals, Inc.; Nicole Quon, PhD, Optimer Pharmaceuticals, Inc. (formerly with Boehringer Ingelheim Pharmaceuticals, Inc.); Dominick Esposito, PhD, Mathematica Policy Research, Inc.

Presenter: Sloane Frost, MPP, Research Analyst, Mathematica Policy Research, Incorporated, sfrost@mathematica-mpr.com

Research Objective: Improving post-hospitalization quality of care via successful care transitions depends on many factors, including the reason for hospitalization. This study examined the relationship between 30-day post-discharge readmission rates and total medical costs in the 12 months after discharge, by reasons for the initial admission, for Medicare beneficiaries with atrial fibrillation (AF) and those without AF but with other chronic conditions (CAD, COPD, heart failure [HF], and diabetes).

Study Design: We calculated risk-adjusted beneficiary-level readmission rates and post-discharge 12-month medical costs, controlling for demographic characteristics, comorbidities, and previous health care use. We calculated these outcomes for six types of high-cost index discharge diagnoses: acute myocardial infarction (AMI), HF, stroke, CABG, and percutaneous coronary intervention (PCI).

Population Studied: Medicare Fee for Service (FFS) claims and enrollment data (2006-2009) from the Chronic Condition Warehouse (CCW) were used to analyze both groups. Beneficiaries were randomly selected from the Medicare FFS population: those with AF were drawn from a 10% random sample of AF patients, and the comparison group was from a 2% random sample of all Medicare beneficiaries. The study population included 99,272 patients (43,367 with AF) ranging from 56,824 admitted for bleeding to 5,558 for CABG.

Principal Findings: For all initial admission types, 30-day readmission rates were higher for the AF group. Differences between the AF and non-AF groups were largest for those with an index discharge diagnosis for AMI (33% higher), CABG (20% higher), or PCI (30% higher)
admission. Total medical costs in the 12 months after discharge were also always higher for those with AF. The largest difference (18%) was after admission for AMI ($28,890 with AF vs. $24,500 without AF), which was significant at the p<0.01 level. All other differences in total medical costs were less than 10% between the groups, and average expenditures were 7.9% higher for beneficiaries with AF across all index admissions measured.

**Conclusions:** Medicare beneficiaries with AF had higher 30-day readmission rates than their peers with other common chronic illnesses regardless of their initial admission type (4.3% higher for initial admission of heart failure, 19.8% for CABG, 23.1% for stroke, 33.2% for AMI, and 29.6% for PCI). Differences between the groups varied by the index discharge diagnosis. Similarly, expenditures were higher for beneficiaries with AF compared to other Medicare FFS beneficiaries with common chronic conditions, but these differences varied by initial admission type.

**Implications for Policy, Delivery, or Practice:** These findings underscore the need for CMS to examine the service utilization and health outcomes for beneficiaries with AF, who present challenges in regards to cost containment and readmission outcomes as much as, if not slightly more than, beneficiaries with other common chronic conditions. Particularly as medical providers work to reduce readmissions and improve health outcomes, AF beneficiaries represent a vulnerable and large population whose quality of life and financial savings can be improved with a better understanding of the relationship of initial discharge diagnosis type to subsequent readmissions.

**Primary Care-Integrated Complex Care Management Programs: Lessons from Early Adopters**

Clemens Hong, Harvard Medical School/Massachusetts General Hospital; Allison L Siegel, Massachusetts General Hospital; Timothy G Ferris, Massachusetts General Hospital

**Presenter:** Clemens Hong, Instructor Of Medicine, Medicine, Harvard Medical School/Massachusetts General Hospital, cshong@partners.org

**Research Objective:** To assess key operational attributes of leading primary care-integrated complex care management programs (PC-CCMPs).

**Study Design:** Based on literature review and recommendations from an expert steering committee, we identified 20 operating, PC-CCMPs that met inclusion criteria: a whole-person focus and existing data indicating positive outcomes. We performed three 1-hour key informant interviews (an executive leader, a program manager, and a front-line care manager (CM)) at each of the 18 PC-CCMPs that agreed to participate. We assessed 8 domains: context, patient selection, patient engagement, primary care engagement, CM team structure, key activities and resources, information technology (IT), and CM training. Two investigators independently reviewed detailed notes from each audiotaped interview and then collectively identified key recurring themes.

**Population Studied:** Three key informants from each of 18 PC-CCMPs across the US

**Principal Findings:** Located in more than 14 states, the programs served urban (15) and rural (6) populations insured by commercial payers (8), Medicare (10), and Medicaid (8). Payers (7), delivery systems (8), and regional CM entities (4) managed PC-CCMP operations. Three programs served both urban and rural settings, 8 were multi-payer initiatives, and payer/delivery system partners jointly operated 2 programs. Only 5 programs were components of a broader primary care transformation initiative. Existing evaluation data from these PC-CCMPs revealed increased quality, provider and patient experience, and decreased mortality, acute care utilization, and costs.

PC-CCMPs selected patients based on risk prediction models, event-triggers (e.g. hospitalization), referral, or hybrids of these approaches; identifying mutable patients was a challenge with no consensus. Co-location of the CM, early/regular face-to-face interaction, cultural concordance (finding the right CM fit for diverse patients and practices), achieving early successes, and focus on longitudinal relationships were keys to both patient and provider engagement. CM team structure varied considerably in their make-up and level of integration depending on context and target population; however, the majority leveraged a multidisciplinary team-based approach to meet complex patient needs and improve efficiency. PC-CCMPs used different approaches to
engage important community-care partners such as hospitals/EDs, skilled nursing facilities, and community-based home health, behavioral health, and social service agencies. CM caseloads ranged from 25-200 patients and depended on patient complexity, intensity of intervention, CM training, and support from technology and a multidisciplinary team. Patient touches were frequent and often face-to-face, in the clinic or community. The central task of the CM was to build trusting relationships with the patient, physician, and other community-care partners. Other tasks included: comprehensive assessment and creation of a care plan to address needs/barriers, self-management support, care coordination, and patient advocacy. Care Management IT infrastructure was generally limited, and programs universally identified motivational interviewing as the most important component of CM training.

Conclusions: Health care costs are concentrated in a small group of complex individuals. Payers and healthcare delivery systems are increasingly looking to use CMs to improve care and reduce costs for their complex patients. Interviews of key informants in 18 successful PC-CCMPs reveal numerous shared operational attributes.

Implications for Policy, Delivery, or Practice: As health systems adopt PC-CCM strategies, they should apply lessons from these successful PC-CCMPs to optimize opportunities to improve care and reduce costs.

Funding Source(s): CWF

Primary Care-Integrated Complex Care Management Programs for Medicaid and Dual-Eligible Patients: Lessons from Early Adopters
Clemens Hong, Harvard Medical School/Massachusetts General Hospital; Allison L Siegel, Massachusetts General Hospital; Timothy G Ferris, Massachusetts General Hospital

Presenter: Clemens Hong, Instructor Of Medicine, Medicine, Harvard Medical School/Massachusetts General Hospital, cshong@partners.org

Research Objective: To assess key operational attributes and best practices of leading primary care-integrated, complex care management programs (PC-CCMPs) serving Medicaid and dual-eligible (M&DE) patients.

Study Design: Based on literature review and recommendations from an expert steering committee, we identified 20 operating, PC-CCMPs that met inclusion criteria: whole-person focus and existing data indicating positive outcomes. We performed 1-hour, semi-structured interviews with 3 key informants (executive leader, program manager, and care manager (CM)) from each of the 18 PC-CCMPs agreeing to participate. In a subset of 10 programs that served M&DE patients, we identified M&DE-specific approaches in the following domains: patient selection and engagement, primary care engagement, CM team structure, key activities and resources. Two investigators independently reviewed detailed notes from each audiotaped interview and then collectively identified recurring themes and best practices.

Population Studied: Three key informants from each of 10 PC-CCMPs serving M&DE patients across the US.

Principal Findings: Located in urban (8) and rural (4) settings in 10 states, PC-CCMP operations were managed by payers (4), delivery systems (5), and regional CM entities (3). Two programs served both urban and rural settings, 3 were multi-payer initiatives, and payer/delivery system partners jointly operated 2 programs. Existing evaluation data from these PC-CCMPs revealed increased quality, provider/patient experience, and decreased acute care utilization/costs. PC-CCMPs selected patients based on quantitative (e.g. risk prediction models) or qualitative (e.g. referral) approaches, or hybrids of the two. Respondents felt that qualitative approaches were better for identifying mutable patients. Patient engagement was challenging due to a high level of mobility, competing priorities, poor communication access, loss of insurance coverage, and issues of trust. PC-CCMPs used many approaches to address these issues including: early/regular face-to-face interaction, use of culturally concordant CM team members, such as community health workers (CHWs), increased emphasis on harm-reduction strategies and motivational interviewing, and greater integration with behavioral health providers. Several PC-CCMPs maintained discretionary funds to address patient needs, and one program provided free cellular phones to patients to increase engagement. CM caseloads ranged from 25-150 patients, but were much lower than PC-CCMP counterparts serving Medicare and commercial
Depression as a Risk Factor for Poor Self-Care in Patients Hospitalized with Heart Failure

Mary Johantgen, University of Maryland School of Nursing; Robin P. Newhouse, University of Maryland School of Nursing; Sue Thomas, University of Maryland School of Nursing; Heesook Son, Consultant

Research Objective: Meta-analytic results have demonstrated that depression in heart failure (HF) is associated with poorer health outcomes (Rutledge et al, 2006). Yet, the mechanisms for these relationships are not clear. For patients hospitalized with HF, the objectives of this study were to: 1) describe the frequency of depressive symptoms by demographic factors; and 2) to examine the relationship between depressive symptoms and self-care confidence, self-care management, readiness for discharge, and HF knowledge.

Study Design: The descriptive study reported here was a part of a prospective cohort, multi-site study of HF patients in U.S. hospitals achieving Magnet® Recognition. The Improving Heart Failure Outcomes (IHO) study was designed to evaluate the effect of standardized nursing education on HF patient outcomes after discharge. Depressive symptoms were measured with the Beck Depression Inventory and then aggregated to four levels based on scoring guidelines. The Self-Care Heart Failure Index V6.2 (Riegel, 2012) measured self-care maintenance, management, and confidence.

Population Studied: The 492 patients studied were admitted to a single unit in one of 40 Magnet® hospitals who volunteered to participate. Patients meeting inclusion criteria (primary diagnosis of HF, speaking English, anticipated discharge to home) were recruited on admission to the hospital. Patients were excluded from analyses if they had an intervention procedure or transferred to another hospital unit, or were not discharged to home.

Principal Findings: Twelve percent of the entire sample was assessed as having moderate or severe levels of depressive symptoms. Age, measured with 3 levels, was significantly related to depressive symptoms [X2(9) = 30.344, p<.001]. Patients older than 65 years most frequently experienced mild depressive symptoms, whereas patients 51-65 years had the highest proportions of moderate/severe depressive symptoms. Depressive symptoms did not significantly vary by gender, New York Heart Association (NYHA) class, education, or ethnicity. However, self-care confidence [F (3, 561) = 6.561, p<.001] and patient readiness for discharge [F (3, 447) = 5.321, p<.001] were significantly different among the four depressive symptom groups. Patients with minimal depressive symptoms reported higher self-care confidence as compared to those with mild depressive symptoms (p<.001). Patients with minimal depressive symptoms reported higher scores of readiness for discharge (p=.003) as compared to those with higher levels of depression. Self-care management and knowledge of HF were not significantly different in patients with HF who were depressed.

Conclusions: HF patients with higher levels of depressive symptoms are less ready for discharge from acute care hospitals and have less self-confidence in their ability to manage their HF at home despite having no difference in HF knowledge, or self care management and
maintenance. Younger HF patients may be at particular risk for depression.

**Implications for Policy, Delivery, or Practice:**
Individuals who have co-morbid depression with HF may require better psychological assessment, additional discharge planning, and closer follow-up to support self-care and potentially prevent readmission. Symptoms of depression should routinely be assessed even for younger HF patients.

**Effect of Chronic Illness Complexity on Receipt of Evidence-Based Depression Care**
Neil Jordan, Northwestern University Feinberg School of Medicine; Min-Woong Sohn, Northwestern University Feinberg School of Medicine; Brian Bartle, Hines VA Hospital; Marcia Valenstein, University of Michigan; Todd Lee, University of Illinois-Chicago

**Research Objective:** The rate of guideline concordance with antidepressant treatment among veterans with new episodes of depression is low. The problem may be even more pronounced for depression patients with coexisting, multiple chronic conditions (MCC). The objective of this study is to examine, for persons with new episodes of depression, the effect of various groups of chronic diseases (clusters of MCC) on the likelihood of receipt of evidence-based depression treatment.

**Study Design:** In this study of Veteran Affairs (VA) patients, we used VA administrative data to identify our depression-MCC cohort, which consisted of VA patients who experienced a new depressive episode in 2007. Comorbid conditions for the study cohort were identified during the year prior to the first date of depression diagnosis in 2007 (index date) using ICD-9 codes from AHRQ Clinical Classification Software. We focused on chronic conditions managed with medication or psychosocial interventions (arthritis, cardiovascular & cerebrovascular conditions, diabetes, infectious disease, non-melanoma cancer, peptic ulcer/GERD, respiratory disease, substance/alcohol abuse). Patients were assigned to mutually exclusive clusters based on the grouping of these 8 conditions. Guideline concordant (GC) depression care was defined during both acute (12 weeks) and continuation (180 days) phases and includes adequate receipt of antidepressant medications. We determined the association between clusters of chronic illness and likelihood of receipt of GC depression care while adjusting for age, race, marital status and gender.

**Population Studied:** We identified a cohort of 531,932 VA patients, ages 18-64, who had a new depressive episode during 2007.

**Principal Findings:** A total of 43,189 patients met the inclusion criteria. Nearly 90% of the cohort was male with an average age of 55. Overall, 63.4% of veterans received GC depression care during the acute phase, and 37% received GC care through the continuation phase. Compared to patients with depression alone, those with cardio-/cerebrovascular disease, peptic ulcer/GERD, or arthritis had 8%-13% higher odds of receiving GC depression treatment during the acute phase (p<.01). Patients with depression and substance/alcohol abuse had 15% lower odds of receiving acute phase GC depression treatment than patients with depression alone (p<.01). Compared to patients with depression alone, those with cardio-/cerebrovascular disease or peptic ulcer/GERD had 9%-10% higher odds of receiving GC depression treatment during the continuation phase (p<.01). Patients with depression and substance/alcohol abuse had 19% lower odds of receiving acute phase GC depression treatment than patients with depression alone (p<.01). Relatively few of the most prevalent MCC clusters were significantly associated with receipt of GC depression treatment.

**Conclusions:** Over 1/3 of veterans with an acute depressive episode failed to receive short-term, evidence-based depression care, and nearly 2/3 did not receive recommended treatment out to 180 days. There was no consistent association between specific clusters of chronic conditions and guideline concordant depression care.

**Implications for Policy, Delivery, or Practice:**
The proportion of veterans with an acute depressive episode that receive optimal depression treatment is suboptimal. There continues to be need for practice- and system-level interventions to increase quality of depression treatment for persons with an acute depressive episode.

Health Insurance-Motivated Disability Enrollment: Implications for Policy and Research
Jae Kennedy, Washington State University, Spokane; Elizabeth Blodgett, Department of Health Policy and Management, University of North Carolina, Chapel Hill

Presenter: Jae Kennedy, Ph.D., Professor, Health Policy and Administration, Washington State University, Spokane, jjkennedy@wsu.edu

Research Objective: The United States currently relies on employer-based health insurance to cover working-age adults and their families. As a result, Americans who are unable to engage in full-time work because of a chronic health condition must not only seek out wage replacement, but also pursue alternative sources of health insurance. However, purchasing private insurance is rarely an option for this population, owing to high costs and structural barriers such as lifetime spending caps, waiting periods, and exclusions of preexisting conditions from coverage. Consequently, workers often apply for disability benefits in part to obtain public health insurance; a uniquely American phenomenon that we call health insurance–motivated disability enrollment (HIMDE). The Patient Protection and Affordable Care Act of 2010 has the potential to significantly reduce HIMDE by expanding health insurance coverage options for workers with disabilities.

Study Design: Review of the disability and health policy literature.

Principal Findings: The Affordable Care Act contains multiple major reforms that should reduce new health insurance–motivated applications for disability benefits and increase the percentage of enrollees who return to work. It achieves this through policy changes in the private and public insurance systems that benefit different subgroups among people with disabilities.

Conclusions: There is unlikely to be an immediate large and sustained drop in enrollment in disability programs, owing to various economic and demographic factors. The aging of the U.S. population, tight economic conditions driving disabled workers out of the job market, and raising of the retirement age will all increase pressure on disability programs even as HIMDE decreases after the ACA’s implementation.

Implications for Policy, Delivery, or Practice: As the ACA is implemented and evaluated, we urge health services and disability researchers to consider a reduction in HIMDE as an important measure of the success of health care reform for Americans with disabilities.

Multimorbidity and Long-Term Care Dependency – A Five Year Follow-Up
Daniela Koller, Dartmouth Institute for Health Policy and Clinical Practice; Gerhard Schoen, University Medical Center Hamburg-Eppendorf; Martin Scherer, University Medical Center Hamburg-Eppendorf; Hendrik van den Bussche, University Medical Center Hamburg-Eppendorf; Gerd Glaeske, Centre for Social Policy Research, University of Bremen; Ingmar Schaefer, University Medical Center Hamburg-Eppendorf; Heike Hansen, University Medical Center Hamburg-Eppendorf

Presenter: Daniela Koller, Researcher, Dartmouth Institute for Health Policy and Clinical Practice, koller.daniela@googlemail.com

Research Objective: Not only single, but multiple chronic conditions are becoming the normal situation rather than the exception in the older generation. Yet, treatment guidelines still focus on single diseases and do not include the complexity of multiple chronic diseases. Previous studies showed a correlation between multimorbidity and functional impairment, but the impact on long-term care dependency is not clear yet. The objective of this study is to follow up a cohort of older adults over 5 years to estimate the impact of multiple chronic conditions on long-term care dependency.

Study Design: This study is based on claims data of a large German statutory health insurance company. Individual information of all insured persons is available in pseudonymous form. The main outcome was the time until long-term care dependency. The follow up started on January 1st, 2005 and lasted for 5 years until December 31st, 2009. To evaluate differences between persons with multimorbidity and those without we first calculated Kaplan-Meier curves, stratified for multimorbidity. Furthermore, three distinct Cox
Multimorbidity was defined as three or more chronic conditions based on ICD-10 codes. Multimorbidity was defined as three or more chronic conditions out of this list.

**Principal Findings:** Mean follow-up was 4.5 years. Persons with multimorbidity had a higher risk of becoming care dependent (HR: 1.85, CI 1.78-1.92). After five years, 91.3% of those without multimorbidity are still not care-dependent, compared to 84.7% in the multimorbid group (p for log rank <.0001). This result remains significant after adjusting for age and sex. With every year of age the risk for care dependency increases by 16%; sex does not have a significant influence. The conditions with the highest risks long-term care dependency are Parkinson’s disease and dementia. For both diseases, the risk for care dependency is significantly higher for non-multimorbid persons (HR of 6.40 vs. 2.68 for Parkinson and HR: 5.70 vs. 2.27 for dementia, respectively).

**Conclusions:** Our results point to a higher influence of degenerative diseases on long-term care dependency, also showing that specific diseases have a stronger impact for patients that do not have multiple chronic diseases. Through the inclusion of 46 chronic conditions and the large database those results can add newer and broader knowledge to the existing evidence on multimorbidity and care dependency.

**Implications for Policy, Delivery, or Practice:** The results should form the basis for future health policy decisions on the treatment of patients with multiple chronic diseases and also show the necessity to introduce new ways of long-term care provided to this population. A health policy focus on chronic care management already in the ambulatory setting and introducing guidelines for multimorbidity is crucial to secure health services delivery for the older population.

**Multiple Chronic Comorbidities in Type 2 Diabetes: Prevalence and Consequences**

Pei-Jung Lin, Center for the Evaluation of Value and Risk in Health, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, USA; Pei-jung Lin, Tufts Medical Center; Aaron Winn, M.P.P., Center for the Evaluation of Value and Risk in Health, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, USA; Joshua T. Cohen, Ph.D., Center for the Evaluation of Value and Risk in Health, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, USA; David M. Kent, M.D., M.Sc., Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, USA; Peter J. Neumann, Sc.D., Center for the Evaluation of Value and Risk in Health, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA, USA

**Presenter:** Pei-jung Lin, Ph.D., Assistant Professor, Center for the Evaluation of Value and Risk in Health, Tufts Medical Center, plin@tuftsmedicalcenter.org

**Research Objective:** Despite the predominance and high costs of multiple chronic comorbidities (MCCs) among diabetes patients, which condition clusters are most prevalent and most influential in predicting adverse outcomes remains unclear. This study examined the most common patterns of MCCs, and assessed hospital readmissions and emergency room (ER) visits associated with specific condition clusters.

**Study Design:** Cross-sectional analysis of the 2008-2012 Humedica dataset containing data extracted from electronic health records, encounter files, and lab values supplied by U.S. providers. Of the 14 comorbidities in the 2012 American Diabetes Association guidelines, we selected the eight conditions that each affected >=10% of the patients and analyzed the most common patterns of mutually exclusive clusters in a type 2 diabetes cohort (n=162,332). We calculated the percent of total 30-day readmissions and total ER visits by MCC cluster. We used logistic regression models to explore the risk of readmissions and ER visits in MCC subgroups, controlling for age, sex, race, neighborhood income, insurance status, HbA1c, BMI, cholesterol, blood pressure, number of office visits, and number of prescription drugs.

**Population Studied:** 162,332 adults (aged >=18 years) with type 2 diabetes who had >=24 months of ambulatory and hospital data from integrated delivery networks.
Principal Findings: 89.1% of diabetes patients had >=1 comorbidity and 40.9% had >=3. The leading combination of MCCs was hypertension and hyperlipidemia only (21.1%). Overall, 62.5% of patients had this combination plus one other condition and 27.6% had the combination plus two other conditions. Other common clusters included hypertension only (10.9%), hyperlipidemia only (5.0%), and the combination of hypertension and hyperlipidemia plus coronary artery disease (CAD, 4.7%). 19.4% of subjects discharged from the hospital were readmitted within 30 days, and 23.2% had at least one ER visit during the study period. 15.3% of total readmissions and 19.3% of ER visits were for patients who had co-existing hypertension and hyperlipidemia, or who had this cluster plus CAD and/or chronic kidney disease (CKD). The likelihood of readmissions and ER visits significantly increased with the number of comorbidities. Compared with subjects without any comorbidity, individuals with CAD and/or CKD in addition to hypertension and hyperlipidemia were significantly more likely to have readmissions (ORs=1.01-2.11) and ER visits (ORs=1.01-1.23).

Conclusions: Adults with type 2 diabetes have substantial comorbidities. The leading MCC cluster is hypertension and hyperlipidemia only. Not only a higher number of comorbidities, but certain MCC clusters, such as hypertension and hyperlipidemia plus CAD and/or CKD, are associated with more readmissions and ER visits.

Implications for Policy, Delivery, or Practice: To date single-disease frameworks, including diabetes guidelines, do not sufficiently account for MCCs and, importantly, do not detail how these comorbidities may affect treatment plans and patient outcomes. Most diabetes outcomes research has focused on disease-specific measures but ignored how MCCs affect broader health outcomes (e.g., readmissions, ER visits) that can have important consequences. Our analysis highlights important comorbidity clusters to be addressed in guidelines. Specific MCC clusters should be targeted by tailored prevention programs in order to reduce diabetes costs and improve quality.

The Future of Chronic Care through the Glasses of a National Position Paper
Dominique Paulus, Belgian Health Care Knowledge Centre; Koen Van den Heede, Belgian Health Care Knowledge Centre; Sophie Gerkens, Belgian Health Care Knowledge Centre; Anja Desomer, Belgian Health Care Knowledge Centre; Raf Mertens, Belgian Health Care Knowledge Centre

Presenter: Dominique Paulus, M.D.,Ph.D,MSc., Senior Expert Physician, Belgian Health Care Knowledge Centre, dominique.paulus@kce.fgov.be

Research Objective: This paper presents the development and content of a national position paper for chronic care. Health care systems are now at a turning point with an urgent need to develop better care for the chronically ill instead of focusing on acute conditions in hospital settings.

Study Design: The position paper is based on various data sources: (1) publications from international organizations; (2) chronic disease plans from Pennsylvania, Québec, Denmark and The Netherlands; (3) scientific literature on patient empowerment and on new functions for healthcare professionals; (4) description of the Belgian initiatives and; (5) consultation of more than 100 stakeholders.

Population Studied: The target population are the chronically ill who have medical, social or other needs in relation to their illness. This approach differs from the usual disease-oriented initiatives.

Principal Findings: The position paper on chronic care proposes 20 recommendations subdivided into 50 concrete actions. First, routine care of high quality in outpatient settings: the starting point is an individualized care plan, based on the patient’s life goals and designed in collaboration with the multidisciplinary primary care team. One prerequisite is the access to the electronic medical record (EMR) for all care providers. Action points further relate to the attractiveness of primary health care professions, task delegation and development of new functions in primary care. Complex situations call for the intervention of a case manager and for collaborations between providers from the medical and social worlds. Second, seamless care between the first line of care and specialized services: specialized services play a key role in the initial diagnosis
and in the care for exacerbations or complications. They can assist the primary care team for pathology-related questions. Sharing the EMR and interventions by a discharge manager should favor a seamless transition between settings.

Third, empowering patients and informal caregivers: they need accurate, relevant and timely information by trained professionals in order to fulfill their new role as partners in chronic care. Financial and logistical support of informal caregivers, including respite care and adaptation of the living environment should contribute to maintaining the patient at home when possible.

Finally, recommendations advocate the set up of a quality system, harmonization between coordination structures, accessibility, equity and payment systems that reward integrated care of high-quality.

**Conclusions:** This project shows the numerous action points to be implemented in order to reorient a health care system towards the needs of the chronically ill.

**Implications for Policy, Delivery, or Practice:** A new orientation of health care systems towards chronic care calls for changes in multiple domains (human resources, financing, quality) and in particular investments in the first line of care. This dynamic reform should be continuously monitored and adapted to the constantly changing patient needs, societal values, healthcare system, budgetary resources and scientific knowledge.

**Meaningful Activity Participation of Older Adults with Cancer**

Mackenzi Pergolotti, University of North Carolina, Chapel Hill

**Presenter:** Mackenzi Pergolotti, M.S. OTR/L, Pre-doctoral Fellow, Cecil G Sheps Center for Health Services Research, University of North Carolina, Chapel Hill, pergolot@email.unc.edu

**Research Objective:** Participation in activity that is personally meaningful leads to improved emotional and physical well-being and quality of life. However, little is known about the degree to which older adults with cancer participate in activity that they rate to be personally meaningful and how that relates to clinical and demographic factors. The objective of this study was to examine meaningful activity participation of older adults with cancer.

**Study Design:** We recruited adults 65+ with a diagnosis of cancer from a large academic medical center outpatient oncology clinic in the Southeast for a cross-sectional study examining meaningful activity participation. Measures included a brief geriatric assessment with demographic questions, Karnofsky Performance Status Tool and a Timed "Up and Go" Test. We also included patient reported subscales of the following instruments: an IADL subscale from the Multidimensional Functional Assessment Questionnaire: Older American Resources and Services, and an ADL subscale from the Medical Outcomes Study- Physical Health and scores from the Meaningful Activity Participation Assessment (MAPA). The MAPA was designed in order to assess an older person’s personal meaning of activity participation, weighted by their frequency (Eakman, 2010). We used multivariate regression to examine the relationship between risk factors for decreased quality of life (age, sex, race, marital status, education & functional ability) and MAPA scores.

**Population Studied:** Patients were included, who had an appointment at the outpatient oncology clinic that were ≥65 years of age, and gave consent to complete the Geriatric Assessment and MAPA. Patients were excluded if they did not have a cancer diagnosis, and if they did not read English. A total of forty-nine adults formed the study sample.

**Principal Findings:** Preliminary findings suggest higher levels of education and functional ability was significantly associated with higher scores on the MAPA. The mean MAPA score was 446 and it ranged from 208-63. Higher scores on the MAPA are related to better psychological well being and mental health. The average age was 73 years with a range from 65-89 years, 51% of the sample was female and 78% White, all with a diagnosis of cancer. 27% of the patients were diagnosed with breast cancer, followed by lymphoma (13%) and lung cancer (13%). 73% reported at least some college education, 87% were retired, 57% were married and 42% lived alone.

**Conclusions:** Education and level of functional status are significantly related to meaningful activity participation. To our knowledge, this is the first study to examine the relationship between patient-reported meaningful activity participation and clinical and demographic factors of older adults with cancer.
Implications for Policy, Delivery, or Practice: Examining the degree of meaningful activity participation of older adults with cancer will inform future research towards improving the survivorship care provided through engaging patients in empirically based treatments they find personally meaningful and that are aimed at improving their quality of life.

Implementation and Initial Validation of a Tool, Minnesota Edinburgh Complexity Assessment Method, to Assess Patient Complexity within a Primary Care Based Preventative Screening Program in Scotland

Rebekah Pratt, University of Minnesota; Carina Hibberd, University of Stirling, Scotland; Isobel Cameron, University of Aberdeen, Scotland; Stewart Mercer, University of Glasgow, Scotland; Margaret Maxwell, University of Stirling, Scotland

Presenter: Rebekah Pratt, Ph.D., Assistant Professor, University of Minnesota, rjpratt@umn.edu

Research Objective: The Minnesota Edinburgh Complexity Assessment Method (MECAM) is a tool to assess complex patients in primary care. MECAM has four key domains, being, health and wellbeing, social environment, health literacy and communication. This study researched the implementation of MECAM in Keep Well, a Scotland wide preventative care program targeting low income patients at risk of coronary heart disease. The main objective was to develop and establish face validity of the MECAM, specifically in its ability to identify mental health-related needs. Secondary aims were to conduct preliminary external validity testing of the MECAM; establish how best to integrate the MECAM into existing health checks and; evaluate the implementation and perceived value of MECAM.

Study Design: This mixed methods prospective cohort study undertook face validation testing, conducted preliminary external validity testing, piloted implementation, and conducted a case study in a population of known complexity.

Three sites in Scotland participated. Completed data were collected for 243 patients from underserved populations.

Population Studied: Keep Well is delivered by nurses based in General Practitioner clinics, in Scotland. Nurses collected data for 286 low income patients at baseline and 243 patients post implementation. Additionally, a case study on use with homeless and gypsy traveler patients was also conducted.

Principal Findings: Face validation was established for use with nurses in primary care in Scotland. MECAM did not impact patient satisfaction, but did lead to increased referral to a broader range of services, particularly to those addressing psychological, social and lifestyle needs. Nurses valued MECAM and found it easy to implement. Partial external validation was established in relation to the SF-36. The time taken to complete was acceptable in the context of this screening program. MECAM worked well in populations of known high complexity.

Conclusions: MECAM offers much promise as an assessment of complexity that identifies biopsychosocial complexity, and supports clinician decision making to address those needs. MECAM was well accepted by clinicians and implemented successfully. MECAM appears to offer good potential to support collaborative and integrated consultations, and may increase the referral of patients to a wider range of resources.

Implications for Policy, Delivery, or Practice: Clinicians participating in the study agreed that use of the MECAM encouraged a more comprehensive assessment of patient needs (physical, mental and social). MECAM also demonstrated that it may broaden referrals in response to patient needs. This highlights the potential of MECAM to contribute to better understanding patient needs, both at an individual and patient population level. This may have important implications for how care is delivered, particularly through assisting with the identification of non-medical needs which may routinely interfere with care. Additionally, the role of such assessments in current health initiatives in primary care, such as the medical home, warrants further exploration as a tool which may enhance team approaches to care. The role of such tools in supporting policy level initiatives to better understand the assessment of level of complexity, payer models by complexity and risk assessments, such as in relation to readmissions, should be reviewed.
The Nexus of Traumatic Brain Injury and Mild Cognitive Impairment

Mary Jo Pugh, South Texas Veterans Health Care System; Carlos Jaramillo, South Texas Veterans Healthcare System; Blessen Eapen, South Texas Veterans Healthcare System; Jacqueline Pugh, South Texas Veterans Healthcare System; Thomas Kent, Michael E. DeBakey VA Medical Center, Houston; Gustavo Roman, Methodist Hospital, Houston

Research Objective: TBI is the signature injury of the wars in Afghanistan and Iraq, with a majority being mild TBI (mTBI). TBI may cause MCI and is associated with increased risk of neurodegeneration, highlighting a need for accurate early diagnosis and appropriate follow-up of TBI patients. MCI is a useful concept for early symptomatic diagnosis of Alzheimer’s disease; however, no studies have examined the link between TBI severity and MCI, nor the contributing effect of PTSD to cognitive loss in TBI. We tested the hypothesis that severity of traumatic brain injury (TBI) is associated with mild cognitive impairment (MCI) controlling for post-traumatic stress disorder (PTSD).

Study Design: This retrospective database study used diagnostic data (ICD-9CM codes) from the Department of Veterans Affairs (2010-2011) to identify individuals with TBI and MCI using validated algorithms. TBI was classified as penetrating (pTBI), severe, moderate, or mild (mTBI) based on the most severe type coded. To address potential confounding with PTSD we created a TBIxPTSD interaction term, and used logistic regression analysis to examine the odds of TBIxPTSD categories associated with MCI compared to those without TBI or PTSD.

Population Studied: Veterans of Afghanistan and Iraq wars who received VA care in both FY10 and FY11.

Principal Findings: Of the 303,716 individuals who received VA care in 2010-2011, 2,155 (0.71%) were diagnosed with MCI. The odds of MCI diagnosis with pTBI+PTSD was lower than pTBI alone (albeit not significantly; 116.7; 95% CI 44.1-63.4 vs. 29.2; 95% CI 23.2-36.8 respectively; p<.001).

Conclusions: The relationship between MCI and TBI is strongest in more severe TBI, and for severe TBI comorbid PTSD was not significantly different than TBI alone. While MCI was also associated with mTBI alone, having comorbid PTSD conferred significantly higher odds of MCI. These data suggest that PTSD should be included in epidemiological study of mTBI and neurodegenerative disorders.

Implications for Policy, Delivery, or Practice: This significantly increased risk of mild cognitive impairment even among those with mTBI suggests that the VA healthcare system may need to provide training to patient aligned care teams regarding identification and treatment of MCI and consider expanding access to relevant specialty care (e.g., neurology, geriatrics/memor)

The Nexus of Traumatic Brain Injury and Dementia

Mary Jo Pugh, South Texas Veterans Health Care System; Carlos Jaramillo, South Texas Veterans Healthcare System; Blessen Eapen, South Texas Veterans Healthcare System; Jacqueline Pugh, South Texas Veterans Healthcare System; Thomas Kent, Michael E. DeBakey VA Medical Center, Houston; Gustavo Roman, Methodist Hospital, Houston

Research Objective: TBI is the signature injury of the wars in Afghanistan and Iraq, with a majority being mild TBI (mTBI). TBI may cause MCI and is associated with increased risk of neurodegeneration, studies linking mild TBI to dementia are limited and no studies have examined the contributing effect of PTSD to dementia in TBI. We tested the hypothesis that severity of traumatic brain injury (TBI) is

CI 40.9-333.4 vs 216.6; 95% CI 72.4-647.6; p>.1), in contrast to mTBI+PTSD, which was significantly higher than mTBI alone (52.9; 95% CI 44.1-63.4 vs. 29.2; 95% CI 23.2-36.8 respectively; p<.001).

Conclusions: The relationship between MCI and TBI is strongest in more severe TBI, and for severe TBI comorbid PTSD was not significantly different than TBI alone. While MCI was also associated with mTBI alone, having comorbid PTSD conferred significantly higher odds of MCI. These data suggest that PTSD should be included in epidemiological study of mTBI and neurodegenerative disorders.

Implications for Policy, Delivery, or Practice: This significantly increased risk of mild cognitive impairment even among those with mTBI suggests that the VA healthcare system may need to provide training to patient aligned care teams regarding identification and treatment of MCI and consider expanding access to relevant specialty care (e.g., neurology, geriatrics/memor)

Funding Source(s): VA

Poster Session and Number: B, #649
associated with dementia in Veterans from the Wars in Afghanistan and Iraq, controlling for potential confounding of post-traumatic stress disorder (PTSD).

**Study Design:** This retrospective database study used diagnostic data (ICD-9CM codes) from the Department of Veterans Affairs (2010-2011) to identify individuals with TBI and dementia using validated algorithms. TBI was classified as severe (includes penetrating), moderate, or mild based on the most severe type coded. We controlled for age, sex, race, and PTSD.

**Population Studied:** Veterans from the Wars in Afghanistan and Iraq, who received VA care in FY10 and FY11.

**Principal Findings:** Of the 303,716 individuals who received VA care in 2010-2011, 571 (0.2%) were diagnosed with dementia. The odds of diagnosis with severe TBI (205.6; 95% CI 90.0-470.1) was significantly higher than moderate (27.3; 95% CI 17.3-42.9) or mild (5.2; 95% CI 2.9-9.2; p<.001) TBI. PTSD diagnosis was associated with reduced odds of dementia (.41; 95% CI .27-.62). There was no significant interaction between TBI and PTSD.

**Conclusions:** As expected, the relationship between dementia and TBI is strongest in more severe TBI, but the association with mTBI remained significant after controlling for demographic characteristics. The impact of mTBI remained the same after controlling for PTSD. Unlike prior analyses that found an interaction between mTBI and PTSD for cognitive impairment, and there was no significant interaction between TBI severity and PTSD for dementia.

**Implications for Policy, Delivery, or Practice:** While the number of individuals affected is small at this time, 10-20% of Veterans of the Afghanistan/Iraq wars have TBI exposure, and the average age of those patients was 36 in FY11. Patient aligned care teams may benefit from training to identify patients with cognitive decline early in order to provide treatments which may delay the onset of more severe dementia symptoms.

**Health Care Costs and Service Use Among Privately Insured Individuals with Autoimmune Conditions Treated with Specialty Medications**

Naomi Sacks, Boston University, School of Public Health; Terese Condon, MBA, IMS Health Payer Solutions

**Presenter:** Naomi Sacks, PhD, Senior Analyst, IMS Health Payer Solutions, Health Policy and Management, Boston University, School of Public Health, nsacks@bu.edu

**Research Objective:** Identify correlated variations in health care expenditures and service use among privately insured individuals with auto-immune conditions treated with specialty medications.

**Study Design:** IMS LifeLink Health Plan Claims Database data used to estimate plan allowed annual per patient spending and utilization rates. Calendar year 2010 and 2011 claims for health plan members under age 65 used to identify auto-immune condition patients in 2010, and cost and utilization estimates generated for 2011. Treatment settings defined using diagnosis (ICD-9), place of service (POS), revenue, and CPT codes.

**Population Studied:** 6.9 million members with 24 months of continuous enrollment were identified in 19 health plans across the United States. A subset of 107,519 was identified with HIV/AIDS (N=8,512), Crohn’s Disease (N=11,529), Multiple Sclerosis (N=10,613), Psoriasis (N=26,661), Psoriatic Arthropathy (N=4,886), Rheumatoid Arthritis (N=39,369) and/or Ulcerative Colitis (N=12,115).

**Principal Findings:** Mean annual per patient spending, $18,257 (vs. All Members: $4,076), ranged from $10,803 (Psoriasis) to $17,919 (Rheumatoid Arthritis), $26,409 (HIV/AIDS) and $35,157 (MS). Spending was distributed across inpatient ($17,907; 15%) outpatient ($7,432; 41%) services and retail pharmacy ($8,104; 44%) settings (vs. All Members: 20%, 59%, 21%). Retail pharmacy was approximately 2/3, and inpatient a much smaller proportion of HIV/AIDS (Rx: 66% IP: 11%) and MS (Rx : 64%; IP: 8%) spending; outpatient and inpatient were higher proportions for Crohn’s Disease (OP: 50%; IP: 21%) and Ulcerative Colitis (OP: 49%; IP: 24%) expenditures. Retail pharmacy specialty medication spending was over 2/3 of all pharmacy spending ($5,576; 68%; vs. All Members: $167; 4%), represented 52% of retail pharmacy specialty prescription medication across the 6.9 million study sample plan members, but varied by condition, ranging from $4,237 (Ulcerative Colitis; 22%) to $11,048 (Psoriatic Arthropathy; 79%) to $17,485.
prescriptions annually, at a mean per prescription cost of $214, with 4.4 for specialty medications, at $1272 mean cost per prescription (vs. All Members: 12.45; $69; $811). Annual per patient specialty medication prescriptions, and per prescription costs, ranged from 1.23/$770 (Ulcerative Colitis) to 4.85/$806 (Rheumatoid Arthritis) to 6.05/$3,169 (MS). Over half (2.73) of RA patient specialty prescriptions were for generics ($66/per Rx); nearly all MS specialty prescriptions (5.8; 96%) were for branded medications. Specialty medications administered in outpatient settings ($1,298; 7% of all spending; vs. All Members: $107; 4%), combined with retail pharmacy dispensed specialty medications, were 38% of all spending ($6,874 vs. All Members: $275; 7%) and ranged from 15% (Ulcerative Colitis) to 26% (Crohn’s) to 55% (HIV/AIDs) and 60% (MS).

Conclusions: Specialty drug prescriptions and specialty drugs administered in outpatient settings contribute substantially to expenditures for auto-immune condition patients. Compared to all members, inpatient and outpatient service spending were smaller proportions of all expenditures, but were relatively higher proportions for Crohn’s Disease and Ulcerative Colitis patients.

Implications for Policy, Delivery, or Practice: Improved coordination and ongoing analysis of specialty drug treatment costs, use and benefits across medical and pharmacy benefits and care settings could improve care access and cost management. Prior authorization and cost sharing incentives for optimal site of care may also improve access and cost management.

Poster Session and Number: B, #651

The Role of Limited English Proficiency in Health Care Use of Those with Chronic Conditions: Findings from California’s Low Income Health Program

Erin Salce, UCLA Center for Health Policy Research; Erin Salce, UCLA Center for Health Policy Research; Nadereh Pourat, University of California, Los Angeles; Xiao Chen, UCLA Center for Health Policy Research; Dylan Roby, University of California, Los Angeles

Presenter: Erin Salce, M.P.H., Senior Research Associate, UCLA Center for Health Policy Research, erin.salce@ucla.edu

Research Objective: The objective of this study is to assess variations in utilization patterns of chronically ill Low Income Health Program (LIHP) enrollees by limited English proficiency (LEP). LIHP is a county-operated Medicaid Waiver demonstration program which expands coverage to eligible low income adults effective July 1, 2011 through December 31, 2013. Under the Affordable Care Act (ACA), LIHP enrollees will transition to California’s Medi-Cal Program or to California’s Health Benefit Exchange. The delivery of care to those with chronic conditions and LEP can be more challenging and would require culturally competent care coordination and management services. The safety net providers participating in the LIHP program deliver such services.

Study Design: We used claims and enrollment data from 12 participating counties and a consortium of 35 rural counties. Over 500,000 individuals enrolled in LIHP during the first program year were included in the analysis. Preference for communication in a language other than English was used as a proxy for LEP status. Sex, age, federal poverty level (FPL), county and a chronic condition indicator were used in logistic models of use. Chronic conditions included diabetes, asthma and chronic obstructive pulmonary disease, cardiovascular disease and congestive heart failure, dyslipidemia, and hypertension. Services examined included use of any inpatient, emergency room (ER), and outpatient evaluation and management (E&M) visits during the program year.

Population Studied: Adults between 19 and 64 years of age enrolled in the county-operated Low Income Health Program, a Section 1115 Waiver demonstration which provides health care coverage to individuals who are not eligible for Medicaid and have incomes below 200% FPL.

Principal Findings: Compared to non-LEP enrollees, LEP enrollees were more likely to be female, over the age of 55, and have a diagnosis of diabetes, dyslipidemia, or hypertension. Over 30% of LIHP enrollees with a chronic condition were LEP, with 70% of LEP enrollees preferring Spanish, 23% preferring Asian American languages, and 7% preferring another language. Those with chronic conditions had higher rates of E&M, ER, and inpatient visits. However, those with LEP and chronic conditions had a significantly higher likelihood of E&M visits (OR=1.5) than non- LEP (OR=1.1), after controlling for sex, age, FPL, chronic
conditions and variations in county implementation of the LIHP. In contrast, those with LEP and chronic conditions had a lower likelihood of ER (0.6 vs. 0.7) and inpatient (0.6 vs. 0.7) visits.

Conclusions: The higher rates of E&M visits and lower use of ER and inpatient care among chronically ill and LEP LIHP enrollees may be due to better culturally competent primary care visits which in turn contributed to lower use of more costly emergency and inpatient services.

Implications for Policy, Delivery, or Practice: The effectiveness of care delivery under the Medicaid expansion and Health Benefit Exchange programs may be improved with additional effort to improve delivery of culturally concordant care coordination and management care. English proficiency and language preference can play a significant role in the service use of chronically ill populations. These findings highlight how the care of chronically ill populations can be more successfully managed.

Poster Session and Number: B, #652

Ambulatory Care Sensitive Conditions and 30 Day Hospital Readmission for Adults with Diabetes
Arlene Smaldone, Columbia University; Christie Y. Jeon, ScD, UCLA Fielding School of Public Health

Research Objective: The purpose of this study was to describe the rate of 30 and 90 day hospital readmission with ambulatory care sensitive conditions (ACSC) among adults with diabetes and identify independent factors associated with ACSC hospital readmission.

Study Design: We conducted a retrospective cohort study of adult patients hospitalized with a principal (PDM) or secondary diagnosis of diabetes (SDM). Data were drawn from the Clinical Data Warehouse of a tertiary referral hospital in northern Manhattan. ICD9 codes 250.xx at the index hospital admission informed PDM or SDM. ACSC was defined as the Agency for Healthcare Research and Quality’s Prevention Quality Indicators with focus on 12 of 14 indicators relevant to adults with diabetes.

We compared 30 and 90 day readmission rates by DM status (PDM, SDM, without diabetes) at the index hospitalization by chi-squared test. We computed frequency of ACSC as a reason for readmission for each category and examined associations between DM status and ACSC readmission using univariable and multivariable logistic regression models controlling for demographic (age, gender, race/ethnicity), payer, and clinical factors (hospital length of stay [LOS], distance to the hospital [estimated as distance from the centroid of patient zip code to the hospital], renal failure, dialysis, surgery lasting 30 minutes or longer, severity of illness [graded by 3M All Patient Refined Diagnosis Related Groups] and mean blood glucose level) identified at the index hospital admission.

Population Studied: Adults with PDM or SDM hospitalized at a large tertiary care facility in northern Manhattan between January 1, 2006 and December 31, 2008 were studied. Hospitalizations for pregnancy and their associated conditions were excluded.

Principal Findings: Of 68,622 patients (1,365 PDM; 14,142 SDM; 53,115 without DM) meeting inclusion criteria, 6,674 (9.7%) and 11,495 (16.8%) patients were readmitted within 30 and 90 days respectively. Stratified by age and DM status, 30 day readmission rate was higher for PDM compared to SDM and without diabetes in both patients >=65 years (17% versus 13%, 11%) and <65 years (13% versus 11%, 8%). ACSC accounted for a greater proportion (92%) of 30 day readmissions for PDM compared to that of SDM (15%) and without DM (9%).

Controlling for demographic, payer and clinical factors, ACSC readmission was more likely for PDM patients who had received dialysis (aOR 2.3, 95% CI 1.1-4.7), a surgical procedure (aOR 2.2, 95%CI 1.3-3.7) or had higher severity of illness (aOR 5.2, 95% CI 1.4-19.1) at the index hospitalization whereas SDM readmitted for ACSC were more likely to be male (aOR 1.4, 95% CI 1.0-2.0), non Hispanic black (aOR 1.8, 95% CI 1.1-3.1), Hispanic (aOR 1.8, 95% CI 1.1-3.0) or had higher severity of illness (aOR 2.2, 95% CI 1.2-4.0) but less likely for surgical patients (aOR 0.4, 95% CI 0.2-0.6).

Conclusions: The risk of ACSC readmission was 6 times higher for PDM compared to both SDM and those without DM. Of interest, racial/ethnic disparity was not associated with readmission for PDM but predicted readmission for SDM. These results may inform early identification of DM patients for intervention at the index hospitalization to prevent avoidable hospital readmission.
Implications for Policy, Delivery, or Practice: Hospitalization for ACSC is avoidable and contributes to excess healthcare cost. Access to diabetes education at the index hospitalization to improve self-management knowledge and transition programs to facilitate connection with community based care at discharge is needed to reduce avoidable hospitalization for PDM and SDM at risk.

Chronic Condition Clusters that Predict Frequent Health Care Encounters among the Elderly

Jennifer St Sauver, Mayo Clinic; Veronique Roger, MPH, MD, Mayo Clinic; Barbara Yawn, MSc, MD, Olmsted Medical Center; Lila Rutten, MPH, PhD, Mayo Clinic; Jon Ebbert, MS, MD, Mayo Clinic; Wenjun Zhong, MPH, PhD, Mayo Clinic; David Warner, MD, Mayo Clinic; Walter Rocca, MPH, MD, Mayo Clinic

Presenter: Jennifer St Sauver, MPH, PhD, Associate Professor, Mayo Clinic; stsauver.jennifer@mayo.edu

Research Objective: Clinical care is frequently targeted toward management of isolated disorders. However, to optimize health care coordination, it is critical to identify groups of conditions associated with high utilization. The purpose of this study was to identify morbidity clusters associated with frequent health care encounters in individuals >= 65 years of age.

Study Design: We obtained all International Classification of Diseases, ninth revision (ICD-9) codes received in 2005-2008 by the residents of Olmsted County, MN who were >=65 years old in 2009. ICD-9 codes were grouped into 257 Clinical Classification Codes proposed by the Agency for Healthcare Research and Quality. We examined the upper quartile of encounters in 2009 as the primary outcome (>=18 encounters). Patient encounters included contact with a health care provider for lab testing as well as provider care visits. Recursive partitioning was used to identify variables and interactions which predicted frequent health care encounters. Trees were pruned at the endpoints that contained <10% of the study population, and were summarized by odds ratios (OR) and 95% confidence intervals (CI) for each branch using logistic regression. The terminal nodes were similar for men and women, so only overall results are reported.

Population Studied: Residents of Olmsted County, MN who were >=65 years old in 2009 (9,803 women and 7,533 men), and had granted permission for their medical information to be used for research (98% of the population in this age range).

Principal Findings: We identified three groups associated with frequent health care encounters 1) other aftercare (OR: 2.20, 95% CI: 2.01, 2.41); 2) cardiac dysrhythmia and other aftercare (OR: 5.15, 95% CI: 4.67, 5.69); 3) cardiac dysrhythmia, other aftercare, and other heart disease (OR: 11.77, 95% CI: 10.36, 13.36). The control group included all subjects with no other aftercare. The predominant ICD-9 codes in the other aftercare group were V58.61 “long-term use of anti-coagulants” (69%), V58.69 “long-term use of other medications” (6%) and V58.83 “therapeutic drug monitoring” (5%).

Conclusions: We examined all possible ICD-9 diagnostic codes over four years in an elderly Midwestern population. When all conditions were considered, persons with cardiac dysrhythmia, monitoring therapeutic drugs (particularly anticoagulants), and nonspecific heart disease codes had the highest number of health care encounters. Efforts are now needed to identify the underlying “mechanisms” responsible for these results (e.g., indications for, management of, and complications for anticoagulation therapy in heart disease patients).

Implications for Policy, Delivery, or Practice: Identification of such combinations of conditions is important to develop chronic disease management guidelines for people with multiple morbidities to reconcile contradictory recommendations, to help reduce complications, and to decrease costs of care.

Patients with Co-occurring Hypertension, Obesity, and Depression: Who Receive Diagnoses and Treatments? Is Treatment of One Condition Associated with Changes in Other Conditions?

Ming Tai-Seale, Palo Alto Medical Foundation Research Institute; Caroline Wilson, Palo Alto Medical Foundation Research Institute; Jun Ma, Palo Alto Medical Foundation Research Institute; Hal Luft, Palo Alto Medical Foundation Research Institute
Research Objective: Hypertension, obesity, and depression are three leading causes of disability, with substantial impacts on individuals and the public. Research on them as co-occurring chronic conditions often relies on Medicare claims, which may underestimate their true burden. We used electronic health record (EHR) data from a large multispecialty practice to examine the number of people with these conditions by age category. We also assessed the probability that previously untreated patients would receive antihypertensives and examined the impact of such treatment on health outcomes in people with the other comorbidities (obesity and depression).

Study Design: Observational study using EHR data between 2002 and 2010. Besides descriptive analyses, we used multilevel modeling to examine trends in blood pressure (BP) and body mass index (BMI) over time, and to examine the relationship between hypertension treatment and BMI/BP trajectories, controlling for patient, physician, and clinic-level factors. We used propensity score stratification to reduce treatment selection bias.

Population Studied: Approximately 162,000 patients from a multispecialty group practice identified as overweight/obese, hypertensive, and/or depressed between 2002 and 2010.

Principal Findings: The majority of people with at least two of the three multiple chronic conditions (MCC) (71%; 23,806 of 33,326) were younger than 65 years. Many people are not formally diagnosed: only 53% (14,254 of 27,016) of obese patients based on BMI had a weight-related diagnosis. About 62% (34,945 of 56,111) of patients with high BP were diagnosed and/or treated for hypertension. Among high BMI patients, the odds of having a weight diagnosis is 20% higher if they have depression, and 40% higher if they have hypertension. Even controlling for frequency of visits, the co-occurring depression and overweight was associated with an increasing BMI growth trajectory (coeff=0.06, p<.001), whereas co-occurring depression, overweight, and hypertension was associated with a decreasing BMI growth trajectory (coeff=-.04, p<.01). Propensity score stratification method enabled us to find that antihypertensive treatment was associated with slower increase in BMI (coeff=-0.05, p<0.05) among patients with the highest propensity to receive hypertension treatment. Missing patient-reported mental health data prevented us from examining the propensity of antidepressant treatment, unfortunately.

Conclusions: The burden of depression, obesity, and hypertension is substantial. A high proportion of patients with weight problems were not formally diagnosed as such, but having co-occurring depression or hypertension increased their odds of getting a diagnosis for weight problem. Overweight patients with depression had faster rises in BMI whereas overweight patients with hypertension had slower rises in BMI. Treatment for hypertension was associated with slower BMI growth, regardless of whether they were also depressed.

Implications for Policy, Delivery, or Practice: Obesity and hypertension (and we suspect depression) are often under-recorded. Having multiple conditions, however, appears to lead to more accurate recording of diagnoses, independent of the number of visits. BMI trajectories over time are affected by the constellation of co-morbidities and associated treatments. The EHR is valuable for MCC research because it captures both what is recorded as a diagnosis on a bill and on problem list which can be more than what is in Medicare claims. Collecting patient-reported mental health data in EHR will make it even more powerful.

Funding Source(s): AHRQ

Are Caregivers in Poor Health Able to Effectively Facilitate Access to Preventive Care in Dependent Older Adults?

Joshua Thorpe, University of Pittsburgh School of Pharmacy; Carolyn Thorpe, University of Pittsburgh School of Pharmacy; Richard Schulz, University of Pittsburgh Center for Social and Urban Research

Research Objective: Effective caregiving for a dependent older adult with complex medical needs is challenging. Dependent older adults often have extensive disease-specific and preventive care needs. Therefore, one of the greatest caregiving challenges is coordinating patient care and facilitating access to health
services. The burden of these responsibilities takes a toll on caregiver health, and many caregivers juggle their own complex medical needs alongside those of the patient. However, very little is known about how caregiver health impacts their ability to obtain recommended health services for their care-recipient. The purpose of this study was to examine the relationship between informal caregiver physical and mental health and receipt of recommended preventive care in dependent older adults.

**Study Design:** We pooled data from the 2000-2008 Medical Expenditure Panel Survey (MEPS), a nationally representative survey of non-institutionalized US households, to identify care-recipient/caregiver dyads. Older care-recipients were identified as respondents aged 65+ receiving IADL or ADL help who remained in the community for the entire year. Primary informal caregivers were identified as per two criteria: 1) resides in a household with an identified care-recipient, and 2) self-identified as the most knowledgeable of the health of all household members and therefore served as the MEPS household respondent. Sensitivity analyses were conducted using more restrictive definitions of primary caregiver status (e.g., restricting to households with only 2 members: care-recipient and MEPS household respondent) and results were robust. We examined a range of dichotomous indicators of preventive service use as dependent variables (flu shot; blood pressure check; cholesterol check; colon and breast cancer screening; dental examination). Key caregiver health variables included number of chronic conditions; SF-12 physical health; SF-12 mental health; and caregiver self-reported memory problems. All models were adjusted for patient predisposing, enabling, and medical need variables. Survey-weighted logistic regression models were used to examine the relationship between caregiver health variables and care-recipient receipt of preventive care.

**Population Studied:** U.S. civilian non-institutionalized older adults receiving ADL/IADL assistance and their co-residing informal caregiver.

**Principal Findings:** The sample included 1,491 care-recipient/caregiver dyads, representing nationally an average of 4.47 million dyads in the community per year. According to nested likelihood ratio testing, caregiver health variables were jointly significant predictors in all models of care-recipient preventive use. Adjusting for all care-recipient variables, poorer caregiver mental health was associated with a decreased likelihood of 3 of 6 preventive services (blood pressure, mammogram, dental exam), and poorer physical health was associated with 4 of 6 (blood pressure, flu shot, colon cancer, dental exam). The relationship between caregiver number of chronic conditions and preventive service use was complex and non-linear. Having a caregiver with no conditions (compared to only 1 condition), or with multiple conditions, were risk factors for non-receipt of several preventive services.

**Conclusions:** Informal caregivers burdened by their own impairments and complex health issues may face challenges in facilitating access to preventive care in dependent older adults.

**Implications for Policy, Delivery, or Practice:** Results from this study suggest that policies and interventions designed to support the health of informal caregivers are critical to the success of community-based models of care and older adult’s ability to age in place.

**Preventable Hospitalizations in Patients with Diabetes and Chronic Kidney Disease**

Chin-Lin Tseng, Center for Healthcare Knowledge Management; Orysya Soroka, Department of Veteran Affairs- New Jersey Healthcare System; Jean-Philippe Lafrance, University of Montreal; Miriam Maney, Department of Veteran Affairs- New Jersey Healthcare System; Leonard M Pogach, Department of Veteran Affairs- New Jersey Healthcare System

**Presenter:** Chin-Lin Tseng, Dr.P.H., Health Research Scientist/Assistant Professor, Center for Healthcare Knowledge Management/Departernent, Center for Healthcare Knowledge Management, chin-lin.tseng@va.gov

**Research Objective:** Preventable hospitalizations (PHs) can be prevented by timely and effective ambulatory care. This study aimed to assess rates of PHs in patients with diabetes and chronic kidney disease (DM-CKD). The PHs included nine Agency for Health Research and Quality Prevention Quality Indicators and three additional ones relevant to this population.

**Study Design:** Serial cross-sectional cohort study. We used both VHA and Medicare data files to calculate annual age- and sex-standardized rates of the 12 PHs (in per 1,000)
and derived percent of five-year rate change. The standard population used for age and sex adjustment was the first cross-sectional cohort (fiscal year (FY) 2000).

Population Studied: We assembled serial cross-sectional cohorts of veterans who received health care in the Veterans Health Administration (VHA) system and had DM-CKD in FYs 2000-2004.

Principal Findings: The study cohort increased from 155,081 in FY2000 to 255,638 in FY2004. They were 67.5±10.1 years old in FY2000 to 68.3±10.0 in FY2004, mostly men (97.4%-97.6%) and Whites (80.7%-83.5%); 31.8%-32.9% had stage 3-5 CKD. Overall, the rate of any PH was 103.1 in FY2000 and 73.7 in FY2004, a 28.5% decrease. Consistently over the years, hear failure (35.5-23.3 per 1,000 in FYs 2000-2004) and acute kidney disease (AKI; 32.6-25.3) were the top 2 PHs; lower extremity ulcers (1.0-0.6) and hypertension (1.7-1.3) were the lowest two. By category, the PH rates from high to low were cardiovascular (hypertension, heart failure, angina without procedure; 43.7-27.1 in FYs 2000-2004), AKI (32.6-25.3), infections (pneumonia, urinary tract infection; 20.3-15.8), metabolic decompensation (short term, uncontrolled diabetes, dehydration, hypoglycemia; 13.7-9.5), and lower extremity (amputations, ulcers; 6.1-3.3). For individual PH and PHs by category, there were downward trends of various degrees. Individually, the rate decrease ranged between 18.9% (pneumonia) and 62.3% (Angina without procedure). By category, decrease in rates from low to high were infections (22.1%), AKI (22.2%), metabolic decompensation (30.7%), cardiovascular (38.0%), and lower extremity (46.3%).

Conclusions: After adjusting for age and sex, there were 103.1 in FY2000 and 73.7 in FY2004 per 1,000 VHA veterans with DM-CKD who had any PH; the rate decreased 28.5% over the five years. Heart failure and AKI had the highest rates, and lower extremity ulcers and hypertension had the lowest ones. There seems to be consistent downward trends (of various degrees) in PHs in VHA patients with DM-CKD; the decrease in the PH rate ranged from 18.9% in pneumonia to 62.3% in Angina without procedure.

Implications for Policy, Delivery, or Practice: It is important to further evaluate changes in patient mixes as well ambulatory care over the years and their association with the rates of PHs to facilitate efforts in improving quality of care among this group of patients with complex chronic conditions.

Drug Overdose in a National Cohort on Opioid Analgesics: Effect of Depression, Antidepressants and Benzodiazepines

Barbara Turner, The University of Texas Health Science Center, San Antonio; Yuanyuan Liang, Department of Epidemiology and Biostatistics. University of Texas Health Science Center San Antonio and Center for Research to Advance Community Health (ReACH); Christopher Louden, Department of Epidemiology and Biostatistics. University of Texas Health Science Center San Antonio; Benjamin Ehler, Department of Epidemiology and Biostatistics. University of Texas Health Science Center San Antonio; KoKo Aung, Department of Medicine. University of Texas Health Science Center San Antonio and Center for Research to Advance Community Health (ReACH)

Presenter: Barbara Turner, M.D.,M.S.Ed., Professor Of Medicine, General Internal Medicine, The University of Texas Health Science Center, San Antonio, turner@uthscsa.edu

Research Objective: In a national cohort of patients with chronic non-cancer pain (CNCP), we examined associations with risk of drug overdose for opioid analgesic (OA) prescriptions (RXes) risk defined by dose and duration, benzodiazepine and anti-depressant Rxes.

Study Design: In this retrospective cohort study of Aetna’s national health maintenance organization (approximately 2.1 million enrollees annually), we identified 279,049 persons aged 18 to 64, enrolled >1 year from 1/2009 to 7/2012 who filled 2 or more RXes for non-injectable Schedule II or III OAs. In this group, exclusions (N=57,986) included: cancer diagnosis (not basal cell) within 6 months of an OA Rx, methadone or buprenorphine-naloxone for opioid dependence, and incomplete diagnostic or demographic data. Claims and enrollment data included: demographics (age, gender, US region), inpatient and outpatient encounters, ICD-9-CM diagnosis codes, and filled RXes for OAs, benzodiazepines, and anti-depressants. We created indicators from ICD-9 codes for 5 types of CNCP, depression, and anxiety disorder. For each 6-month interval from first OA Rx until last enrollment date or July 2012, we
defined 4 OA risk categories: NO risk (0 days), LOW risk (1-60d at <40 morphine equivalent daily dose in mg [MED]), MEDIUM risk (1-60d at 40-99 MED or >61d at <40 MED), HIGH risk (>100 MED or >60d at 40-99 MED). We also examined duration of benzodiazepine and antidepressant therapy. Our outcome was any encounter with the diagnosis of drug overdose within each 6-month interval. Using repeated measures logistic regression, we examined the adjusted association of OA risk with the outcome, adjusting for demographic and clinical variables as well as interactions of OA risk with benzodiazepines, antidepressants, anxiety, and depression.

**Population Studied:** The cohort of 221,063 privately insured persons aged 18 to 64 with at least 2 OA Rxes for CNCP was followed for 881,555 6-month intervals.

**Principal Findings:** The cohort is 57% female, median age 45 (IQR: 35-54) and residing in the South (47%), West (18%), Midwest (6%) and Northeast (29%). One or more overdose events occurred in 1469 6-month intervals. After adjustment, only patients with HIGH OA risk had higher (p=0.003) odds of drug overdose versus NO OA (adjusted odds ratio [OR]=1.28, 95% CI 1.09 to1.50). Duration of benzodiazepine therapy (days) was positively associated with overdose versus none: [1-30d: OR=1.72 (CI 1.44-2.05); 31-90d: OR=2.23 (CI 1.88-2.64); 91-180d: OR=2.65 (CI: 2.27-3.09)]. The ORs for overdose were also higher for persons on short-term (1-60d) antidepressants versus longer-term (61-180d) [OR=1.23; (CI 1.04-1.45); p=0.017] and versus no antidepressants [OR=1.69; (CI 1.44-1.98); p<0.001]. The only significant interaction was for depression diagnosis and antidepressants which showed a markedly increased odds of overdose for depression & 1-60d antidepressants versus no depression & no antidepressants [OR=18.32, (CI 14.93-22.47), p<0.001].

**Conclusions:** High dose OAs significantly increase the risk of drug overdose among persons with CNCP but the highest risk is for longer benzodiazepine use and depressed persons initiating antidepressant therapy.

**Implications for Policy, Delivery, or Practice:** Policies and clinical programs are needed to address the risks of drug overdose in persons with CNCP treated with OAs using benzodiazepines or initiating drug treatment for depression.

**Reliance, Continuity, and Quality of Primary Care in VA and Medicare Programs**

Matthew L. Maciejewski, PhD, Durham VA Medical Center; Virginia Wang, Durham VA Medical Center; James F. Burgess, Jr, PhD, 3Center for Organization, Leadership & Management Research, VA Boston Healthcare System; Chris L. Bryson, MD, MS, Northwest Center for Outcomes Research in Older Adults, Department of Veterans Affairs; Mark Perkins, PharmD, Northwest Center for Outcomes Research in Older Adults, Department of Veterans Affairs; Chuan-Fen Liu, PhD, Northwest Center for Outcomes Research in Older Adults, Department of Veterans Affairs

**Presenter:** Virginia Wang, Ph.D., M.S.P.H., Investigator, Center for Health Services Research in Primary Care, Durham VA Medical Center, virginia.wang@duke.edu

**Research Objective:** Continuity of care is considered a critical characteristic of high-performing health systems, because receiving care from a single provider has been strongly associated with better care experiences, fewer emergency room visits and fewer hospitalizations. Most prior studies have examined continuity of care within a single health care system. Patients who have access to and obtain services in multiple health care systems, such as Medicare-eligible veterans enrolled in the VA Health Administration, may experience care discontinuity and undermine quality of care. The objective of this study was to examine whether quality of diabetes care was associated with continuity of care or veterans’ VA reliance for primary care.

**Study Design:** Retrospective cohort study of Medicare-eligible veterans enrolled in the VA with diabetes in 2001-2004. Using VA administrative and Medicare claims data, we examined under-provision, guideline-concordant provision, and over-provision of HbA1c testing, microalbumin testing and eye exams using ordered logistic regressions. We tested the predictive power of continuity of primary care provider (i.e., Modified Modified Continuity Index) and VA reliance for primary care (i.e., VA-only, Medicare-only, or Dual-system use), controlling for patient characteristics and time.

**Population Studied:** 1,867 Medicare-eligible veterans with diabetes.

**Principal Findings:** In 2001-2004, over half of these veterans with diabetes received primary care from a single provider (i.e., Modified Modified Continuity Index). VA reliance was strongly associated with better care experiences, fewer hospitalizations, and lower odds of diabetes-related hospitalization. The predictive power of continuity of care was modest but significant. The predictive power of VA reliance was stronger and significant for guideline-concordant provision of diabetes care, and modest but significant for under-provision of diabetes care and over-provision of HbA1c testing.
care in VA-only, approximately 25% sought primary care in Dual settings, and fewer received primary care in Medicare-only. Continuity of care was higher for Medicare-only users, VA-only users next, and lowest among Dual-system users. Under-provision of quality of diabetes care was common and over-provision was rare. Veterans who only obtained primary care in VA had higher rates of guideline-appropriate care than Medicare-reliant veterans or dual users. In adjusted analyses, veterans who relied only on Medicare for primary care were less likely to be over-tested for HbA1c and microalbumin (p<0.001) than veterans who relied only on VA for primary care. Dual users of VA and Medicare primary care were significantly more likely to be under-provided or over-provided HbA1c testing (p<0.001), microalbumin testing (p<0.001) and eye exams (p<0.05) than VA only users. Continuity of care was not associated with any diabetes quality of care metrics.

Conclusions: VA reliance was a stronger predictor of three diabetes quality processes for Medicare-eligible veterans in 2001-2004 than continuity of primary care.

Implications for Policy, Delivery, or Practice: The higher rates of guideline-appropriate care among veterans who only used VA primary care may be due in part to informational continuity that implicitly comes with the VA’s longstanding availability of a nationally accessible electronic health record (EHRs) that offsets discontinuity of provider care when veterans see different providers within the VA system. Wider adoption of EHRs should improve informational continuity within health systems to enable quality improvements that VA has realized through effective leveraging of EHR data.

In the Presence of a Mental Health Comorbidity, What Predicts Guideline Adherence for a Chronic Condition (Type 2 Diabetes)?
Lisa Welch, New England Research Institutes; Leigh H. Simmons, MD, Massachusetts General Hospital; David M. Pober, PhD, New England Research Institutes; Felicia L. Trachtenberg, PhD, New England Research Institutes; John B. McKinlay, PhD, New England Research Institutes and Massachusetts General Hospital

Presenter: Lisa Welch, Ph.D., Director, Center for Qualitative Research, New England Research Institutes, lwelch@neriscience.com

Research Objective: Evidence-based guidelines are often considered the standard for facilitating and assessing clinical care. Most guidelines are constructed for individual illnesses, but patients often present with multiple comorbidities. Little is known about how the presence of comorbidities affects guideline adherence. This study examines the predictors of guideline adherence for type 2 diabetes in the presence of a mental health comorbidity.

Study Design: A randomized balanced factorial experiment was conducted with physicians who observed video vignettes of an established patient presenting with type 2 diabetes with worsening glycemic control, weight gain, and elevated blood pressure. Vignette patients were systematically varied by age, gender, race, and comorbidity type (depression, schizophrenia with normal affect [SNA] or bizarre affect [SBA], and eczema as control). Verbal presentation was standardized. After viewing the vignette, respondents took part in a structured interview about clinical management, attitudes toward the patient, practice culture, disease management tool use, and professional satisfaction. The outcome (higher/lower adherence to diabetes guidelines) was scored on a 0-100 scale summing whether respondents would attend to constructs of published diabetes guidelines: diabetes treatment (glycemic control, self-management, psychosocial care); prevention/management of diabetes complications (cardiovascular disease, nephropathy, retinopathy, foot care/neuropathy); and additional physical and laboratory evaluations for comprehensive diabetes evaluation. A multivariate ANCOVA model with backwards elimination tested for significance of predictors and meaningful interactions with comorbidity, with control for potential confounders.

Population Studied: 256 primary care physicians

Principal Findings: The average level of guideline adherence was 43.6 (range: 3.0-92.5). Guideline adherence was significantly higher among physicians who reported using more disease management tools (p=.009) and general use of guidelines in their practice (44.9 vs. 36.5; p=.048). Compared to patients with eczema, guideline adherence was only 2.1 points higher for patients with depression (95%CI: -9.6,13.9)
but lower for patients with SNA (-4.0; 95%CI: -16.6,8.6) or SBA (-4.5; 95%CI: -16.3,7.4).

Further, for patients with SBA, physicians ranking schizophrenia higher than diabetes on their problem list exhibited somewhat lower adherence to diabetes guidelines compared to those ranking diabetes higher (-10.6; 95%CI: -18.9,-2.3); for patients with SNA, the trend was the same. Though physician view of patients' ability to self-manage health explained some of the difference in adherence among comorbidities (p=.02), the effect of comorbidity remained significant (p=.008). Professional satisfaction was not significantly associated with guideline adherence.

**Conclusions:** On average, respondents reported low adherence to diabetes guidelines in the presence of a comorbidity (mental health or eczema). That some physicians scored above 90 supports that the outcome variable captured relevant clinical actions, suggesting that low average adherence may reflect substantial clinical inertia. The finding of slightly lower guideline adherence in the presence of comorbid schizophrenia is consistent with literature showing that patients with serious mental illness risk lower quality of care and higher mortality from diabetes.

**Implications for Policy, Delivery, or Practice:**
Results identify two practice patterns—using more disease management tools and general use of guidelines in clinical practice—that support guideline adherence for patients with diabetes, providing actionable strategies that healthcare organizations and policymakers can target to enhance guideline implementation.

**Physician Styles of Clinical Management for a Chronic Condition (Type 2 Diabetes)**
Felicia L. Trachtenberg, PhD, New England Research Institutes; Lisa Welch, New England Research Institutes; David M. Pober, PhD, New England Research Institutes; John B. McKinlay, PhD, New England Research Institutes

**Presenter:** Lisa Welch, Ph.D., Director, Center for Qualitative Research, New England Research Institutes, lwelch@neriscience.com

**Research Objective:** Substantial research shows that variation in physician decision making contributes to healthcare disparities. Although several nonmedical factors (e.g., patient, physician, organizational characteristics) are known to affect physicians’ decisions, little is known about whether there are general styles of decision making (vs. singular clinical actions) or whether such styles may be applied differently depending on patient comorbidities. This study examines clusters of physician decision making styles for type 2 diabetes, overall and in the presence of a mental health comorbidity.

**Study Design:** A randomized balanced factorial experiment was conducted with physicians who observed video vignettes of an existing patient presenting with type 2 diabetes with worsening glycemic control, weight gain, and elevated blood pressure. Vignette patients were systematically varied by age, sex, race, and comorbidity type (depression, schizophrenia with normal affect [SNA] or bizarre affect [SBA], and eczema as control). Verbal presentation was standardized. Physician respondents were balanced by gender and more/less clinical experience (<=10 or >=21 years). After viewing the vignette, respondents took part in a structured interview about clinical management. Cluster analysis was performed using standardized residuals after accounting for any predicted differences based on the patient/physician characteristics in the study design.

**Population Studied:** 256 primary care physicians

**Principal Findings:** We identified three clusters depicting unique styles of diabetes management that were robust to controls for physician (gender and level of experience) and patient characteristics (age, sex, race, and comorbidity type). Compared to “middle of the road” physicians (N=84) in cluster 1, physicians in cluster 2 “interventionists” (N=88) were more likely to prescribe medications (e.g., antihyperglycemic, antihypertensive) or suggest referrals (e.g., nutritionist, ophthalmology). Physicians in cluster 3 “minimalists” (N=84) were less likely to perform exams (e.g., abdominal, head, neck, skin) or tests (e.g., chem. panel, liver function). A second cluster analysis was performed, without control for comorbidities. This analysis revealed a trend towards variation in the distribution of physician styles among clusters by comorbidity (p=0.13, chi-square test), with a significant difference in the distribution for those physicians who ranked schizophrenia higher on their problem list compared to diabetes (p=0.002, Fisher exact test). In this analysis, physicians ranking schizophrenia as the bigger problem were over-represented among the “minimalists” of diabetes care.
Hypertension is not well understood. We performed a study to determine the association between BMI category and overall mortality in hypertensive patients.

**Study Design:** We conducted a retrospective cohort study of patients in The Health Improvement Network (THIN) database to determine mortality risk for hypertensive patients in each BMI category. Hypertension was defined as the presence of a hypertension-related diagnosis code in the medical record. BMI was calculated from the first height and weight data recorded. A Cox proportional hazards survival model was used to account for confounders and censored data. The analysis was adjusted for age, sex, past history of diabetes or cardiovascular disease, smoking status, patient adherence to anti-hypertensive medications, socioeconomic status and other comorbidities as represented by the Charlson Comorbidity Index.

**Population Studied:** We identified 394,194 adult patients with previously diagnosed hypertension, recorded BMI data and follow-up of at least 1 year from the THIN database. Mean patient age was 57.3 years, and 52.9% of patients were female. Among all patients, 4,796 had BMI less than 18.5; 121,596 had BMI between 18.5 and 25; 160,610 had BMI between 25-30; 73,016 had BMI between 30-35; 34,176 had BMI greater than 35. Preexisting cardiovascular history (myocardial infarction, peripheral vascular disease, cerebrovascular accident, congestive heart failure or peripheral vascular disease) was present in 10.2% of patients.

**Principal Findings:** Compared to patients with BMI 18.5-25, having a BMI of 25-30 was associated with lower overall mortality risk (hazard ratio 0.90, p < 0.0001). Grade 1 obesity (BMI 30-35) was associated with a slight increase in mortality (hazard ratio 1.06, p = 0.0006). Increased mortality was associated with having a BMI less than 18.5 (hazard ratio 2.03, p < 0.0001) or greater than 35 (hazard ratio 1.38, p < 0.0001).

In subgroup analysis, being overweight was associated with lower mortality in smokers (hazard ratio 0.86, p < 0.0001) but not non-smokers (hazard ratio 0.97, p = 0.13).

**Conclusions:** In hypertensive patients, being overweight by BMI did not predict increased mortality. Grade 1 and higher obesity was associated with increased mortality, with greater risk at higher BMI categories. The protective
Effect of overweight BMI was present in smokers but not non-smokers.

**Implications for Policy, Delivery, or Practice:**
In clinical practice, it is common for providers to base recommendations for weight loss on elevated BMI. In the absence of additional clinical markers of metabolic mortality risk, an overweight BMI alone should not be used to guide weight loss recommendations in hypertensive patients, especially for patients with a history of smoking.

**Systolic Blood Pressure Targets and Cardiovascular Morbidity and Mortality in Patients with Hypertension**

Wenxin Xu, Harvard Medical School; Saveli I. Goldberg, Department of Radiation Oncology, Massachusetts General Hospital; Maria Shubina, Division of Endocrinology, Brigham and Women’s Hospital; Alexander Turchin, Division of Endocrinology, Brigham and Women’s Hospital

**Presenter:** Wenxin Xu, B.A., Medical Student, Harvard Medical School, wenxin_xu@hms.harvard.edu

**Research Objective:** Hypertension is the most common risk factor for cardiovascular events worldwide. Current guidelines recommend treating blood pressure to a goal of less than 140/90 mm Hg, but evidence that treating mild systolic hypertension improves outcomes is limited. We sought to determine the association between systolic hypertension treatment goals and cardiovascular risk.

**Study Design:** We performed a retrospective cohort study of patients in The Health Improvement Network (THIN) database to determine patient outcomes at various systolic blood pressure (SBP) treatment targets. Hypertension was defined as the presence of a hypertension-related diagnosis code in the medical record. SBP target was defined as the lowest blood pressure category at which anti-hypertensive medications were intensified. The primary composite outcome was defined as death or acute cardiovascular event (myocardial infarction, stroke, congestive heart failure, or peripheral vascular disease). Death from all causes and stroke served as secondary outcomes. A Cox proportional hazards survival model was used to assess time to outcome while adjusting for age, sex, baseline blood pressure, past history of diabetes or cardiovascular disease, smoking status, patient adherence to anti-hypertensive medications (as measured by medication possession ratio), socioeconomic status and other comorbidities as represented by the Charlson Comorbidity Index.

**Population Studied:** We identified 392,669 adult patients with previously diagnosed hypertension. Mean patient age was 57.3 years, and 53.0 percent of patients were female. Median follow-up time was 125 months; 15.3 percent of patients died or had an acute cardiovascular event during the follow-up period. Preexisting cardiovascular history (myocardial infarction, peripheral vascular disease, cerebrovascular accident, congestive heart failure or peripheral vascular disease) was present in 10.2 percent of patients.

**Principal Findings:** Compared to a SBP target of 140 mmHg or less, a SBP target of 130 mmHg or less was associated with increased risk of acute cardiovascular event or death (hazard ratio 1.09, p < 0.0001). SBP targets of 150 mmHg (hazard ratio 1.08, p < 0.0001) or greater were also associated with increased risk. In secondary analyses, a SBP target of 140 mmHg or less was associated with lower all-cause mortality compared to targets of 130 mmHg (hazard ratio 1.06, p = 0.0009) or 150 mmHg (hazard ratio 1.07, p = 0.0002). There was no significant difference in stroke risk between SBP treatment targets of 130 versus 140 mmHg (p = 0.28), though both strategies were superior to a target of 150 mmHg (hazard ratio 1.08, p = 0.0002). In all analyses, SBP targets above 160 mmHg were associated with further increased risk of both the composite and secondary outcomes.

**Conclusions:** Compared to the strategy of intensifying anti-hypertensive therapy when systolic blood pressure is greater than 140 mmHg, both higher and lower blood pressure targets were associated with increased cardiovascular morbidity and mortality.

**Implications for Policy, Delivery, or Practice:**
In patients with hypertension, both excessively high and low SBP targets were associated with increased cardiovascular events and death. A SBP target of 140 mm Hg may represent the best balance between the risks of overtreatment and undertreatment for hypertension.

CONSUMER CHOICE AND BEHAVIOR

A Randomized Controlled Trial of Implementation Strategies for PSA Screening Decision Support Interventions Comparing Men Turning 50 versus Men Over 50

Jared Adams, Health Services Research, Palo Alto Medical Foundation Research Institute, Palo Alto, CA; UCSF Philip R. Lee Institute for Health Policy Studies, San Francisco, CA; Dominick L Frosch, Gordon and Betty Moore Foundation, Palo Alto, CA; Department of Health Services Research, Palo Alto Medical Foundation Research Institute, Palo Alto, CA; Division of General Internal Medicine & Health Services Research, Department of Medicine, UCLA; Ming Tai-Seale, Health Services Research, Palo Alto Medical Foundation Research Institute, Palo Alto, CA.; Giwen Huang, Health Services Research, Palo Alto Medical Foundation Research Institute, Palo Alto, CA.; Mathew Nielsen, Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill; Department of Surgery, University of North Carolina at Chapel Hill; Michael Pignone, Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill; Department of Medicine, University of North Carolina at Chapel Hill; Carmen L. Lewis, Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill; Department of Medicine, University of North Carolina at Chapel Hill

Presenter: Jared Adams, M.D., Ph.D., Health Policy Fellow, Health Services Research, Palo Alto Medical Foundation Research Institute, Palo Alto, CA; UCSF Philip R. Lee Institute for Health Policy Studies, San Francisco, CA, impmsgs@netscape.net

Research Objective: Men turning 50 are faced with the choice to be screened for prostate cancer for the first time. We hypothesized that men turning 50 would be more likely to review a decision support intervention (DESI) about PSA screening than men over 50 and subsequently less likely to undergo screening.

Study Design: A random sample of men turning 50 and another cohort ages 50 to 75 with no screening in the past year from electronic medical records (EMR). We randomized patients into 4 arms: (1) mailed Informed Medical Decisions Foundation PSA-DESI, (2) invitation to a shared medical appointment (SMA) to watch and discuss the PSA-DESI, (3) both mailed DESI and invitation to a SMA (DVD+SMA), and (4) a control group. Four months after randomization, a survey was administered and EMR reviewed.

Population Studied: Men eligible for PSA prostate cancer screening at a large multispecialty group practice.

Principal Findings: A total of 811 (of 1448; 56%) men turning 50 and 958 (of 1578; 60.7%) men aged 51 to 75 (mean age 59±6) completed the questionnaire. Eighty percent of men over 50 had a prior PSA test. Contact with PCPs was similar in the four month follow up period (30% and 33%; p=.08). but men turning 50 were more likely to discuss PSA screening with their physicians (55.2% vs. 44.6%; p=.01); and were less likely to get a PSA test (9.9% vs. 19.3%; p<.0001). Overall DESI uptake was lower in men turning 50 (9.5% vs. 13.3%; p=.03). Methods of DESI implementation did not produce significant differences in PSA test rates (9.1% in arm 1, 6.5% in arm 2, 8.1% in arm 3, and 5.9% in the control arm; p=.65). In regression models, only prior PSA testing (OR 3.1, 95%CI 1.6—5.9) predicted likelihood of PSA testing.

Conclusions: In this large scale randomized controlled trial of real world PSA decision support effectiveness, PSA screening did not differ by implementation strategy. Men turning 50 were more likely to discuss PSA testing with their doctor, but less likely to choose to be screened. Higher PSA screening rates in men with a prior history of testing may represent resistance to change in cancer screening habits.

Implications for Policy, Delivery, or Practice: These findings highlight the importance of facilitating informed decision making at the onset of screening eligibility, or before cancer screening is considered for the first time.

The Impact of Retail Clinics on Total Outpatient Care

Scott Ashwood, RAND; Ateev Mehrotra, University of Pittsburgh and RAND; Martin Gaynor, Carnegie Mellon University; Amelia Haviland, Carnegie Mellon University; Claude M. Setodji, RAND

Presenter: Scott Ashwood, M.A., Ph.d. Candidate, Public Policy, RAND, ashwood@rand.org

Research Objective: Retail clinics are a new model for delivering outpatient care and have
been touted as a mechanism to decrease spending. Prior work has shown that two-thirds of visits to retail clinics are new visits rather than substitution for physician office and ED visits and therefore drive increases in acute care costs. However, this work could be criticized, because total utilization of outpatient care could still be lower for retail clinic users, because they might use the physician less frequently for chronic illness and preventive care. In this study we assess this question and look at the impact of retail clinics on utilization of all outpatient care.

**Study Design:** We used commercial claims and enrollment data covering 2005-2009 to compare patterns of utilization for retail clinic users and non-users in 22 markets around the United States. We used propensity score matching to identify a comparison cohort of enrollees that were similar to retail clinic users and used a differences-in-differences model structure to compare changes in levels of utilization in the year before and after a retail clinic visit. In addition to total outpatient utilization we compared levels by setting and by type. We estimated an average effect for the entire study population as well as for important sub-populations, like new health care users.

**Population Studied:** Our sample includes all enrollees who visit a retail clinic 2007-2009 in the 22 study cities (n=367,448) as well as a random sample of the remaining enrollees (n=1,010,910). We restrict our study population to enrollees aged <65 and who live within 20 miles of a retail clinic.

**Principal Findings:** We find that visiting a retail clinic is associated with an increase in the following year of 18.2% in total outpatient visits per person, an increase of 20.0% in preventive care visits, and an increase of 25.7% in simple acute care visits. We see the same impact for most of the sub-populations we examined.

**Conclusions:** In our population, retail clinic visits are associated with an increase in all types of utilization, including preventive care and chronic illness care. These effects are consistent across most of the sub-populations we examined.

**Implications for Policy, Delivery, or Practice:** Visiting retail clinics is associated with increases in acute care utilization and total outpatient utilization. The increase in preventive care may be a positive impact, but the results do not support the idea that retail clinics can decrease spending.

**From the Closest Observers of Patient Care: Consumer Understandings of Hospital Quality**

Naomi Bardach, University of California, San Francisco; Audrey Lyndon, PhD, University of California San Francisco; Renee Asteria-Penaloza, MPH, University of California San Francisco; L. Elizabeth Goldman, MD MCR, University of California San Francisco; R. Adams Dudley, MD MBA, University of California San Francisco

**Presenter:** Naomi Bardach, M.D., M.A.S., Assistant Professor, General Pediatrics, University of California, San Francisco, bardachn@peds.ucsf.edu

**Research Objective:** With the inclusion of patient experience measures in the Centers for Medicare and Medicaid value-based purchasing program, patient experiences have become a focus of national attention. In addition, recent work has shown that online hospital patient experience ratings are associated with patient outcomes including mortality and readmissions. Our objective was to analyze online hospital reviews to assess the extent to which they reflect nationally accepted conceptual frameworks for quality and delineate additional domains of quality that may explain the association with patient outcomes.

**Study Design:** Narrative reviews came from Yelp.com, the only publicly available website with multiple hospitals with multiple reviews. 100 comments, sorted by date, were sampled in February 2012 from online publicly available reviews on hospital quality, stratified by region according to proportion of the 2010-2011 census population in that region. We used thematic qualitative analysis, deductively coding the Institute of Medicine (IOM) quality domains and the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) domains, and inductively coding new themes. The review was the unit of analysis. We assessed the frequency of each IOM and HCAHPS domain and we described new themes qualitatively.

**Population Studied:** Narrative reviews from inpatients or friends or family members of inpatients were included (n=48). Reviews that were less than a full sentence and reviews from hospital employees were excluded. In order to code for the HCAHPS domains, reviews of
outpatient services or the emergency department were excluded.

**Principal Findings:** We found that the IOM domains most commonly noted in reviews were patient-centeredness (n= 45, 93.8%), effectiveness (54.2%), and timeliness (33.3%). Few reviews noted the HCAHPS domains of explanation of medications (14.6%) and discharge instructions (4.2%). Additional themes included: medical teamwork and coordination between providers; the out of pocket costs of care; poor experiences with billing departments; hospital reputation; and the interplay between a patient’s expectations and their experience of care.

**Conclusions:** Patients and friends and family members observing hospital medical care value some aspects of care known to be important, such as efficacy and timeliness of care. Reviewers also note additional elements that are potentially modifiable for the hospital, such as billing department communications, and potentially important to patient outcomes, such as care coordination.

**Implications for Policy, Delivery, or Practice:** Unstructured patient observations may be a valuable source of actionable feedback. It may be important to track whether consumer definitions of quality evolve over time with ACA implementation and the resulting cost and quality transparency.

**Funding Source(s):** NIH

**Regional Variations in Awareness of Quality Reports among People with Chronic Conditions**

Dennis Scanlon, Penn State University; Neeraj Bhandari, Penn State; Yunfeng Shi, Penn State University; Neeraj Bhandari, Penn State University

**Presenter:** Neeraj Bhandari, Phd Student, health policy and administration, Penn State, nwb5090@psu.edu

**Research Objective:** Recent years have seen the emergence of performance measurement and public reporting of quality of health care as a major reform strategy for improving health care. Very little empirical information on regional variation in awareness of comparative quality information (CQI) exists. The aim of this study is to examine regional variation in awareness of CQI for doctors, hospitals and health plans among the fourteen market sites that are part of the Aligning Forces for Quality (AF4Q) Project, a national level community-based multi-stakeholder health improvement collaborative. A further aim is to compare regional incidence of awareness with regional availability of CQI that has been publicly reported by state, local and national entities.

**Study Design:** We conducted a descriptive analysis of the data from two rounds of consumer survey of chronically ill consumers residing in one of the 14 AF4Q communities. We derived population weighted estimates of prevalence of awareness of CQI on doctors, hospitals and health plans by region and time period, along with estimates of change in awareness of CQI for individuals from across the two time periods, 2007-2008 and 2011-12. We calculated Pearson correlation coefficients between change in regional awareness and change in regional availability of CQI on doctors, hospitals and for selected chronic conditions.

**Population Studied:** Adults with one or more of five chronic conditions (diabetes, heart disease, hypertension, asthma, and depression) who reside in one of the 14 AF4Q communities.

**Principal Findings:** The percentage of overall population residing in the fourteen regional markets (all-site population) that was aware of any CQI was 45.6% in 2007-08 and 48.2% in 2011-12, yielding an increase in awareness of CQI of 2.6% over nearly four years. During the same time period, among the all-site population, awareness of CQI on doctors increased by 3.39% (12.7% in 2007-08 to 16.1% in 2011-12), of CQI on hospitals increased by 1.13% (25.3% in 2007-08 to 26.4% in 2011-12), and of CQI on health plans increased by 2.3% (27.2% in 2007-08 to 29.5% in 2011-12). We found a significant negative correlation between change in percentage of site population aware of a physician quality report and changes in availability of ambulatory patient experience report (-0.39) and publicly available physician quality report (-0.38). On the other hand, change in percentage of site population aware of any quality report was positively correlated with change in availability of quality reports with diabetes measures (0.42) but was not correlated with change in availability of reports with depression measures (-0.02).

**Conclusions:** Although there is some variability in regional awareness patterns for CQI across regions represented by AF4Q alliances, the increases in awareness of CQI among chronic disease patients from 2007-08 to 2011-12 have
been modest and lag behind relative availability of CQI.  

Implications for Policy, Delivery, or Practice:  
Our study provides some of the first empirical analyses on regional patterns and the change of awareness of CQI among a key target group for public reporting initiatives i.e. consumers with chronic conditions, over a period of time marked by intensifying national and regional public reporting efforts. Our findings suggest a need for more intensive focus on promoting awareness of CQI among consumers in order to fully realize health policy goals linked to public reporting.

Nonurgent Utilization of Emergency Room Services in California  
Brian Chen, University of South Carolina  

Presenter: Brian Chen, Assistant Professor, University of South Carolina, bchen@mailbox.sc.edu  

Research Objective: To evaluate the prevalence, socioeconomic, and behavioral determinants of utilization of emergency department services for non-urgent medical conditions in California, 2005-2011, with an emphasis on the geographical distances between the patients’ zip code of residence, the Emergency Department visited, and the closest Federally Qualified Health Centers for the underserved populations.  

Study Design: Retrospective secondary data analysis using ordinary least squares and probit models, using data from the California Office of Statewide Health Planning and Development on all emergency department visits, 2005-2011.  

Population Studied: All emergency room visits in California, 2005-2011  

Principal Findings: Almost 30% of all ED visits are classified as “non-urgent” according to the NYU ED algorithm. Even among patients eligible to receive care at Federally Qualified Health Centers (FQHCs), non-urgent ED utilization was frequent despite the geographical proximity of a FQHC.  

Conclusions: Nonurgent utilization of ED services is rampant, even when alternative and more cost-effective methods of care are available. This presents a significant waste of scarce health care resources.  

Implications for Policy, Delivery, or Practice:  
Better promotion of the availability of health care resources, as well as a triage and referral system among the most overcrowded emergency departments may be warranted.  

Funding Source(s): Other, University Intramural Grant  

Poster Session and Number: C, #964  

The Impact of High-Deductible Health Plans on Emergency Department Use and Subsequent Hospitalizations among Patients with and without Mental Illness  
Chia-hung Chou, University of Chicago; Christine Y. Lu, Harvard Medical School and Harvard Pilgrim Health Care Institute; Dennis Ross-Degnan, Harvard Medical School and Harvard Pilgrim Health Care Institute; Stephen B. Soumerai, Harvard Medical School and Harvard Pilgrim Health Care Institute; J. Frank Wharam, Harvard Medical School and Harvard Pilgrim Health Care Institute  

Presenter: Chia-hung Chou, Ph.D., Research Associate (Assistant Professor), Medicine, University of Chicago, chchou@uchicago.edu  

Research Objective: High-deductible health plans (HDHPs) have become increasingly popular in healthcare systems as a means to contain rising health care costs. Studies have shown that patients switching to HDHPs were less likely to go to the emergency department (ED) than those remaining in traditional plans (HMOs). The avoidance of needed care due to increased out-of-pocket costs can be particularly harmful for patients with mental illness. Our objective was to assess the effect of HDHP membership on ED visits and subsequent hospitalizations among patients with and without mental illness.  

Study Design: We analyzed Harvard Pilgrim Health Care administrative claims and membership data from 2001 to 2008. Using a pre-post with comparison group design and difference-in-difference models, we retrospectively evaluated the effect of HDHPs on ED visits and hospitalizations among patients age 18 to 64 with and without mental illness. ED visits were classified as low, indeterminate, or high severity. We examined changes in rates of ED visits and hospitalizations among members who experienced an employer-mandated switch to an HDHP relative to control group members who remained in HMOs. The index date in our pre-post analyses was the date on which a member was switched to a HDHP.  

Population Studied: The HDHP study group comprised members whose employers switched
them to an HDHP. The control group included members whose employers offered only traditional plans. Mental health patients were identified by specified ICD 9 codes and prescriptions records. The mental health and non-mental health cohorts were propensity-score-matched separately using caliper matching without replacement. On average, 3.2 concurrently enrolled control group members were matched to each HDHP member. The final study cohorts consisted of 12,497 HDHP members (including 2,747 members with mental illness), and 37,611 control group members (including 8,659 members with mental illness).

**Principal Findings:** The HDHP and control groups were closely balanced on observed characteristics, including age, gender, health status, employer size, and comorbidities. HDHP members with mental illness experienced relative declines in ED visits (-5%) and hospitalizations (-9%) compared to controls following transition to HDHPs, but these differences were not statistically significant. In contrast, ED visits and hospitalizations declined by 18% and 24% respectively among HDHP members without mental illness compared to controls (95% confidence interval -25% to -11%; and -35% to -11% respectively) after the first year of follow-up. The comparisons between HDHP members and controls, with or without mental illness, were similar across different levels of severity for ED visits.

**Conclusions:** Our preliminary analyses showed reductions in ED visits and hospitalizations among HDHP members, and the observed decreases were significant among patients without mental illness. Further analyses are underway to examine if HDHPs have negative impact on care-seeking behaviors among patients with mental illness compared to those without mental illness.

**Implications for Policy, Delivery, or Practice:** Previous cost-sharing literature suggests patients with mental illness are more at risk of forgoing needed care in the context of increased out-of-pocket costs. As HDHPs become widely popular due to their deemed potential in containing rising health care costs, rigorous studies are warranted to determine HDHPs’ intended and unintended impacts on various outcomes of different patient populations.

**Preferences for Family Involvement in Care by Consumers with Serious Mental Illness**

Amy Cohen, Greater Los Angeles VA Healthcare Center; Amy L. Drapalski, PhD, VA Capital Network Mental Illness, Research, Education and Clinical Center; Shirley M. Glynn, PhD, Greater Los Angeles VA Healthcare Center and UCLA; Deborah Medoff, PhD, VA Capital Network Mental Illness, Research, Education and Clinical Center and University of Maryland, Baltimore; Li Juan Fang, MS, VA Capital Network Mental Illness, Research, Education and Clinical Center and University of Maryland, Baltimore; Lisa Dixon, MD, MPH, New York State Psychiatric Institute, Columbia University College of Physicians and Surgeons, New York City

**Presenter:** Amy Cohen, Ph.D., Psychologist, Mental Illness Research, Education, and Clinical C, Greater Los Angeles VA Healthcare Center, ancohen@ucla.edu

**Research Objective:** Despite robust evidence of efficacy, family services for individuals diagnosed with serious mental illness are of limited availability and drastically underutilized. Underutilization may be due to a mismatch between consumer and family preferences and the services offered. This study is the first systematic report on preferences for family involvement by consumers with serious mental illness.

**Study Design:** These data come from a multi-site, randomized controlled trial of a shared-decision making intervention. 232 mental health consumers diagnosed with serious mental illness at three VA medical centers enrolled. Baseline interviews elicited demographics, treatment preferences regarding family involvement, and perceived benefits and barriers to involvement. Measures of symptom severity, family functioning, and chart diagnoses were collected.

**Population Studied:** Veterans with serious mental illness who had regular family contact but no family involvement in their mental health care were the population included.

**Principal Findings:** Consumers were, on average, 52 years old (SD=9), male, African American, and not currently married. The vast majority had a diagnosis of bipolar disorder or schizophrenia. Consumers had low levels of clinician-rated psychotic symptoms: PANSS positive subscale mean=13.3 (SD=5), PANSS negative subscale mean=12.9 (SD=5).
Consumers’ level of mental health recovery, as measured by the Mental Health Recovery Measure (MHRM), was consistent with the literature from several mental health consumer groups (mean=76.2, SD 18.3), indicating moderate levels of recovery. In terms of consumer preferences, 78% (171/219) wanted their family involved in their care and many desired involvement through several methods: family contact with the treatment team (71%), educational materials for the family (62%), family attendance at an educational or support group (56%); and family attendance at a treatment session (51%). Preference for family involvement was significantly predicted by perceived benefits (p<.01) after controlling for need for family services (family conflict, family-related quality of life, and symptom severity), enabling factors (family contact, family capacity), demographic variables (age, gender, race, living with family, and marital status), and perceived barriers (F=5.78, df=12, 149, p<.01). This model explained 32% of the variance in perceived preferences, which was significantly more variance explained than a model without demographic characteristics, benefits and barriers (F=7.92, df=7,149, p<.001). None of the measures of need, enabling factors, psychosocial factors, or the perceived barriers were significant individual predictors of preferences.

Conclusions: Consumers in this study wanted their family involved; many desired involvement via several methods. The degree to which a consumer expected benefits from family involvement in care predicted the degree of desired family involvement, whereas anticipating barriers did not.

Implications for Policy, Delivery, or Practice: Family services should be offered to all consumers annually. Since research indicates that family involvement has some of the most robust positive outcomes, it is imperative that clinicians be quite skilled in using motivational interviewing and collaborative decision making skills to help consumers understand the benefits of family services. Provider incentives to include families in services should be considered.

Health Practices, Beliefs and Values among the Uninsured
Norma Conner, University of Central Florida

Presenter: Norma Conner, Ph.D., R.N., Assistant Professor, College of Nursing, University of Central Florida, norma.conner@ucf.edu

Research Objective: To determine the predisposing population characteristics including demographics, health beliefs, self-care practices, locus of control, and values identified by uninsured adults, so healthcare providers can respond with appropriate interventions to reduce the disparities created by an uninsured status. Andersen's (1995) behavioral model of health services use was used as the framework for this study.

Study Design: This qualitative study consisted of a combination of focus groups and individual interviews. Informed consent measures were followed. Ninety minute focus group and sixty minute individual interviews, consisting of 10 open-ended questions in 3 categories, were conducted in a semi-structured format. Sessions were tape recorded, and transcribed verbatim. A demographic data sheet was also completed by each participant.

Population Studied: Participants were recruited from community based organizations such as worship sites in Central Florida. Participants meeting the study criteria of male and female, uninsured, 18 year of age and older but younger than 65 years of age, able to read and write in English were included in the study.

Principal Findings: Participants ranged in age from 19 to 69, and were heterogeneous in gender, marital status, employment and insurance eligibility. Main circumstances leading to an uninsured status included loss or change of employment, expense of coverage, self-employed status, and frustration over the Medicaid process. Beliefs, practices, and experiences related to an uninsured status include avoiding activities where injury is possible such as sports, borrowing money from family members to pay high cost to access private healthcare, information seeking among other uninsured individuals to obtain care, presenting false symptoms to access care, plans for emergency care or needed surgery that begin with presenting at the Emergency Department, and maintaining automobile insurance as required by law. Personal meaning attributed to having insurance included feeling
valued, and having choices and real autonomy in health care decision making. Most indicated an external locus of control related to whether or not they had insurance.

**Conclusions:** An individual’s uninsured status creates health behaviors such as telling untruths, and borrowing money to access health care. There exists an information network among the uninsured where they share information on getting health care. Lack of health insurance compromises values upheld in the US such as autonomy and self-determination when healthcare is beyond reach.

**Implications for Policy, Delivery, or Practice:** Health policy mandating insurance coverage is poorly understood. Health care providers are important to the education of the uninsured regarding responsibility to acquire health insurance coverage in connection with the Affordable Healthcare Act, health maintenance practices, how to recognize conditions requiring intervention, and accessing no/low cost healthcare services in the community. Health care providers can advocate for the uninsured to eradicate the need to lie to gain access to primary care and narrow the cost for service gap between the insured and the uninsured. Faith-community nurses are one resource providing important free services to help uninsured individuals manage their chronic conditions and link to other community resources.

**Implementing and Evaluating the Guide to Patient and Family Engagement: Improving Hospital Quality and Safety by Engaging Patients and Family Members in Their Care**

Kristin Carman, PhD, American Institutes for Research; Pamela Dardess, American Institutes for Research; Ushma Patel, MSPH, American Institutes for Research; Lauren Smeeding, American Institutes for Research; Callan Blough, American Institutes for Research; Margaret Savage, American Institutes for Research; Kirsten Firminger, PhD, American Institutes for Research; Marjorie Shofer, MBA, BSN, Agency for Healthcare Research and Quality

**Presenter:** Pamela Dardess, M.P.H., B.A., Senior Research Analyst, American Institutes for Research, pdardess@air.org

**Research Objective:** The Patient Protection and Affordable Care Act (ACA) highlights the role of consumers in improving health care and emphasizes the importance of patient engagement and patient experiences of care. The tangible importance of consumer engagement is realized in the Hospital Value-Based Purchasing Program, where hospitals face payment incentives that include patient experiences of care in the form of HCAHPS scores.

The purpose of this study was to implement and evaluate a Guide to Patient and Family Engagement in Hospital Safety and Quality that is intended to help hospitals develop effective partnerships with patients and families to drive improvements in engagement and quality. The Guide, funded by the Agency for Healthcare Research and Quality, and based on an evidence-based conceptual framework, includes four strategies that support patient engagement: Working with Patients and Families as Advisors: Helping hospitals work with patients and families as organization-level advisors. Communicating to Improve Quality: Improving communication between patients, families, and hospital staff from the point of admission. Nurse Bedside Shift Report: Supporting safe handoffs by involving patients and families in nurse change-of-shift report. IDEAL Discharge Planning: Engaging patients and families in the transition from hospital to home.

**Study Design:** In 2011, three hospitals began a 9-month implementation of the Guide. We conducted a pre-post evaluation to capture lessons learned, assess the Guide’s impact on the knowledge, attitudes, and behaviors of patients and staff; and investigate changes in hospital culture. Our mixed-method evaluation involved collecting qualitative (interviews with hospital staff, observation, focus groups with patients, and documentation collection), quantitative (staff and patient surveys), and extant data from hospitals (e.g., HCAHPS).

**Population Studied:** The Guide was implemented in three hospitals that varied in size, location, teaching status, and patient population: a 324-bed independent hospital in Annapolis, MD; a 200-bed community hospital in Chicago, IL; and a 72-bed rural hospital in Greenville, SC.

**Principal Findings:** Hospitals implemented the Guide with minimal technical assistance. Evaluation findings demonstrated positive outcomes associated with implementation. The staff survey demonstrated significant associations between Guide implementation and...
constructs related to Perceptions of Leadership (i.e., attitudes and behaviors of hospital leaders related to PFCC), Communications of Hospital Standards (i.e., communication of the importance of PFCC concepts), and General Practices of Care (i.e., behaviors related to integrating patients and families into care). During the implementation period, hospitals observed HCAHPS scores that trended upward, particularly in the communication, pain management, and discharge domains. Qualitative data showed that Guide strategies helped patients be more informed about their care and improved communication between patients and nurses.

Conclusions: The Guide provides evidence-based strategies that hospitals can implement to increase patient engagement and affect outcomes related to quality and satisfaction.

Implications for Policy, Delivery, or Practice: There is a growing view that consumers are a critical part of the solution to growing health care costs and lagging quality. With the inclusion of HCAHPS scores in the Hospital Value-Based Purchasing program, it’s critical to understand what organizations can do on a concrete level to promote engagement. This study addresses the dearth of on-the-ground evidence and outcomes about how to promote patient and family engagement.

Conveying Information to the Public About the Hazards of Hospital Care

Presenter: Rachel Dolin, M.A.Sc., Research Associate, L&M Policy Research, LLC, rdolin@lmpolicyresearch.com

Research Objective: Since 2002, the Centers for Medicare & Medicaid Services’ Compare websites have become the primary vehicle for reporting provider-specific quality information to the public, both to hold providers accountable for the care they deliver and to engage the public in efforts to improve quality. Legislative and administration initiatives are expanding the focus to include measures of safety, efficiency, and value. In the context of ongoing government-wide initiatives to promote safety, this study sought to explore consumers’ perceptions and understanding of information about medical errors, preventable deaths, injuries, complications, and infections in hospital settings, as it would be displayed on the Hospital Compare website.

Study Design: Using a qualitative research design, we consulted with subject matter and policy experts in public health, conducted a literature review on risk communication in health care decision making, and performed an environmental scan of related public reporting practices to develop draft narrative explanations, messaging, and displays of comparative hospital performance on patient safety indicators (PSIs), inpatient quality indicators (IQIs), hospital-acquired conditions (HACs), and healthcare-associated infections (HAIs), to be displayed on the Hospital Compare website. In field research carried out in 2009 (PSIs and IQIs) and 2011 (HAIs and HACs), we conducted a combination of one-on-one in-depth cognitive interviews and small group discussions with a convenience sample of consumers recruited from the community at five sites, to elicit their perceptions and interpretation of the displayed information. We also interviewed a small number of referring physicians at two of the sites. We identified common themes and variations in respondents’ interpretation, based on study team observations and analysis of written notes and recorded interview transcripts.

Population Studied: Patients and family caregivers of patients aged 40-70 (n=94), mixed by race, gender, education levels, and prior hospital experience; community-based primary care physicians (n=6) and surgeons (n=2).

Principal Findings: Patients and family caregivers, like referring physicians, understand that individual safety indicators reflect serious risks to patients’ health and safety. However, they do not necessarily agree with messaging that hospitals or healthcare providers should be held responsible for things gone wrong. Consumers have limited awareness of the prevalence or magnitude of medical errors, preventable deaths, injuries, complications, and infections; they commonly misinterpret displays of both individual and comparative performance rates, as reported, regardless of reporting format; and they are unsure how, if at all, the information should be used.

Conclusions: Technical measures of patient safety, as currently reported, do not accurately
or effectively convey information to the public about the hazards of hospital care.

**Implications for Policy, Delivery, or Practice:**
To engage consumers effectively in public dialogue around safety, communication strategies should be developed that raise public awareness about the problems, their magnitude, and their prevalence, supported by reporting formats that allow consumers to discern meaningful variations in hospital patient safety.

**Innovative Data Mining Predictive Models in Improving Chronic Disease Care: Identifying Patients in Cardiovascular Domains**

Emad ElSebakhi, MEDai Inc., an Elsevier Company; Anton Berisha, MEDai Inc., an Elsevier Company; Omnia H. Elhagrassy, Mansoura University

**Presenter:** Emad ElSebakhi, Ph.D., Senior Scientist, Health Science, MEDai Inc., an Elsevier Company, ai_cornell@yahoo.com

**Research Objective:** Cardiovascular disease (CVD) is the number one cause of death worldwide. It covers a wide array of disorders, including diseases of the cardiac muscle and of the vascular system supplying the heart, brain, and other vital organs. The objective of this research is to optimize data mining in the participant selection process for chronic care management programs (CCMPro). This motivation will be achieved by investigating the strengths and capabilities of the most recent cutting edge-innovative ensemble learning and functional networks intelligence modeling schemes on cardiovascular databases for estimating and identifying patients in cardiovascular domains.

**Study Design:** Recently, data mining offers a significant advantage over conventional statistical techniques which often requires the normality assumption. Predictive modeling techniques are used by disease management programs to risk-stratify members in order to optimize the utilization of available clinical resources. Normally, data mining predictive modeling assigned a risk score for each member to identify members with chronic conditions that are amenable to disease management interventions. These chronic conditions markers can be used to evaluate the prevalence of chronic conditions within a population. Members with multiple chronic conditions would have a marker for each condition, and then they will have significant healthcare needs and would benefit from the focus on the care offered by a disease management program.

**Population Studied:** The training algorithms and methodologies will be proposed with its utilization in the clinical databases taking into considerations the new healthcare reforms strategies with its affordable care act (ACA) for better quality treatment, while reducing cost. Based on three years of data from numerous lines of businesses (Commercial/Medicare/Medicaid), we estimate the risk for future adverse events, identify physician practice patterns, and predict quality of care outcomes (e.g., risk of future cardiac diseases, namely, CHF, CAD, MI…etc).

**Principal Findings:** Comparative studies will be carried out to compare the model performance using different quality measures (c statistic, sensitivity, specificity, positive predictive value, root mean-squared errors) and identified population size to assess the differences among different cut point selection approaches, while identifying those members (patients) with: (i) an opportunity for cost reductions and then a chance for ROI; (ii) who are more severe.

**Conclusions:** Comparative studies will be carried out to compare the model performance using different quality measures (c statistic, sensitivity, specificity, positive predictive value, root mean-squared errors) and identified population size to assess the differences among different cut point selection approaches, while identifying those members (patients) with: (i) an opportunity for cost reductions and then a chance for ROI; (ii) who are more severe. The available disease management programs from both providers and payers: (Screening, Planning, and Acting) strategies, physicians and nurses will be able to provide the proper care management and outreach program by utilizing the results with the evidence-based cut points that incorporate condition-specific variations in risk. In addition, by efficiently targeting and intervening with future high-cost members, health care costs can be reduced.

**Implications for Policy, Delivery, or Practice:**
By efficiently targeting and intervening with future high-cost members, health care costs can be reduced.

Competition in the Post-ACA Health Insurance Marketplace: How Health Insurance Exchanges Can Successfully Attract and Retain Consumers

Brandy Farrar, American Institutes for Research; Jill Yegian, American Institutes for Research; Coretta Mallory, American Institutes for Research; Harmoni Joie Noel, American Institutes for Research; Steven Garfinkel, American Institutes for Research

Presenter: Brandy Farrar, PhD, Researcher, Health Policy and Research, American Institutes for Research, bfarrar@air.org

Research Objective: The Patient Protection and Affordable Care Act §1311(c)(4) requires that Health Insurance Exchanges (HIEs) be in place and ready to offer coverage by January 1, 2014. While the legislative mandate requiring all individuals to have health insurance creates a ready-pool of potential Exchange enrollees out of the uninsured, this is not a captive audience. Exchanges will have to compete for business with insurance companies and brokers who fulfill similar functions. The biggest incentive to enrolling in an Exchange is that this the only way to receive the premium discounts and tax subsidies provided by the ACA. But is this enough of a value proposition to entice the millions of uninsured Americans to purchase their health insurance through Exchanges? The purpose of this study is to identify the key issues consumers will consider when deciding whether to purchase insurance through the Exchanges. These findings will inform Exchanges as they seek to become and remain competitive in the health insurance marketplace.

Study Design: Data for this study come from the formative research conducted as part of the development of the Health Insurance Exchange Enrollee Satisfaction Survey, a survey commissioned by the Centers for Medicare & Medicaid Services to inform consumer decision-making about purchasing health coverage. Four focus groups with 33 individuals were conducted to solicit consumers’ perspectives on health insurance, health care, and the impending HIEs. Focus group transcripts were systematically reviewed for emergent themes.

Population Studied: Each focus group targeted consumers with characteristics similar to potential Exchange enrollees: (1) uninsured, with chronic conditions; (2) uninsured, low-income; (3) uninsured, young and healthy; and (4) members of the Massachusetts Health Connector Commonwealth Care program.

Principal Findings: Participants identified three main issues that would influence their decision to enroll in a HIE: the administrating agency, the quality and affordability of plans, and the type of assistance provided. First, participants assumed that if HIEs were administered by the government, they would be overly bureaucratic and that if they were run by payors, financial interests would trump consumer needs. These assumptions resulted in a skepticism and distrust of HIEs that muted interest in enrolling. Second, participants will consider whether their out-of-pocket costs will “really” be manageable given their financial situations and if the plans will be accepted by good doctors (especially their own). If not, participants are prepared to pursue other options, including opting out of coverage all together (even in the face of penalties). Third, consumers will consider the method, quality, and degree of customization associated with assistance. Displeasure with any of these areas would frustrate participants, leading them to end the process.

Conclusions: The financial assistance offered by the Exchanges provides a clear advantage to other options consumers face to meeting the insurance mandate. However, these benefits alone will not be enough.

Implications for Policy, Delivery, or Practice: Exchanges also need to market themselves in ways that reduce skepticism and distrust, create true cost savings that make purchasing through an Exchange feasible and worth it, offer high quality QHPs, and provide high quality customer assistance in ways that meet the needs of multiple types of consumers.

Patient Activation by DTCA Influences Primary Care Physicians’ Prescriptions of Celebrex for Osteoarthritis

Michael Fischer, Brigham and Women’s Hospital/Brigham Medical School; Jeffrey N. Katz, Brigham and Women’s Hospital; Lisa D. Marceau, New England Research Institute; Felicia L Trachtenberg, New England Research Institute; Jing Yu, New England Research Institute; John B. McKinlay, New England Research Institute

Presenter: Michael Fischer, M.D., M.S., Associate Professor Of Medicine, Division of Pharmacoepidemiology and
Research Objective: Direct to consumer marketing of medications is intended to “activate” patients to request the advertised medication from their physicians. There is limited data on the extent to which physicians alter prescribing patterns in response to specific requests from activated patients.

Study Design: We performed a factorial experiment in which primary care physicians viewed clinically authentic videotapes of “patients” presenting with symptomatic knee osteoarthritis (OA). The “patients” were played by professional actors who differed by sex, race (white, Black, Hispanic) and SES (higher, lower). Each physician viewed one vignette of a patient with typical symptoms of knee OA lasting for several months. In one half of vignettes the patient was ‘activated’ and asked: “I’ve seen ads for Celebrex and it looks just like what I need…A woman I work with takes it and she said it really works for her…so, I really want to try that.” The non activated patients requested help with their pain but did not ask for any specific medications: “I just want something to make it better.” Activated and nonactivated vignettes were balanced on sex, race and SES. Physicians were balanced by sex and years of experience. After viewing the videotape, the physicians completed a questionnaire in which they indicated the treatment(s) they would likely prescribe. We examined the association between patient characteristics, particularly activated vs. non-activated, and the medications the physicians said they would prescribe (celecoxib, non-selective NSAIDs, other) using a multivariate ANOVA model.

Principal Findings: 53% of the PCPs presented with a vignette including an active request for celecoxib reported that they would prescribe celecoxib, as compared with 24% of physicians seeing the identical vignette without an active medication request (p<0.0001). Physicians receiving an active request for celecoxib were less likely to report that they would prescribe a non-selective NSAID (29%) than physicians whose simulated patients did not request celecoxib (42%; p=0.06). Most of the non-selective NSAIDs specified are available as generics. Further, physicians who received an active request for celecoxib prescribed either a COX-2 or a traditional NSAID for 82% of vignettes, compared to 66% of physicians who did not receive an active request (p=0.004). The associations between active request and physician prescribing patterns were not influenced by patient characteristics (gender, race, SES) or physician characteristics (gender, experience).

Conclusions: Physicians presented with an activated request for celecoxib by a patient with typical knee OA were more than twice as likely to prescribe celecoxib compared to physicians encountering a non-activated patient who provided the same clinical history and they were also considerably more likely to prescribe any NSAID (selective or non-selective).

Implications for Policy, Delivery, or Practice: Given the higher price, increased risk of cardiovascular toxicity and similar efficacy of celecoxib compared to non-selective NSAIDs, these findings suggest that some types of patient activation may increase health care costs and compromise appropriateness of prescribing.

Explaining the Growing Gap in Smoking by Education
Abigail Friedman, Harvard University; David Cutler, Harvard University

Presenter: Abigail Friedman, B.A., PhD Candidate, Harvard PhD Program in Health Policy, Harvard University, afriedm@fas.harvard.edu

Research Objective: From 1950-1987, the education gradient in smoking grew rapidly, yielding differential trends in life expectancy as well as education gaps in low birth weight and old age disability rates. We test three explanations for the growing gaps in smoking rates: differential response by education to cigarette prices, differential response to tobacco company advertising, and differential response to public health information. We use data on initiation and cessation as well as choice of less harmful (i.e., lower tar and nicotine) cigarettes to examine the impact of these variables.

Study Design: Retrospective cohort studies of smoking initiation and cessation apply logistic regression to a new dataset we compiled on annual cigarette advertising expenditure as well as retrospective smoking histories derived from the 1978-1980 and 1987 NHIS data. Brand choice analyses are cross-sectional and use
newly available data on cigarette brands smoked by respondents to the 1978-1980 NHIS, released by the NCHS in response to our request. Based on primary sources, we assign each brand to its late-1970s filtration category—unfiltered, low filtration, or high filtration—and use multinomial logistic regression to examine education differentials in cigarette choice.

Population Studied: More than 45,000 respondents to the 1979-1980 and 1987 National Health Interview Survey, all ages 25 to 64 at interview.

Principal Findings: For both initiation and cessation decisions, we find statistically significant education differentials in responses to cigarette advertising as well as the availability of information on brand-specific tar and nicotine levels. Additionally, more educated male smokers are relatively more likely to quit when cigarette taxes are higher. All of these differentials contribute to the observed smoking gradients.

Brand choice analyses find that more educated smokers choose lower risk (i.e., high filtration) cigarettes, even when analyses are conducted within cigarette parent brands (such that marketing is similar). Controlling for cigarette filtration group, more educated smokers also smoke fewer cigarettes per day. Among high filtration cigarette smokers, more educated individuals differentially favor parent brands exclusively devoted to hi-fi cigarettes over those including multiple filtration-types. While the former results point to a risk-reduction motivation, this latter finding suggests that the marketing of high filtration brands might also contribute to the observed differential.

Conclusions: Our findings point to an education differential in smoking responses to cigarette advertising, risk information, and (for male smokers) tax rates as key drivers of rapid growth in smoking’s education gradient during the mid-twentieth century, with brand choice analyses suggesting differential demand for risk-reduction and aspects of brand-marketing as likely drivers of this behavior.

Implications for Policy, Delivery, or Practice: While immediate policy implications are limited due to the time period under consideration, better understanding what drives these differential responses might suggest new approaches to shrinking smoking’s education gap. Future research should consider the extent to which marketing practices, personality traits, cognitive factors, and behavioral tendencies explain these patterns, as well as how they play out in an internet era.

Engagement in Health and Wellness: Behavioral Economics and Incentives

Teresa Gibson, Truven Health Analytics / Harvard Medical School; J Ross Maclean, MD, Bristol-Myers Squibb; Ginger Carls, PhD, Truven Health Analytics; Brian Moore, PhD, Truven Health Analytics; Emily Ehrlich, PhD, Truven Health Analytics; Victoria Fener, StickK.com; Jordan Goldberg, StickK.com; Colin Baigel, MD, Bristol-Myers Squibb

Presenter: Teresa Gibson, Ph.D.,M.A., Senior Director, Healthcare Research, Truven Health Analytics / Harvard Medical School, teresa.gibson@thomsonreuters.com

Research Objective: Many employers have extended the size and scope of their incentive-based wellness programs since the final ruling on wellness incentives under HIPAA was released in 2006. In January 2011, a large firm implemented an online commitment program integrating principles of behavioral economics in the incentive-structure for workplace health promotion. Each employee could make their own commitments to meet health goals within predefined categories. Employees then earned points that could be redeemed immediately online for gift cards and prizes with a total value of up to $300 per person. The objective of this study was to analyze engagement with an online employer wellness commitment program and evaluate whether these types of programs tend to attract mostly healthy individuals (e.g. primary prevention) or if users also include employees with chronic conditions or high prior spending (e.g. secondary prevention). This study provides one of the first views of real-world use of an incentive-based commitment program with significant financial rewards integrated with information on health status and health spending.

Study Design: This cross-sectional study compared demographic and health characteristics of users and nonusers and analyzed individual and aggregate measures of engagement as well as engagement patterns of employees by health status and health spending.
Population Studied: Detailed 2011 data from the commitment program was combined with information from administrative medical claims data for 2,147 continuously-enrolled employees of a large firm. Measures were created reflecting the level of involvement with the program: number of commitments, progress report submission rate, referee usage, number of supporters, number of journal entries, completion of a health risk appraisal, completion of a biometric screening, points earned, smoking cessation success, and pounds lost. We then used factor analysis to generate an engagement measure that aggregated the 10 individual engagement measures into a single, employee-level measure using factor loadings as weights. This single explained 38% of the total variation in employee engagement.

Principal Findings: Employees of all ages participated in and engaged in the program. Engagement declined with age. Engagement rates for men age 18-34 were 3.91 times the rate of those of men age 55-64 (p<0.01) and engagement rates for women age 18-34 were 2.90 times the rate of women age 55-64 (p<0.01). Employees with a significant chronic illness or high levels of medical spending in the previous year participated and engaged at rates similar to those without chronic illness or high spending (p>0.10).

Conclusions: Unlike traditional programs, an online incentive-based wellness program including self-defined health goals can be used to reach employees with chronic illness and high prior spending.

Implications for Policy, Delivery, or Practice: Health care reform amends qualifying wellness plan requirements as of 2014 and employers will be permitted to allow up to a 30% incentive for achieving a health goal (and up to 50% for certain tobacco related goals). While traditional wellness programs are likely to continue to be offered, participation-based incentive programs can be utilized not only for primary prevention but for secondary prevention and management by individuals with chronic illness and high spending.

How Physicians’ Presentation of Information about PCI to Patients with Stable Angina May Contribute to Their Belief that It Is a Life-Saving Intervention

Sarah Goff, Baystate Medical Center; Kathleen M. Mazor, EdD, University of Massachusetts Medical School and Meyers Primary Care Institute; Michael B. Rothberg, Cleveland Clinic Foundation

Presenter: Sarah Goff, M.D., Assistant Professor, Medicine, Baystate Medical Center, sgoff911@gmail.com

Research Objective: More than 600,000 percutaneous coronary interventions (PCI) are performed annually in the U.S. For patients with chronic stable angina, the benefit of PCI is limited to symptom reduction, yet many patients mistakenly believe that PCI will prevent myocardial infarction (MI) or death. We sought to illuminate how physicians’ presentations of PCI may contribute to patients’ misperceptions.

Study Design: Using the Verilogue Point-of-Practice Database (which includes visits with >600 physicians in 9 geographic regions throughout the U.S.), we searched outpatient/non-acute visit transcripts recorded between March 2008 and August 2012 for mention of PCI, cardiac catheterization, angiogram or stent placement. After we developed an a priori codebook, one team member performed qualitative content analysis on all the transcripts, adding codes iteratively until theoretical saturation was achieved. A second member read a subset of transcripts and recommended revisions to the codebook. Codes were then revised and sorted into pertinent themes.

Population Studied: Patient-cardiologist discussions about percutaneous coronary intervention.

Principal Findings: We analyzed 36 transcripts. Patients ranged in age from 44-88 years (median = 67) and 9 (23%) were women. “Rationale for recommending PCI” was as a major theme. The associated sub-theme, “Physician presentation of PCI benefit” illuminated how physicians’ presentations may contribute to patients’ misperceptions. Many physicians informed patients that catheterization was the “only way to know for sure” about their coronary artery disease, suggesting that catheterization would be preferable to uncertainty about the presence, extent and location of disease. The implication was that
once they “know for sure”, an intervention could improve the patient’s outcome; “That will show us for sure...then we can probably just [sic] go ahead...put in a stent...[and] have it taken care of”. Some physicians over-simplified the pathophysiology by using plumbing imagery “...sometimes we can also use a Roto-Rooter [to eliminate a blockage]”. They also stated that PCI would “fix” the problem; “the next step forward is a cardiac catheterization, with the intent of fixing a problem if there is a problem”. When patients questioned the need for PCI, some physicians overstated PCI benefits both implicitly and explicitly; “You sound good, you look good, but I want to keep it that way... I don’t want things to happen to you while you’re walking the steps or riding your bike,” and “I wouldn’t want you to have another heart attack.” Only one physician explicitly stated that symptom reduction was the only benefit of PCI for stable angina and that there would be no reduction in mortality or risk for MI. Although many physicians informed patients that they would need to take medication, few discussed maximizing medical management as an alternative to PCI. When discussions of alternatives to PCI did occur, it was generally only after a patient expressed hesitation about PCI.

**Conclusions:** In this study, some physicians presented information about PCI in a manner that may contribute to patients’ misperception of the benefit of PCI for stable angina.

**Implications for Policy, Delivery, or Practice:**
A larger quantitative study is required to understand how often physicians may misrepresent the benefits of PCI and how changes in presentation may affect patient decision-making.

A Randomized Controlled Trial to Improve Low-Income Pregnant Women’s Access to Pediatric Quality of Care Data: Rationale and Study Design for “IDEAS for a Healthy Baby”

Sarah Goff, Baystate Medical Center; Katherine White, Baystate Medical Center; Penelope S. Pekow, Baystate Medical Center; Kathleen M. Mazor, University of Massachusetts Medical School; Peter K. Lindenauer, Baystate Medical Center

**Presenter:** Sarah Goff, M.D., Assistant Professor, Pediatrics, Baystate Medical Center, sgoff911@gmail.com

**Research Objective:** Efforts to increase transparency regarding health care quality and safety are partially guided by the belief that making quality performance data publicly available will enable patients to make more informed choices. Although the amount of data reported on websites and through other channels has increased, use by consumers remains limited and largely restricted to white, college educated and middle-aged consumers. Barriers to using these data include failure to recognize that quality varies, that the data are publicly reported, and that the data may be difficult to understand. Populations with low health literacy and numeracy are disproportionately affected by these barriers.

The objectives of the study are to: 1) test the efficacy of an office-based patient navigator to assist low income pregnant women in using publicly reported data to select a pediatric care provider; 2) assess the efficacy of the intervention in subgroups defined by parity, race/ethnicity, and health literacy; 3) evaluate the importance of publicly reported quality data compared to other factors when selecting a pediatric provider; and 4) assess the intervention’s impact on self-management of health care.

**Study Design:** Women will be recruited between 20-34 weeks of gestation. Women in the intervention arm will receive an informational pamphlet about health care quality plus two 20 minute sessions with a trained patient navigator who will help participants to use and interpret information about the quality of care provided at local pediatric practices on the Massachusetts Health Quality Partners website. Women in the control group will only receive the informational pamphlet. A survey designed for this study will be administered to all participants at baseline and post-intervention to assess outcomes of interest. Health literacy, numeracy and level of activation for self-management of health care will be assessed as potential mediators of intervention effectiveness.

**Population Studied:** English speaking women ages 16-50 attending a prenatal clinic that serves primarily a low income population at a large urban medical center will be enrolled in the study.

**Principal Findings:** The primary study outcome will be the average performance on clinical
quality measures and patient experience scores for the practices selected in the intervention versus control groups. Secondary outcomes will include analyses of efficacy among groups of women defined by parity and an assessment of the relative importance of factors women considered when choosing a pediatric care provider.

**Conclusions:** As health care quality data become increasingly available in publicly reported formats, there is a risk that barriers to accessing and understanding these data may increase health disparities. This study tests the theory that helping pregnant women with low health literacy and numeracy overcome these barriers will increase the consideration of performance on quality measures when choosing a pediatrician.

**Implications for Policy, Delivery, or Practice:** Use of support personnel such as patient navigators may increase the importance of performance on quality measures when choosing a pediatrician.

**WIC Policy Changes and Healthy Eating**

Tami Gurley-Calvez, University of Kansas Medical Center; Kandice Kapinos, U.S. Census Bureau

**Presenter:** Tami Gurley-Calvez, Ph.D., Assistant Professor, Department of Health Policy and Management, University of Kansas Medical Center, tgurley-calvez@kumc.edu

**Research Objective:** To investigate the impact of recent changes to the US Department of Agriculture (USDA) Food and Nutrition Service (FNS) food packages provided through the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) servicing low-income and nutritionally-at risk pregnant and postpartum women, infants and children. In particular, the FNS issued an interim rule in 2007 to modify the WIC food packages to improve dietary intake among participants while maintaining cost neutrality. States had to implement this rule by no later than October 2010. Not only were the food packages changed to include vouchers for fruits and vegetables for WIC participants, but the minimum stock requirements of WIC vendors were changed. While states were allowed to impose more stringent requirements, the FNS required at a minimum that WIC vendors stock at least two varieties of fruits and two varieties of vegetables. This study investigates whether a) provision of the vouchers resulted in a greater fruit and vegetable consumption among WIC participants and b) whether the effects were larger for individuals in states with more stringent vendor stocking requirements.

**Study Design:** We utilized a difference-in-difference (DD) strategy to investigate the effect of the interim rule on WIC participants’ consumption of fruits and vegetables using Behavioral Risk Factor Surveillance System (BRFSS) data from 2005-2011. Our identification strategy relies on cross-state differences in both provisions of the produce vouchers and WIC vendor policies to answer the question of whether increased access to healthier foods, namely greater fruits and vegetables, resulted in healthier diets among adults. Mechanically, our DD models regress daily fruit or vegetable intake on year indicator variables interacted with an indicator variable for whether the state imposed stringent stocking requirements and include a rich set of sociodemographic and health controls and state fixed effects. We also conduct falsification exercises to examine whether the new food packages decreased consumption of fruit juice, for which benefits were not changed.

**Population Studied:** We first restrict our sample to low-income pregnant females, but also consider other samples, including low income families with children.

**Principal Findings:** Our preliminary findings suggest that the voucher increased fruit and vegetable consumption among low-income pregnant females. However, we find no evidence that this effect was stronger in states with more stringent vendor stocking requirements.

**Conclusions:** Our work suggests that providing a cash voucher to WIC participants to purchase more fruits and vegetables increases fruit and vegetable consumption among WIC participants. While we found no evidence that changes to vendor stocking requirements yielded changes in consumption, more work is needed to investigate this.

**Implications for Policy, Delivery, or Practice:** This work has implications for future policy interventions aimed at increasing healthful eating. In particular, our work suggests that subsidizing healthier foods may encourage individuals to eat more healthful foods.

Factors Related to Attrition from VA Healthcare Use: Findings from the National Survey of Women Veterans

Presenter: Alison Hamilton, Ph.D., M.P.H., Research Health Scientist, Desert Pacific MIRECC, VA Greater Los Angeles, alison.hamilton@va.gov

Research Objective: To compare individual characteristics and perceptions about VA care between women Veterans who discontinued VA use (“attriters”) and women Veterans who continued VA use (“non-attriters”), and to compare recent versus remote attriters.

Study Design: Cross-sectional, population-based 2008-09 national telephone survey.

Population Studied: 626 attriters and 2,065 non-attriters who responded to the National Survey of Women Veterans.

Principal Findings: Fifty-four percent of the weighted VA ever user population reported that they no longer use VA. Forty-five percent of attrition was within the past ten years. Attriters had better overall health (p=0.007), higher income (p<0.001), and were more likely to have health insurance (p<0.001) compared with non-attriters. Attriters had less positive perceptions of VA than non-attriters, with attriters having lower ratings of VA quality and of gender-specific features of VA care (p<0.001). Women Veterans who discontinued VA use since 2001 did not differ from those with more remote VA use on most measures of VA perceptions. Overall, among attriters, distance to VA sites of care and having alternate insurance coverage were the most common reasons for discontinuing VA use.

Conclusions: We found high VA attrition despite recent advances in VA care for women Veterans. Women’s attrition from VA could reduce the critical mass of women Veterans in VA and affect current systemwide efforts to provide high-quality care for women Veterans. An understanding of reasons for attrition can inform organizational efforts to re-engage women who have attrited, to retain current users, and potentially to attract new VA patients.

Implications for Policy, Delivery, or Practice: Access to care is a VA priority. Since attrition is the flip side of access, preventing VA attrition is aligned with key VA priorities. In an era of increased consumer healthcare choice, the VA, like other healthcare institutions, needs to remain a provider of choice. An understanding of reasons for attrition can inform efforts to re-engage patients who have attrited, to retain current users, and even, potentially, to attract new VA patients. At the patient level, increased continuity of care through re-engagement or sustained, continuous engagement in care could promote early intervention to avert or reduce late-life diseases and their concomitant adverse effects on healthcare costs and quality of life.

Designing a Cost Comparison Tool for Cancer Patients: “The more people know ahead of time, the better”

Nora Henrikson, Group Health Cooperative; Leah Tuzzio, Group Health Research Institute; James Ralston, Group Health Research Institute; Diana SM Buist, Group Health Research Institute

Presenter: Nora Henrikson, Ph.D., M.P.H., Research Associate II, Group Health Research Institute, Group Health Cooperative, henrikson.n@ghc.org

Research Objective: Increasing healthcare costs are shifting to patients. Mounting evidence suggests people receiving chemotherapy want to know their out-of-pocket costs at the time of treatment selection and that cost may factor into treatment choice. We conducted this study to elicit user feedback on the utility and design of a prototype of a “treatment cost calculator”.

Study Design: We conducted a design evaluation of two paper prototypes based on a prior needs assessment. Our prototypes included prices for alternative chemotherapy regimens for colorectal cancer (Capox and Folfox-6) and a statement of their similar effectiveness and different costs, side effects, and number of infusion cycles. Costs for medication, infusion, labs, and supportive medications were included, as well as total cost and hypothetical patient out-of-pocket expense for the episode of care. The two prototypes differed by level of cost detail provided.

Participants were observed and interviewed while using the prototypes under simulated conditions. We used a modified think-aloud
design protocol to elicit participants’ perspectives about the prototype’s strengths, weaknesses and potential usefulness. Transcripts of the audio recordings were open-coded by two researchers to identify salient themes.

**Population Studied:** Twelve people receiving chemotherapy for cancer in 2012 at a nonprofit, member-governed integrated healthcare system. Two thirds of participants were female, median age 68 (42-77), two (17%) were participants in high-deductible health plans; 10/12 (83%) were Medicare beneficiaries. Half of participants had stage II cancer; half were stage III. Most common cancer types were breast (33%), and colorectal cancer (17%).

**Principal Findings:** Of 100 mailed invitation letters, we completed recruitment with the first 32 people we contacted. Twelve people (38%) declined, we were unable to reach eight (25%), and 12 (38%) consented and were interviewed. Most participants (10/12, 83%) found the prototype useful for selecting treatment or expense planning in the clinic setting. Participants appreciated seeing both total and patient-specific costs but preferred accurate price quotes over estimates or ranges. The majority said the tool would be most appropriate and useful during treatment planning rather that at the time of diagnosis. Just over half named a preference for using the tool in collaboration with either a doctor or nurse. Participants suggested a range of additional features. No one suggested deletions. Two participants contrasted sharply with others by objecting to the costs of cancer treatment being discussed in the clinical setting.

**Conclusions:** Our results suggest that clinic-based cost calculators are acceptable and useful to a meaningful portion of oncology patients. The preference of a minority of patients not to discuss costs in the clinic setting and the range of requests for specific features suggests that a personalized approach to cost comparison at the treatment planning stage is warranted.

**Implications for Policy, Delivery, or Practice:**
Cost comparison tools can provide a needed service of improved price transparency at the point of care and could improve clinical practice and patient-centered care.

**Assessing U.S. Household Purchase Dynamics for Dietary Fiber**

Miguel Henry-Osorio, Virginia Commonwealth University; Diansheng Dong, ERS

**Presenter:** Miguel Henry-Osorio, Ph.D., Instructor, Healthcare Policy and Research, Virginia Commonwealth University, mehenryosori@vcu.edu

**Research Objective:** Provide a first attempt at examining household purchase dynamics for dietary fiber. We investigate what drives consumers’ demand for dietary fiber in a dynamic choice and household level context, accounting for temporal correlations between current and previous purchases and controlling for left-censoring of observations across households and over time. Our goal is to better understand the dynamics of U.S. household purchasing decisions regarding fiber and perhaps explain why consumption remains at under half the recommended levels. This research may provide new insights that ultimately improve interventions or educational policies to enhance consumer demand for dietary fiber.

**Study Design:** For this study, we create a unique dataset by merging the 2009 Nielsen Homescan panel data and the 2005-2011 Gladson databases using heuristic algorithms and multiple sequential imputations based on product information (e.g., the Universal Product Code). The fiber household demand is modeled as a function of household demographic and socio-economic variables (household size, household income, age of the female head, education of the female head, employment of the female head, household participation in the WIC program, household type, Hispanic ethnicity, being African American, age and presence of children at the household, summer, fall, winter, east, central, and west), a price variable (the dollars per gram of fiber purchased), and a lagged-purchase variable of first order.

**Population Studied:** The Homescan Core panel data offer national coverage (excluding Alaska, Hawaii, and all off-shore U.S. territories), and consist of a panel of U.S. households. The Gladson nutrient database set provides information for an extensive group of packaged products sold in the U.S. on nutritional and front-of-package claims from industry leaders. Our final household population is of almost 47000 households (over 20 million observations).
Principal Findings: Household purchase decisions are characterized by significant unobserved heterogeneity, statistically significant positive serial correlation, and negative and significant state dependence. We also find that covariates that are not integral determinants of fiber intake are household participation in the WIC program, the age and presence of children between 13 and 17, not being Hispanic, and employment of the female head. The education level of the female head has a negative impact on fiber purchases, whereas coupons have the reverse effect. 

Conclusions: Habit persistence effects show that lagged purchases have a strong effect on current household decisions so that households purchasing previously would buy less fiber at time t. Regarding dynamic effects, elasticities of current fiber purchases vary depending on whether a previous fiber purchase occurred or not. In general, the demand for fiber is inelastic, becoming more elastic when it is conditioned on a non-purchase occasion at time period t-1. Household’s purchase timing becomes shorter when conditioning the probability of purchasing on a non-purchase occasion at time t-1 relative to the case in which the purchase probability is conditioned to a purchase occasion at time t-1.

Implications for Policy, Delivery, or Practice: Revisions to the WIC food packages, implemented in 2009, included the addition of whole grain bread (or brown rice or whole grain tortillas), the requirement that half of all breakfast cereals allowed by the state be whole grain, and the provision of cash vouchers for the purchase of fruits and vegetables. An avenue of future research would be to expand the current sample to 2010-11 Homescan datasets to determine whether show if the participation in new the WIC program becomes an integral determinant of fiber choices.

Public Quality Reporting - Do Consumers Know and Care?

Marco Huesch, University of Southern California Price School of; Aram Galstyan, USC; Elizabeth Currid-Halkett, USC; Jason Doctor, USC

Presenter: Marco Huesch, Ph.D., Assistant Professor Of Public Policy, Leonard D. Schaeffer Center for Health Policy and, University of Southern California Price School of, huesch@usc.edu

Research Objective: Public reports seek to inform consumers of important healthcare quality and affordability attributes, and may inform decision-making if consumers are aware of, and can rely and act on such information. We tested these three conditions in the ‘highly shoppable’ condition of maternity care.

Study Design: We used a media access platform with sentiment analysis to investigate blog, forum, social media and traditional media ‘share of voice’ for major public reports of hospital quality in California in 2012. For maternity care in Los Angeles, we examined inter-item reliability of the major public reports, the reported variation in 10 maternity care quality, experience and affordability metrics, and the availability of alternative hospitals for each metric within 10 mile radius choice sets of all 55 maternity hospitals.

Principal Findings: Irrespective of social, online or traditional media type, the three commercial suppliers (Healthgrades, Thomson Reuters Best Hospitals, and US News & World Report Top Hospitals) of hospital quality information dominated consumer awareness. The federal government’s HospitalCompare lookup tool was a distant 4th in mentions across all platforms, but in turn overwhelmingly dominated the state-level OSHPD and the non-profit CalHospitalCompare reports which were effectively absent from publicly disclosed social media or blog conversations. Commercial reports had higher sentiment scores than state, federal or non-profit reports. Inter-item reliability was poor: Cronbach’s alpha did not suggest high consistency of measurement across the reports. Within each report, factor analyses were not interpretable except for Healthgrades and HospitalCompare. These suggested that three separate latent constructs appeared to be recoverable: clinical quality, proneness to intervention (e.g. cesarean section), and subjective patient satisfaction. Variation in objective and subjective reported quality and experience metrics was high. Except for the generally low variability across hospitals in HospitalCompare’s patient experience results (CoV 10%), there was generally substantial variation across hospitals in each metric. This was particularly so for utilization metrics such as VBAC (107%), episiotomy rate (73%), and breastfeeding rates (50%). Alternatives were generally available in each choice set: averaged across the 55 hospitals, consumers had

Principal Findings: Irrespective of social, online or traditional media type, the three commercial suppliers (Healthgrades, Thomson Reuters Best Hospitals, and US News & World Report Top Hospitals) of hospital quality information dominated consumer awareness. The federal government’s HospitalCompare lookup tool was a distant 4th in mentions across all platforms, but in turn overwhelmingly dominated the state-level OSHPD and the non-profit CalHospitalCompare reports which were effectively absent from publicly disclosed social media or blog conversations. Commercial reports had higher sentiment scores than state, federal or non-profit reports. Inter-item reliability was poor: Cronbach’s alpha did not suggest high consistency of measurement across the reports. Within each report, factor analyses were not interpretable except for Healthgrades and HospitalCompare. These suggested that three separate latent constructs appeared to be recoverable: clinical quality, proneness to intervention (e.g. cesarean section), and subjective patient satisfaction. Variation in objective and subjective reported quality and experience metrics was high. Except for the generally low variability across hospitals in HospitalCompare’s patient experience results (CoV 10%), there was generally substantial variation across hospitals in each metric. This was particularly so for utilization metrics such as VBAC (107%), episiotomy rate (73%), and breastfeeding rates (50%). Alternatives were generally available in each choice set: averaged across the 55 hospitals, consumers had
substantial choices based on their hypothesized preferred metric within a choice set comprising all hospitals within a 10 mile radius of any particular hospital.

**Conclusions:** Consumers are more aware of and more positively disposed towards commercial hospital quality reports. Despite individual deficiencies and omissions, in aggregate the reports provided sufficient, usable information to consumers regardless of preferences.

**Implications for Policy, Delivery, or Practice:** Public stakeholders whose objectives are enhancement of quality, greater transparency and more empowered consumers through better quality reporting can profitably learn from the private sector. Their approaches to the coverage of providers, the content and reliability of the reported metrics, the validity of underlying constructs, and the achievement of market ‘share of voice’ and consumer ‘share of mind’ are all potentially valuable.

**Online Privacy and the Top 20 Health Sites**

Marco Huesch, University of Southern California Price School of

**Presenter:** Marco Huesch, Ph.D., Assistant Professor Of Public Policy, Leonard D. Schaeffer Center for Health Policy and, University of Southern California Price School of, huesch@usc.edu

**Research Objective:** Patients use the internet to access health-related information. In turn, web sites and their affiliated 3rd parties gather personal information from users. The resulting risk to privacy is increasingly well-known in the media, and computer science literature. Despite existing guidelines for healthcare online privacy, this problem remains poorly understood within the healthcare field. Therefore we used internet tools to understand the extent of this problem within popular health-related news and information websites.

**Study Design:** We used proprietary tools used to detect but not block the activity of more than 1,300 potential 3rd party entities including advertisers, data collectors, data aggregators and social networks. These place and use cookies, scripts, tags, and iframes to deliver advertising, monitor traffic for analytics, or serve page functionality. To track online behavior, tracking entities (e.g. tynt) directly insert beacons, conversion pixels, and cookies or place social buttons on the webpage to potentially gather information on user’s prior, current and subsequent online activity. A web proxy tool was used to monitor actual tracking communication between 3rd party elements on the test computer and the web while browsing. Within each site we browsed 10 pages randomly and searched for ‘depression’, ‘herpes’ and ‘cancer’.

**Population Studied:** A convenience sample of 20 high volume health category websites

**Principal Findings:** All 20 sites had at least one 3rd party element. The majority of these elements had non-tracking functions. However, 13 of the 20 websites had tracker elements. Physician-oriented sites had none, except for MdLinx.com. Commercial and mass media sites had more, and were more likely to allow social button tracking. Zip codes and home domain name were leaked to advertising delivery sites, and by one popular consumer health site to a tracker element scorecardresearch. Our computer’s IP address was leaked by two sites to tracker sites, and by one journal to a non-tracker site. Searches for sensitive terms such as “herpes” very often leaked to 3rd parties including tracking sites. Sensitive search terms were not leaked to 3rd party tracker elements on government sites, nor on 4 of 5 physician-oriented websites. Enabling proprietary privacy protection tools did not dramatically affect functionality of the websites.

**Conclusions:** Healthcare privacy concerns traditionally revolve around loss or theft of patient information from provider health records or the infrequent misuse of such information by providers. Yet much health-related information is not stored in electronic health records nor yet fully known by providers. Individuals possess information about their own symptoms, signs, disease burden, treatment and increasingly often search for related information online. To protect online user privacy, web sites generally restrict themselves and their 3rd party affiliates to aggregating user data and not allowing directly identifiable data to be generated or used. Nevertheless, the common installation and use of 3rd party tracker elements found in this study on popular websites is worrisome.

**Implications for Policy, Delivery, or Practice:** Patients and physicians concerned about online privacy may therefore obtain much of the benefit, and run far fewer risks, by using commonly available privacy tools when searching and browsing online.
How Effective is Health Coaching in Improving Health Outcomes and Reducing Health Services Utilization and Costs?

Yvonne Jonk, University of Minnesota Rural Health Research Center; Karen Lawson, MD, ABIHM, University of Minnesota Center for Spirituality and Healing; Heidi O’Connor, MS, University of Minnesota Rural Health Research Center; Kirsten Riise, PhD, Medica Research Institute; David Eisenberg, MD, Harvard Medical School; Bryan Dowd, PhD, University of Minnesota, Division of Health Policy and Management; Mary Jo Kreitzer, PhD, RN, FAAN, University of Minnesota Center for Spirituality and Healing

Research Objective: To evaluate the effectiveness of health coaching in improving health outcomes and reducing health services utilization and costs.

Study Design: High risk health plan enrollees were invited to participate in a health coaching intervention designed to improve participants’ health and wellbeing, motivate behavior change, increase motivation and self-efficacy, and manage health conditions. Health coaching participants chose to participate in either an active or self-directed track. Active participants voluntarily filled out a health inventory assessing their lifestyle, health, stress levels, quality of life, readiness to make lifestyle and behavior changes, and patient activation levels at baseline and upon completion of the program. Primary data were collected from January 2009 to December 2010.

Health coaching participants (i.e. the experimental group) were matched using propensity scores to a group of health plan members who didn’t participate in health coaching (i.e. the controls) and who were otherwise eligible to participate. The likelihood of participating in health coaching was estimated via logistic regression. Independent variables included the demographic, health plan, and health characteristics of the health plan members. Administrative claims data were used to analyze differences in health services utilization and costs between the experimental and control groups from the six months prior to and six months after participation in health coaching, i.e. June 2008 to June 2011. Matched controls were assigned pseudo-enrollment dates mimicking the experimental group’s distribution of the pre and post periods. A fixed effects difference in differences model was used to address the impact of health coaching on the experimental group’s use of health services and expenditures relative to the controls, controlling for sectoral trends.

Population Studied: Study participants were members of a health insurance plan that offered a telephonic health coaching program to assist in managing their health and healthcare needs.

Principal Findings: Of the 6,940 active participants, 1,082 completed pre and post health inventories, and 570 completed pre and post Patient Activation Measures (PAM). While less than 7% of potential candidates actively participated in health coaching, approximately half of those actively participating met at least one identified goal. On average, participants attended eight telephonic coaching sessions over a period of six months. Participants realized a 12% reduction in high stress levels, an 18% improvement in healthy eating, a 21% improvement in exercise levels, and a 12-15% increase in the percent reporting good physical and emotional health. Individuals realized an average of 8-9 point increase in Patient Activation scores with 60% reporting a clinically significant improvement of 5 points or more. Relative to controls, health coaching participants realized a significant reduction in outpatient and emergency room utilization and costs.

Conclusions: This study finds evidence of improvements in health and behavior outcomes and reduced health care expenditures following health coaching. Particular high risk subpopulations such as patients with diabetes and cardiovascular disease may warrant further study. While still in its initial stages of development, this program has the potential to expand its outreach and enrollment efforts.

Implications for Policy, Delivery, or Practice: Encouraging high risk enrollees to participate in health coaching appears to be a cost effective approach to improving population health while reducing outpatient and emergency room utilization and costs. Larger, more definitive studies are needed.

Out-of-Pocket Expenses and Treatment Choice for Men with Prostate Cancer

Olivia Jung, Harvard Business School; Thomas Guzzo, Division of Urology, Department of Surgery, Abramson Cancer Center, Perelman School of Medicine; David Lee, Division of Urology, Department of Surgery, Abramson Cancer Center, Perelman School of Medicine; Michael Mehler, Department of Radiation Oncology, Perelman School of Medicine; John Christodoulou, Department of Radiation Oncology, Abramson Cancer Center, Perelman School of Medicine; Curtland Deville, Department of Radiation Oncology, Abramson Cancer Center, Perelman School of Medicine; Genevieve Hollis, Department of Radiation Oncology, School of Nursing, University of Pennsylvania; Anand Shah, Department of Radiation Oncology, Columbia University Medical Center

Presenter: Olivia Jung, B.A., B.S., Doctoral Student, Health Policy Management, Harvard Business School, ojung@hbs.edu

Research Objective: To describe the knowledge of, and attitudes toward, out-of-pocket expenses (OOPE) associated with prostate cancer treatment.

Study Design: We undertook a qualitative research study for which we recruited patients with clinically localized prostate cancer. Patients answered a series of open-ended questions during a semi-structured interview and completed a questionnaire about the physician’s role in discussing OOPE, the burden of OOPE, the effect of OOPE on treatment decisions, and previous knowledge of OOPE.

Population Studied: We recruited patients with clinically localized prostate cancer who had been treated within the previous 6-18 months with surgery or external beam radiotherapy. We excluded patients who had received androgen deprivation therapy, did not speak English, or were cognitively impaired. A total of 41 (26 white and 15 black) eligible patients were enrolled from the urology and radiation oncology practices of the University of Pennsylvania.

Principal Findings: Qualitative assessment revealed 5 major themes: (a) “my insurance takes care of it”; (b) “health is more important than cost”; (c) “I did not look into it”; (d) “I cannot afford it but would have chosen the same treatment”; and (e) “It is not my doctor’s business.” Only 2 patients stated they knew “a lot” about the likely OOPE for different prostate cancer treatments before choosing their treatment.

Conclusions: Few patients with prostate cancer had knowledge of OOPE before making treatment choices in this single-institution study.

Implications for Policy, Delivery, or Practice: Despite recent calls for greater transparency in cost sharing for cancer treatment, the vast majority of patients reported having little knowledge of OOPE before making cancer treatment decisions. To begin to address the profound knowledge gap around OOPE, researchers could explore the use of a simple screening question about OOPE at initial consultations for cancer care. Moreover, communication models should be evaluated to reduce patients’ potential reticence to discuss treatment costs. The success of future efforts aimed at the laudable goal of participatory decision-making will require researchers to design and test methods to optimally frame these discussions and to train physicians and other healthcare team members on the best practices to achieve cost transparency.

The Time Trends and the Determinants of Adult Obesity Measured by a Fatness-Based Index

Minchul Kim, University of California, Davis

Presenter: Minchul Kim, Ph.D., Postdoctoral Scholar, Department of Public Health Sciences, University of California, Davis, mkim1971@gmail.com

Research Objective: A rapid and sustained rise in the obesity rate during the past three decades has stimulated a considerable amount of literature. The literature mainly defined obesity by a body mass index (BMI, weight in kilograms divided by height in meters squared). However, this measure has been criticized because it fails to distinguish body fat from lean body mass. My objectives are to (1) measure the prevalence of obesity defined by the fatness-based percent body fat (PBF, the ratio of body fat to total weight multiplied by 100) over time, and to (2) explore policy options to reduce the PBF-based obesity.

Study Design: I developed the PBF algorithm equation using the variables (such as weight, height and age by gender and race) from the
Principal Findings: The average PBF-defined obesity rate is 62% (22% in 1984 and 79% in 2009), being much greater than 21% (10% in 1984 and 34% in 2009) of the BMI-defined. On average, the former increased annually by 1% compared to 0.9% of the latter. Racial and gender differences are contradictory between two obesity indexes (outcome variables). The White American and the Female are less obese in the BMI-defined obesity, but more obese in the PBF-defined obesity than the African American and the Male, respectively. The per capita number of fast food restaurants and their prices are effective factors to control the prevalence of obesity. For instance, an additional opening of fast-food restaurant (per 10,000 person) increases the PBF-defined obesity rate by 2.4% compared to 1.9% of the BMI. A dollar rise of fast-food price reduces the PBF-defined obesity rate by 5% compared to 2.7% of the BMI.

Conclusions: The obesity is far more prevalent in the United States and it is increasing slightly faster when measured by PBF, compared to BMI. Controlling the fast food restaurants and their prices is an effective tool to manage the prevalence of obesity.

Implications for Policy, Delivery, or Practice: A measure of fatness should be included in survey data for providing additional and helpful insights about the obesity prevalence change over time because NHANES III is available only until 1994. Regulating additional opening of fast food restaurants or raising a sale tax on the fast food is effective to reduce American's fatness in body.
A Discrete Choice Analysis of Cigarette Brand-Switching in China: Findings from ITC China Survey

Justin S. White, University of California at Berkeley; Jing Li, University of California at Berkeley; Teh-wei Hu, University of California at Berkeley; Geoffrey T. Fong, University of Waterloo, Canada & Ontario Institute for Cancer Research, Toronto, Ontario, Canada; Yuan Jiang, Center for Disease Control and Prevention, China

Presenter: Jing Li, M.A.,B.A., Student, Health Services and Policy Analysis, University of California at Berkeley, jingli86@berkeley.edu

Conclusions: As a result, the study found that S Hospital's reputation rested on for internal consumers, the physical factor, human factor, and connection factor; for external consumers, connection factor. For C Hospital internal customers relied on the human factor and connection factor and for external customers, human factor, accessibility factor, and connection factor largely contributing to the reputation of the hospital. As such, the differences in perception depending on region, internal and external customers indicate the need for specialized medical services to meet the demands of their needs. Therefore, the recognition and assessment of the customer's needs by the hospitals and adjustment in their marketing strategies are necessary.

Implications for Policy, Delivery, or Practice: Now not only do we need to make general hospitals competitive but we need to employ market strategies to increase the viability of small and medium sized regional hospitals by analyzing the hospitals that have gone through successful transitions. Also by changing the mindsets of regional health care consumers by making them think of turning to their regional hospitals first by satisfying the patient's needs, and hospitals deploying different positioning towards patients.

Funding Source(s): AHRQ

A Discrete Choice Analysis of Cigarette Brand-Switching in China: Findings from ITC China Survey

Justin S. White, University of California at Berkeley; Jing Li, University of California at Berkeley; Teh-wei Hu, University of California at Berkeley; Geoffrey T. Fong, University of Waterloo, Canada & Ontario Institute for Cancer Research, Toronto, Ontario, Canada; Yuan Jiang, Center for Disease Control and Prevention, China

Presenter: Jing Li, M.A.,B.A., Student, Health Services and Policy Analysis, University of California at Berkeley, jingli86@berkeley.edu

Research Objective: Understanding consumers' behavioral responses to cigarette prices is key to determining tobacco control and taxation policy. This study explores consumer choice among different price tiers of cigarettes in China. We investigate whether consumers who trade down to a cheaper cigarette brand resulting from longitudinal and geographic variation in China's price spread contributes to the country's relatively low price elasticity of demand for cigarettes. We further identify the socio-demographic sub-groups that are most likely to engage in this price-reducing behavior.

Study Design: We observe a smoker’s choice of cigarette brand at multiple points in time, and we use relative price variation across six cities over four years in China to identify the impact of cigarette prices on brand-switching. We construct tier-specific market cigarette prices using the median of smoker reported prices in each cigarette brand variety, which we argue are exogenous to bias in self-reported price. We employ a discrete choice framework to model smokers' choice among different cigarette price tiers, controlling for smokers' demographic characteristics. Our main results are derived from a mixed multinomial logit model that allows for random variation in individual preference and response to cigarette price.

Population Studied: This study focuses on adult urban smokers in China, although the results may be illustrative of urban smoking populations elsewhere. We use the first three waves of the International Tobacco Control (ITC) China Survey, conducted in six large cities in China between 2006 and 2009. The final analytical sample includes 3,477 smokers who are present in at least two waves (8,552 person-years).

Principal Findings: Overall, 38% of smokers switched price tiers from one wave to the next, including both trading down and trading up. A ¥1 (about $0.16) increase in the market price of a given cigarette tier is associated with 2 to 9 percentage points decrease in the probability of smokers' choosing that tier. There is significant variation in the magnitude of smokers' response to price. Smokers with higher income are more sensitive to cigarette price changes than those with lower income, whereas smokers with lower education are significantly more likely to engage in brand-switching in response to price change than are those with higher education.

Conclusions: China's large price spread across cigarette brands appears to alter the tier and brand selection of an un-negligible number of consumers, especially those with high income and those with low education. Our results offer predictions of the substitution patterns among different cigarette tiers in response to price changes, and provide a plausible explanation for
China’s relatively low price elasticity of cigarette demand found in previous literature.

**Implications for Policy, Delivery, or Practice:**
Tobacco pricing and tax policy can influence consumers’ incentives to switch brands. China’s current ad valorem taxes appear to widen the price difference between cigarette tiers, hence encouraging trading down. An increase in specific excise tax rates would likely discourage the practice.

**Public Reporting as a Communication Tool to Aid Vulnerable Consumers in Healthcare Decisions: The State of the Science**
Daniel Longo, Virginia Commonwealth University; Justin S. Lee, PhD, MSW, Benton College; Barbara A Wright, MLS, Virginia Commonwealth University

**Research Objective:** Objectives are to:
Determine if public reporting is utilized in making healthcare decisions by vulnerable consumers defined as African American, Latino and White populations with Type II diabetes; and
Determine the gaps in knowledge of healthcare public reports utilization by vulnerable populations
- Identify barriers and facilitators to help vulnerable diabetic populations make informed decisions about personal healthcare services

**Study Design:** A systematic literature review was conducted of relevant databases, reports, books, websites, and grey literature. In addition to examining websites containing reports, bibliographic databases were searched that included: MEDLINE, PsycINFO, Business Source Complete (EBSCOhost), CINAHL, The Cochrane Database of Systematic Reviews, and Web of Science®. These database searches utilized a combination of both index terms unique to the individual databases and text words or key words.

**Population Studied:** The criteria for the literature/information included in this review focused on:
publicly available reports or information to guide patient decision making; patients use of public reporting; vulnerable populations; diabetes type; peer-reviewed publications; and relevant ‘grey literature’ and/or web sites.

**Principal Findings:** With a search retrieval of over 8498 journal citations and other information sources, 473 citations were initially identified as addressing our objectives. Of these results, 79 citations were determined to be most relevant regarding gaps in knowledge of healthcare public report utilization by vulnerable populations.

**Conclusions:** Despite the large retrieval of potential relevant literature identified by our initial search (n=8498) after review and analysis only .009 percent met our inclusion and exclusion criteria. The literature review revealed: Despite 26 years of the availability of public reports, consumers today rarely use them and are generally unaware of the availability of such reports. There is little evidence that reports are designed for underserved population. Much work is needed to assist consumers in using consumer reports.

**Implications for Policy, Delivery, or Practice:**
The federal Patient Protection and Accountable Care Act has the stated mandate “to improve the dissemination of measures of healthcare quality and resource use, [and] to build the science of public reporting.” However, early studies on the design and use of consumer reports cite the public’s confusion and lack of understanding regarding the utility of such reports. Much added work is required.

**Reaching Out – Using the American Community Survey to Target Enrollment Efforts**
Elizabeth Lukanen, University of Minnesota

**Presenter:** Elizabeth Lukanen, M.P.H., Senior Research Fellow, State Health Access Reform Evaluation, University of Minnesota, elukanen@umn.edu

**Research Objective:** To highlight the American Community Survey (ACS) as a resource to target Medicaid and Exchange outreach. For states striving for universal coverage, the Affordable Care Act Medicaid expansion and insurance exchange provisions offer an excellent opportunity. As we have seen in the past, however, simply expanding eligibility doesn’t lead to maximized coverage gains. States will need to make a concerted effort to reach out to those who are eligible and educate them about the new coverage options. Given the cost of outreach, it is important for states to have a targeted outreach strategy. The
Objective of this paper is to illustrate how the ACS can identify the location of those likely to be eligible for Medicaid and for this exchange and to provide information on key characteristics of interest. In addition, the paper will explore other sources of information that can be used in conjunction with the ACS to further enhance outreach strategies.

**Study Design:** This paper uses three years of the American Community Survey data (2009 - 2011). Potential Medicaid and exchange eligibility is determined by insurance status (uninsured) and income, as defined by a health insurance unit. Descriptive analysis was conducted for select states at the lowest level of geography supported by the data (Public Use Microdata Area – PUMA) and by various characteristics of interest (e.g. age, sex, language proficiency, education, presence of school aged children in the household, receipt of other public programs, etc.). This analysis was mapped and select maps were overlaid with other information of interest (e.g. locations of schools, community center, major cities).

**Population Studied:** Uninsured, non-elderly, non-institutionalized, U.S. Citizens.

**Principal Findings:** In many states, exchange and Medicaid eligible populations are concentrated in specific locations and key patterns emerge at a sub-state level. In some states, the characteristics of individuals in the eligibility categories are similar; but in others, there are key differences. Within each eligibility category, characteristics also differ by geography. Layering maps of likely eligible participants with characteristics like schools and community centers help to illustrate other patterns useful for outreach planning.

**Conclusions:** The large state sample of the American Community Survey makes it an excellent resource in identifying the location of exchange and Medicaid eligible individuals at a sub-state level and to determine their characteristics. Layering these different types and levels of information can help guide effective outreach decisions. For example, you might find that the Medicaid eligible population is significantly older than the exchange-eligible population— in which case you may need separate outreach campaigns across different media outlets to reach each group. Or, if a significant number of Medicaid eligible uninsured are in a family with a school aged children— conducting outreach through schools might be an effective approach (this can be further enhanced by layering on a map of schools).

Assessing education levels across the two income groups can also be useful when considering literacy levels and complexity of outreach messages.

**Implications for Policy, Delivery, or Practice:** Many states are eager to utilize the ACA Medicaid expansion and insurance exchanges to expand coverage. By using the American Community Survey (free and publicly available), states can target their resources to develop a data-driven outreach and enrollment strategy.

**Implications of Undergoing Revision Joint Replacement at a Different Hospital**

Stephen Lyman, Hospital for Special Surgery; Kevin Bozic, UCSF; Christopher Dy, HSS; Timothy Wright, HSS; Robert G. Marx, HSS; Hung Do, HSS; Ting-Jung Pan, HSS; Doug Padgett, HSS

**Presenter:** Stephen Lyman, Associate Professor, Hospital for Special Surgery, lymans@hss.edu

**Research Objective:** The frequency with which patients undergo revision total joint replacement at a different hospital from where they underwent primary joint replacement deserves closer attention because of the financial burden associated with revision surgery. The safety of changing hospitals for revision joint replacement also needs to be better understood to inform regionalization strategies.

**Study Design:** A cohort of 509,211 patients who underwent primary total joint replacement between 1997-2005 in California and New York was identified from statewide all-payer discharge databases. Unique patient identifiers were used to identify referral to a different hospital for revision joint replacement during the study period. Diagnosis codes were used to identify complications following revision surgery. Patient characteristics (age, sex, race, comorbidities, insurance type, preoperative diagnosis), community characteristics (education level, poverty level, population density), and hospital characteristics (annual joint replacement volume, bed size, teaching status) were compared using regression modeling to determine predictors for referral for revision joint replacement and the effect of these referral patterns on complications after revision surgery.

**Population Studied:** All patients undergoing both primary and revision joint replacement in

**Principal Findings:** Revision occurred in 3.3% of all patients, with 30.4% of revisions performed at a different hospital from that of the primary surgery. Medicare and Medicaid patients were less likely to refer for revision than patients with private insurance. The most predictive factor for referral for revision at another hospital was time since surgery. Patients who had their primary surgery at large teaching hospitals and hospitals with high joint replacement volume were less likely to change hospitals. Hospital referral resulted in an increased risk (OR 1.30) of short-term complications following revision surgery. In exploring classes of complication, there was a significant increased risk of orthopaedic complications (OR 1.26) and other medical complications (OR 1.40).

**Conclusions:** The single most influential factor for undergoing revision at a different hospital was the time since primary surgery. Patients may change residences, insurance plans, or primary care provider while the processes underlying the cause for revision are developing. The decision to refer to another hospital may result in a higher likelihood of complication after revision surgery. This may reflect a relative unfamiliarity with the patient's medical conditions in the setting of a referred revision joint replacement.

**Implications for Policy, Delivery, or Practice:** Patients should be educated on the importance of compliance with long-term follow-up with the original treating surgeon. Further, strategies should be explored which would aid in maintaining a continuity of care to mitigate this risk. This provides further evidence of the inefficiency of care derived from a fractured fee for service payment system in which delivery is discontinuous over episodes of care.

**Poster Session and Number:** C, #990

**Potential Impacts of the ACA on Receipt of Recommended Preventive Care**

Stacey McMorrow, Urban Institute; Genevieve Kenney, Urban Institute; Dana Goin, Urban Institute

**Presenter:** Stacey McMorrow, Ph.D., Research Associate, Health Policy Center, Urban Institute, smcmorrow@urban.org

**Research Objective:** The benefits of many preventive health care services, including immunizations and screenings for cancer and chronic disease, are well-established. Despite this evidence, the use of many preventive services remains well below recommended levels. The Affordable Care Act (ACA) includes several provisions with the potential to improve receipt of recommended services, primarily by expanding access to affordable health insurance coverage. This paper examines the pre-ACA receipt of eight preventive services by non-elderly adults and considers the contributions of insurance coverage and other factors to their service use patterns.

**Study Design:** We use data from the 2005-2010 Medical Expenditure Panel Survey (MEPS) to measure the receipt of eight preventive services including blood pressure and cholesterol checks, mammograms and pap tests, and flu vaccines. We examine the gaps in receipt of preventive care for adults with incomes below 400 percent of the federal poverty level (FPL) compared to those with higher incomes. We then use a regression-based decomposition analysis to consider the factors that explain the gaps in service use by income. This technique allows us to identify how much of the gap in use between low and high income adults is explained by differences in their observable characteristics, including insurance coverage, education, age, and health status, and how much is due to other factors. We also use multivariate models to predict the change in service use if uninsured adults gain coverage as expected under the ACA.

**Population Studied:** We focus on non-elderly adults (18-64) with incomes below 400 percent of the FPL because they are the target of the ACA coverage expansions and compare their preventive service use to that for adults with higher incomes.

**Principal Findings:** Adults with incomes below 400 percent of the FPL were found to use preventive services at much lower rates than those with higher incomes. Our decomposition results suggest that differences in insurance coverage play a significant role in explaining the gaps in preventive service use between low and high income adults. Differences in age, education, and health status also play important roles, however. Our analysis also finds that covering the uninsured population with Medicaid or private coverage as intended under the ACA would increase preventive service use among the low-income population, but that use of some preventive services is still likely to fall below recommended levels.
Conclusions: Coverage is an important driver of preventive service use and the ACA coverage expansions are therefore expected to result in increased receipt of these services for those gaining new coverage or expanded benefits. However, the importance of factors other than coverage in explaining the gaps in preventive service use for low-income adults indicates that the ACA will not address all barriers to preventive care.

Implications for Policy, Delivery, or Practice: Promoting the importance of preventive care through education and awareness campaigns may help to improve adherence to prevention guidelines. However, the role of providers is critical to individual compliance and incentives for providers to adhere to screening guidelines may therefore prove important in eliminating remaining gaps in preventive care.

How Do Hospitals Compete for Patients?

Hint: It’s Not Based on Price or Quality
David Muhlestein, Ohio State University College of Public Health; Chrisanne Wilks, M.P.A., Ohio State University College of Public Health; Jason Richter, M.B.A., M.H.A., Ohio State University College of Public Health

Presenter: David Muhlestein, J.D., M.H.A., M.S., Doctoral Candidate, Division of Health Services Management and Policy, Ohio State University College of Public Health, muhlestein.1@osu.edu

Research Objective: Determine if price and quality information is available on hospital websites and identify the factors on which hospitals advertise to compete for patients.

Study Design: Review of hospital websites looking for advertising or information on price, quality, patient safety, customer satisfaction, personal stories, service, access, amenities, technology, research, awards, patient education, affiliations and employment opportunities.

Population Studied: Websites of a 10% simple random sample of all Medicare-registered hospitals.

Principal Findings: Only 1% of hospitals advertise or focus on price information while only 19% have hospital websites with any price information available on their website. Price information that is available is limited to billed charges for selected procedures, as opposed to negotiated rates, and no hospitals provide out-of-pocket estimates based on insurer. Quality information is advertised or focused on in only 6% of hospital websites while some quality data is available from 41% of hospital websites. The quality data that is available is limited to a few conditions and is aggregated at the hospital, not the physician, level. 57% of hospitals advertise for specific service lines, 50% advertise based on access and 31% advertise based on amenities. Hospitals do, though, advertise based on proxies for quality such as awards (34%) and advanced technology (24%).

Conclusions: Hospitals do not compete for patients on the basis of price or quality data and the information that is available is insufficient for consumers that do want to choose a hospital based on those factors. Hospitals primarily compete for patients based on services or amenities, indicating a focus on the patient experience of care.

Implications for Policy, Delivery, or Practice: Consumer-directed strategies, such as encouraging health savings accounts, have not led hospitals to compete on the basis of price or quality. Instead, hospitals compete for patients based on experience factors such as location, the quality of rooms or the attentiveness of staff. This may be because patients, at the time of needing hospital care, are more interested in those non-price, non-quality factors. A better approach is to shift the interest in consumer-directed care away from choosing providers at the point-of-service, and instead encourage patients to choose low cost, high quality providers much earlier, such as when they purchase health insurance, rather than waiting until they are sick.

Measuring Health Insurance Literacy: Understanding Consumers’ Ability to Choose and Use Private Health Insurance
Kathryn Paez, American Institutes for Research; Julie Goldstein, American Institutes for Research; Deepa Ganachari, American Institutes for Research; Coretta Mallery, American Institutes for Research; Harmoni Joie Noel, American Institutes for Research; Jennifer Lucado, American Institutes for Research; Eloisa McSorley, American Institutes for Research; Chris Pugliese, American Institutes for Research

Presenter: Kathryn Paez, Ph.D., R.N., Principal Researcher, Health Policy and Research, American Institutes for Research, kpaez@air.org
Research Objective: The research aim is to develop a validated measure assessing the health insurance literacy (HIL) of consumers in the private market. To achieve this aim, we researched the types of problems consumers face in selecting and using health insurance; developed a conceptual model of HIL; and drafted a 100-item pool of questions assessing HIL. As the result of the ACA, mostly low- and moderate-income Americans will have the opportunity to purchase insurance for the first time. Fulfilling the potential of this significant legislation hinges upon consumers’ understanding of health insurance and their options for coverage. Little empirical information is available about what consumers in the private marketplace actually do understand, or how organizations advising consumers and insurance carriers can move past the complexities and communicate insurance concepts and benefit language in a way consumers can apply to their own situations.

Study Design: This mixed methods study included interviews with health insurance counselors and focus groups with consumers. Results of our field test of the HIL measure with 600 consumers will be available by May 1, 2013.

Population Studied: We are studying consumers, age 18 to 65, who have or will purchase commercial health insurance and health insurance counselors working with these consumers. Twenty interviews were held with counselors working in four regions of the U.S. Three focus groups with the newly insured, people with families and those with chronic conditions were held in the mid-Atlantic region and California.

Principal Findings: Interviews with insurance counselors shed light on the challenges consumers experience selecting and using health insurance. Counselors noted that consumers fail to grasp the underlying concept of pooling risk to protect all. Consumers assess the value of insurance by looking at whether the costs incurred through the year for health services and drugs covered by insurance will match or exceed the monthly premium. Consumers frequently purchase insurance under the false assumption that they are covered for all the care they need because they pay a monthly premium. Insurance counselors attribute the assumption to lack of familiarity with provider networks, drug formularies, and authorization processes. Consumers put off reading about their plan benefits because they perceive it requires too much time and is too complicated.

Conclusions: Health insurance is one of the most complex products consumers will ever purchase. Consumers vary in their ability to make informed insurance decisions and navigate health insurance.

Implications for Policy, Delivery, or Practice: A body of evidence created by the use of a validated health insurance literacy measure will move the discussion from the nonspecific--“most consumers know little” and “health insurance is just too complicated”--to targeted action where information and outreach can be systematically tailored to the audience.

Psychological Attitudes Predict Smoking Cessation Over Time in the Women’s Health Initiative

Ana Progovac, University of Pittsburgh Graduate School of Public Health; Yue-Fang Chang, University of Pittsburgh; Karen Matthews, University of Pittsburgh; Michael Scheier, Carnegie Mellon University; Benjamin Chapman, University of Rochester Medical Center; Robert Wallace, University of Iowa; Catherine Messina, Stony Brook University; Hilary Tindle, University of Pittsburgh

Presenter: Ana Progovac, B.S., PhD Student, Health Management & Policy, University of Pittsburgh Graduate School of Public Health, amp164@pitt.edu

Research Objective: Low levels of optimistic attitudes and high levels of cynical attitudes toward others independently predict morbidity and mortality in Women’s Health Initiative (WHI) participants. At study entry, smokers were less optimistic and more cynical than nonsmokers. The present analysis examines whether
optimism and/or cynical hostility affected future smoking behavior among smokers, particularly postmenopausal women.

**Study Design:** WHI participants who were smokers at study entry (n=10,242) completed the Life Orientation Test-Revised (assessing optimism/pessimism (LOT-R)) and the Cook Medley cynical hostility subscale (both scores divided into quartiles). Multivariable mixed model logistic regression assessed self-reported smoking status (Y/N, ascertained by questionnaire) at 1, 3, 6 years after study entry, adjusted for baseline factors: age; ethnicity; education; insurance status; region; body mass index; cardiovascular disease, diabetes, cholesterol, or hypertension; any alcohol use; physical activity; and smoking pack years. Women were not specifically counseled to quit smoking through WHI.

**Population Studied:** WHI recruited 161,809 postmenopausal women during year 1994-1998 and followed them for up to 9 years in the main study. Women were between ages 50 to 79 years old at baseline, and the sample represents diverse racial, ethnic, and socioeconomic backgrounds across 40 recruiting centers in the United States. Exclusion criteria at enrollment included: substance abuse (aside from smoking or alcohol), mental illness, dementia, life expectancy less than three years, or not planning to live in the same area for at least 3 years. This analysis involves women who reported current smoking at baseline and who had information on psychological attitudes (n=10,242).

**Principal Findings:** On average, women were 61.0 years old (SD 6.8) and had smoked 28.9 pack years (SD 22.2). Over 6 years, 35.7% quit smoking. The least (vs. most) optimistic women were less likely to be high school graduates, physically active, white, insured, or to consume any alcohol (all p=0.001). They were more likely to report diabetes, hypertension, and obesity (all p=0.001) and greater pack-years (p=0.025). Least optimistic women were 33% less likely to quit smoking over time (OR=0.67 [0.56-0.81], p<0.0001), which held after adjustment (OR=0.72 [0.59-0.88], p=0.012). The most (vs. least) cynical hostile women closely resembled the least optimistic women on all factors. The most cynical women were also less likely to quit smoking over time in unadjusted (OR=0.58 [0.48-0.70], p<0.0001) and adjusted models (OR=0.60 [0.49-0.74], p< 0.0001).

**Conclusions:** The least optimistic and most cynical women were less likely to quit smoking over time. These findings underscore the role of psychological attitudes in longitudinal smoking behavior even among older adults.

**Implications for Policy, Delivery, or Practice:** More research is needed to investigate whether cessation programs that are tailored for attitudes (such as low optimism or high cynical hostility) are helpful. In addition, the extent to which psychological attitudes may be modified to assist in smoking behavior change is unclear, as are the precise interventions to effect this change. Whether psychological attitudes may help predict success in other populations (i.e., < 50, male, etc.) also requires further study.

**Patient Activation and Health Literacy as Predictors of Health Information Use in the Netherlands**

Jessica Nijman, NIVEL - Netherlands Institute for Health Services Research; Jany Rademakers, NIVEL - Netherlands Institute for Health Services Research; Michelle Hendriks, NIVEL - Netherlands Institute for Health Services Research; Anne Brabers, NIVEL - Netherlands Institute for Health Services Research; Judith de Jong, NIVEL - Netherlands Institute for Health Services Research

**Presenter:** Jany Rademakers, Dr., Head Of Research Department, NIVEL - Netherlands Institute for Health Services Research, j.rademakers@nivel.nl

**Research Objective:** To examine the relative contribution of patient activation and functional health literacy to the seeking and use of health information in the Netherlands.

**Study Design:** Survey study with self administered questionnaires in which patient activation was measured with the recently translated version of the Patient Activation Measure (Dutch PAM-13), functional Health literacy with the Dutch version of the Set of Brief Screening Questions (SBSQ) and the seeking and use of health information with a set of six statements and questions (Fowles et al. 2009): 1) “I find the internet an important source of information about health and illness”, 2) “I think I can recognize reliable websites about health and illness”, 3) “Do you read books about health and illness?”, 4) “I know where I can find information to compare the quality of care in hospitals.”, 5) “I know where I can find information to compare the quality of health care
Research Objective: In the national debate over rising healthcare spending, the time spent by patients seeking care (and the associated costs of this time) has not been adequately assessed. This time spent on medical care may negatively impact individuals and may result in lost productivity for employers and society. We quantified the time spent by adults seeking medical care for themselves, other adults, or children. Additionally, we estimated variation in time spent by socioeconomic status, and we quantified the cost of time spent.

Study Design: The American Time Use Survey is an annual nationally-representative survey by the Bureau of Labor Statistics. Respondents describe time use during the preceding 24 hours. Using 2003-2010 weighted survey data, we analyzed time spent waiting for and obtaining medical care ("visit time") and time traveling to medical care ("travel time") per visit when seeking care for themselves or another individual. We analyzed visit time stratified by respondent socioeconomic characteristics (education, income, race, age, and rural/urban residence). For employed respondents, we estimated the cost of visit and travel time ("total time") using reported wage data and imputing missing wage data using sociodemographic variables. We estimated total annual ambulatory visit counts and direct medical expenditures using the Medical Expenditure Panel Survey, allowing comparison of direct medical costs and time costs. Analyses accounted for population weights and survey design.

Population Studied: The sample consisted of 2000 members of the 'Dutch Health Care Consumer Panel' of NIVEL, the Netherlands Institute for Health Services Research. The sample was representative regarding gender and age for the Dutch population aged 18 years and older.

Principal Findings: More activated consumers were more likely to seek and use health information. Patient activation proved to be a stronger predictor for seeking and using health information than functional health literacy.

Conclusions: Health information use does not only depend on the level of reading skills, but also on other patient related characteristics such as feeling responsible for one’s own health, motivation to look for information and self-confidence to be able to ask questions.

Implications for Policy, Delivery, or Practice: Health communication strategies, both on an individual and on a public level, will have to address more aspects than literacy alone in order to be effective.

Funding Source(s): Other, Ministry of Health, Welfare and Sport (the Netherlands)

The Time Spent Receiving Medical Care in the United States and the Associated Time Costs

Kristin Ray, University of Pittsburgh School of Medicine, Children's Hospital of Pittsburgh; A. V. Chari, Ph.D., Rand Corporation; John Engberg, Ph.D., Rand Corporation; Marnie Bertolet, Ph.D., University of Pittsburgh Graduate School of Public Health; Ateev Mehrotra, M.D., MPH, University of Pittsburgh School of Medicine, Rand Corporation

Principal Findings: Among those seeking care, 49% were employed (n=1925). Based on hourly wages for those employed, the average total time cost per visit was $42 in 2010 dollars. On an annual basis among employed individuals, total time spent seeking medical care was 1.7 billion hours, and total time cost was $37.2 billion.

Conclusions: In the US health care system, the time spent seeking care and costs of this time are substantial. The time spent annually by employed individuals seeking care exceeded the number of hours worked by 800,000 full time employees. For every dollar of direct medical expenditures for outpatient care, 17 cents were
In 2006, Massachusetts residents increased from 86.6% in 2006 to 94.4% in 2010. Massachusetts residents are estimated to have a 7.6% increased probability of being insured compared to residents of neighboring states due to MA-HCR. However, the effect of an individual mandate on rates of insurance among trauma patients is unknown. We sought to examine whether or not an individual mandate would confer higher rates of insurance among injured patients.

**Funding Source(s):** Other, HRSA funded NRSA T32 Training Grant in Primary Medical Care

**Poster Session and Number:** C, #996

**Effect of an Individual Mandate on Rates of Insurance for Injured Patients**

Heena Santry, University of Massachusetts Medical School; Courtney E. Collins, MD, Department of Surgery, University of Massachusetts Medical School; Jason T. Wiseman, MD, Department of Surgery, University of Massachusetts Medical School; Charles M. Psoinos, MD, Department of Surgery, University of Massachusetts Medical School; Julie M. Flahive, MS, Department of Surgery, University of Massachusetts Medical School; Zeling Chau, MD, Department of Surgery, University of Massachusetts Medical School; Shimul A. Shah, MD, Department of Surgery, University of Massachusetts Medical School; Catarina I. Kiefe, PhD MD, Department of Quantitative Health Sciences, University of Massachusetts Medical School

**Presenter:** Heena Santry, M.D., M.S., Assistant Professor, Surgery and Quantitative Health Sciences, University of Massachusetts Medical School, heena.santry@umassmemorial.org

**Research Objective:** Policymakers theorize that comprehensive healthcare reform (HCR) will increase insurance rates among able-bodied, community dwelling adults 18-64 years old now mandated to purchase subsidized or unsubsidized insurance. Trauma is the leading cause of death and disability for these non-elderly Americans among whom marked socioeconomic disparities in both injury incidence and insurance rates have been documented. In 2006, Massachusetts implemented comprehensive HCR (MA-HCR) including an individual mandate. As a result of MA-HCR, insurance rates among Massachusetts residents increased from 86.6% in 2006 to 94.4% in 2010. Massachusetts residents are estimated to have a 7.6% increased probability of being insured compared to residents of neighboring states due to MA-HCR. However, the effect of an individual mandate on rates of insurance among trauma patients is unknown. We sought to examine whether or not an individual mandate would confer higher rates of insurance among injured patients.

**Study Design:** We undertook a retrospective cohort analysis of trauma registry data utilizing implementation of MA-HCR as a natural experiment. Manual review of discharge billing sheets was used to determine type of personal insurance, or lack thereof, at the time of injury. After excluding 2006-2008 as an implementation period, we compared rates of insurance between in-state residents and out-of-state residents in the pre-HCR period (2004-2005) and the post-HCR period (2009-2010) using univariate tests of association. Multivariable models estimated likelihood of insurance adjusted for demographic factors, injury mechanism, and severity.

**Population Studied:** Adult, non-elderly patients (18-64 years old) from central Massachusetts and surrounding states (NH, RI, CT, NY, VT) that did not implement HCR who were treated during the study periods at our level 1 trauma center located in central Massachusetts.

**Principal Findings:** There were 2,414 patients pre-HCR (11.0% out-of-state, N=266) and 2,745 patients post-HCR (9.8% out-of-state, N=268). In-state and out-of-state patients had similar age and sex distributions but out-of-state residents were more likely to be white (91.2% vs. 80.8%, p<0.0001), sustain blunt trauma (95.7% vs. 90.2%, p<0.0001), and present with severe injury (Injury Severity Score >25: 17.8% vs. 11.9%, p<0.0001). On univariate analyses, insurance rates increased for in-state residents post-HCR (76.7% (1647/2,148) to 84.3% (2088/2477), p<0.0001) and for out-of-state residents (77.4% (206/266) to 83.2% (223/268), p=0.094). In multivariable models including age, race, sex, mechanism of injury, and injury severity, residing in Massachusetts did not increase the odds of having insurance pre- or post-HCR.

**Conclusions:** In this single center study of trauma patients, overall insurance rates for
injured patients were significantly lower than those in the general population, both before and after HCR. We noticed a statistically significant increase in insurance rates from before to after MA-HCR in Massachusetts residents. A somewhat smaller increase for out-of-state residents was also observed but was not statistically significant, possibly due to limited sample size.

**Implications for Policy, Delivery, or Practice:** Further research should address the factors that may simultaneously increase risk of injury and preclude compliance with an individual mandate. Addressing these disparities when implementing insurance exchanges as part of the individual mandate accompanying federal HCR may improve insurance rates among non-elderly, able bodied community dwelling adults.

**Funding Source(s):** NIH

**The Growth of Publically Funded Participant-Directed Long-Term Services and Supports Programs in the United States**

Mark Sciegaj, Penn State; Isaac Selkow, Boston College; Kevin Mahoney, Boston College

**Presenter:** Mark Sciegaj, Ph.D., M.P.H., Associate Professor, Health Policy and Administration, Penn State, mxs838@psu.edu

**Research Objective:** Since 2000 numerous changes in federal law, regulation, and policy were implemented to promote the growth of participant-directed long-term services and support (PD-LTSS). However, in 2011 little was known about the actual number of PD-LTSS programs, the populations that they serve, their size, or their policies and procedures. To fill this gap, this study sought to create a comprehensive inventory of PD-LTSS programs in the United States.

**Study Design:** A mail/web survey of 300 program administrators was conducted.

**Population Studied:** The survey of state PD-LTSS administrators identified 212 PD-LTSS programs.

**Principal Findings:** The number of PD-LTSS programs has grown considerably since 2001. PD-LTSS programs serve all ages and types of disability. The number of participants enrolled in these programs has also grown considerably since 2001 but the majority of programs report enrollments of less than 500.

**Conclusions:** Federal policy and program changes have influenced the growth of programs.

**Implications for Policy, Delivery, or Practice:** Further research should address the factors that may simultaneously increase risk of injury and preclude compliance with an individual mandate. Addressing these disparities when implementing insurance exchanges as part of the individual mandate accompanying federal HCR may improve insurance rates among non-elderly, able bodied community dwelling adults.

**Community Level Quality Reporting and the Awareness and Use of Physician Quality Information among Individuals with Chronic Illnesses**

Yunfeng Shi, Pennsylvania State University; Dennis P. Scanlon, Pennsylvania State University; Neeraj Bhandari, Pennsylvania State University

**Presenter:** Yunfeng Shi, Ph.D., M.P.A., Research Assistant Professor, Pennsylvania State University, yus16@psu.edu

**Research Objective:** A tremendous amount of resources from all levels of governments and various private organizations have been dedicated to promoting public reporting of care quality. However, up to now, the overall impact of those efforts on care quality and consumer choice seems to be small or unclear. Our study examines consumers’ direct response to information change due to quality reporting. More specifically, we analyze how the change in the amount and relevancy of quality information is related to the change in consumers’ awareness and use of such information. We focus on physician quality information, which is less studied previously.

**Study Design:** We use a unique longitudinal data set built from two major sources: Aligning Forces for Quality Consumer Survey (AF4QCS) and Community Quality Reporting Tracking Database (AF4QTD). Aligning Forces for Quality (AF4Q) is a community based quality improvement initiative funded by the Robert Wood Johnson Foundation. AF4QCS has been conducted in two waves. The baseline survey was completed in 2008, with a 48% response rate. The second round was completed in 2012, with a retention rate of 60%. AF4QTD regularly tracks the number and contents of public and health plan reports released in 14 communities. We estimate our key parameters using a
Influence of Internet and Social Media Use on Patient Provider Communication among Racial/Ethnic Minorities
Sandhya Shimoga, University of California, Los Angeles

Presenters: Sandhya Shimoga, M.Sc MS, PhD Candidate, School of Public Health/Health Policy & Management, University of California, Los Angeles, sshimoga@ucla.edu

Research Objective: While there is some disparity in internet use among racial and ethnic minorities, it is reported often that once the initial barrier of use is removed, use of internet and social media is associated with improved communication among all patients. Current study aims to add to the relatively small number of empirical studies that address such relationships. Study objectives include examining - i) whether there are any differences by race/ethnicity in the use of internet for seeking health related information and ii) whether social media use is associated with better communication with providers. I hypothesize that compared to Whites, racial and ethnic minorities use internet to a lesser extent to seek health related information, and trust health information from the internet to a lesser extent, controlling for SES and other factors. Also, social media use is associated with better communication with providers with no difference with respect to race or ethnicity, controlling for SES and other factors.

Study Design: Data on 3,959 adults from the 2012 Health Information National Trends Survey (HINTS) administered by National Cancer Institute are used for this study. To address the first hypothesis, multivariate logistic regression were conducted with use of internet, use of internet in the past 12 months and trust in internet resources as the outcome variables with race as primary regressor. To address the second hypothesis, ordered logistic regressions were conducted with social media use as the primary regressor and measures for patient communication as outcome variables.

Population Studied: Nationally Representative Adult Sample (n=3,959)

Principal Findings: There was no significant difference by race in the use of internet for seeking health related information. However, Hispanics were found to have lower trust in information on health from internet compared to whites (OR = 0.7, p < 0.05) and similar result was found for other minorities excluding African Americans; there was no significant difference found between African American and White patients in terms of trust. Social media users were found to report higher chances of being able to ask all their questions during healthcare consultations compared to non users (OR p<0.1) and there was no difference between racial groups. Having a regular provider was the most significant predictor of other communication measures such as the ease of understanding provider instructions or being able to be involved in their healthcare decisions.

Conclusions: While use of internet for seeking health information is prevalent among all groups, minorities seem to trust such information to a lesser extent. This may be due to language
barriers or not being able to understand information which is predominantly in English. Moreover, even if they have access to non-English information, there was no information on whether communication with provider happened with the same language. As this is a cross sectional study, it could not be ascertained whether trust in internet resources precedes or follows the use of internet.

**Implications for Policy, Delivery, or Practice:**
Encouraging the use of internet and social media may reduce racial disparities in some aspects of patient provider communication.

**Enrollment in Medicare Advantage Plans in Miami-Dade County: An Accident of Birth?**
Anna Sinaiko, Harvard School of Public Health; Christopher Afendulis, Ph.D., Harvard Medical School; Richard Frank, Ph.D., Harvard Medical School

**Research Objective:** Evidence from behavioral economics reveals that decision-making in health sector choice environments can be affected by circumstances and choice architecture. We characterized the choice set of Medicare Advantage plans (MA) in Miami-Dade County in 2004-2008, a period when MA became more generous than traditional Medicare (TM) in terms of expected out-of-pocket costs (OOPC) and benefits provided. We then analyze the demand for MA to assess impact of timing, active versus passive decision-making, and other individual characteristics on choice of MA.

**Study Design:** We use a unique dataset on the plan choices of all Medicare beneficiaries to estimate logistic regression models of the probability that a beneficiary is enrolled in MA. Dependent variables include whether a beneficiary enrolled in MA within their first twelve months of eligibility for the program and remain continuously enrolled in MA (which we term being in the “incident cohort”), whether they were enrolled in MA in the previous year, the relative cost of MA vs TM, beneficiary age, race, and the year they became eligible for Medicare. Models include year fixed effects for the period of our data; standard errors are clustered at the beneficiary level.

**Population Studied:** We include all Medicare beneficiaries in Miami-Dade County age 65+ during 2004-2008, except those eligible for Medicaid, the long-term institutionalized, and those enrolled with an insurer outside of Miami-Dade. We analyzed 1,028,772 elderly person-year observations, or about 171,000 beneficiaries per year.

**Principal Findings:** The number, diversity, and generosity of MA plans in Miami grew between 2004 and 2008, including those without physician network restrictions. Among new MA enrollees each year, slightly more than half are from the incident cohort each year and the remainder switch in from TM. Individuals who joined MA during their incident year are significantly more likely than those in the non-incident cohort to be enrolled in MA (marginal effect = 0.08, p<0.001), as are beneficiaries in MA in the prior year (marginal effect 0.28, p<0.001) For beneficiaries in TM, the probability of switching into MA significantly decreases with each year of tenure in Medicare (p<0.05).

**Conclusions:** Becoming eligible for Medicare is the key transition point for MA. Because of the timing of when they aged into Medicare, those beneficiaries turning 65 in 2004-08 disproportionately benefited from entering MA, while those already in Medicare were most likely to be the ones leaving money on the table.

**Implications for Policy, Delivery, or Practice:** The effects of health plan search frictions such as inertia and defaults suggest that policy that helps enrollees in TM overcome a "default" option of staying in TM, evaluate MA options and decide to switch plans will be important to achieving an efficient marketplace for MA plans, for it will create incentives for MA plans to compete for all beneficiaries and not just the newest. Such policy may also make non-incident beneficiaries better off.

**Promoting High-Value Choices to Consumers: Consumer Testing and Education**
Jennifer Stephens, American Institutes for Research; Jill Yegian, American Institutes for Research; Cailin Falato, American Institutes for Research; Lee Thompson, American Institutes for Research
Research Objective: Health reform is expected to reshape health care delivery by aligning provider, purchaser, and consumer incentives to encourage more efficient, evidenced-based care. Much of the cost information that is available has not been meaningful or compelling to consumers—it is not personal nor does it reflect their out-of-pocket costs. There is, however, evidence that demand for cost information is growing among certain populations of consumers, including those with shoppable conditions (e.g., knee replacement), high out-of-pocket costs, and those in search of a new doctor. This study focuses on how consumers respond when presented with public reports of cost information and how coalitions are successfully engaging consumers in making high value choices.

Study Design: AIR conducted 27 one-on-one, 90-minute interviews with health care consumers over three rounds of testing in York County, PA; San Mateo, CA; and Memphis, TN. We asked consumers about the types of costs they search for and consider, where they get that information, and how they view quality of care in terms of cost. Consumers were shown displays of quality and average costs of care for hospital procedures and displays of quality and costs of doctor office visits. Using this information, three coalitions used the information from this and other research to create training sessions to help consumers understand and choose high value care.

Population Studied: We recruited consumers between 18 and 64 years old and a mix of gender, race/ethnicity, education, household income, chronic disease (existence and type), and health insurance type. Consumers showed a vested interest in health care costs (e.g., confirmed that they pay some or all of their health care costs out-of-pocket).

Principal Findings: Our findings suggest that consumers are more likely to understand and apply cost information to make high value (high quality, affordable cost) health care choices that represent their out-of-pocket costs. Consumers are more likely to understand and use cost information in public reports when reports contain quality information, alongside cost information and feature clear labeling and reflect measures relevant to the consumer. Consumers are highly unlikely to change their physician if they have an established relationship even in the face of this information.

Conclusions: There are several ways in which coalitions can support informed decision-making and promote high value choices by consumers: 1) educate both consumers and employers on the importance and availability of high-value health care; 2) target consumers who are responsible for paying for some portion (or all) of the costs of a service out-of-pocket; 3) describe high-value care to consumers as “high-quality care at an affordable cost;” 4) display quality, cost, and other comparative information (e.g., location, office hours) together on a single page; and 5) advocate for collecting and reporting measures that are more compelling and actionable for consumers.

Implications for Policy, Delivery, or Practice: Insurers, employers, providers, and coalitions can educate and encourage consumer choices of high value care through educational programs and advocacy for relevant reporting measures. Programs that engage consumers over a series of training sessions and teach about health insurance, quality, cost, may impact consumer selection of high value care.

Geographic Distance as a Barrier to VA Women's Health Care Use

Donna Washington, VA Greater Los Angeles Healthcare System & UCLA; Su Sun, VA Greater Los Angeles Healthcare System; Martin Lee, VA Greater Los Angeles Healthcare System; Michael Mitchell, VA Greater Los Angeles Healthcare System; Mark Canning, VA Greater Los Angeles Healthcare System; Elizabeth Yano, VA Greater Los Angeles Healthcare System

Presenter: Donna Washington, M.D., M.P.H., Physician, Professor Of Medicine, Medicine, VA Greater Los Angeles Healthcare System & UCLA, donna.washington@va.gov

Research Objective: Women veterans’ numerical minority within the VA creates challenges to providing universal VA access to women’s health services (WHS). We investigated the influence of distance to VA WHS on women veterans’ VA use.

Study Design: Using a population-based, cross-sectional design, we surveyed 2,174 women veterans about demographic
characteristics, healthcare systems used (VA, non-VA, none), and chronic conditions (none, medical only, mental health). Using geographic information system techniques, we calculated their driving distance to the nearest VA site and to the nearest VA site offering WHS. Administrative data provided VA facility and services used. Multinominal logistic regression identified predictors of use. Zero truncated negative binomial regression estimated effect on number of VA visits for VA users.

**Population Studied:** Population-based sample of 2,174 women veterans (VA users and VA nonusers) residing in southern California or southern Nevada.

**Principal Findings:** The median distance to the nearest VA site was 8.5 miles (range 0.1-161; interquartile range 8.1), and to the nearest VA site with on-site WHS was 19.3 miles (range 0.1-252; interquartile range 23.3). For 58.7% of women veterans, the nearest VA site did not offer WHS. Greater distance to VA sites delivering WHS predicted WHS use outside the VA for those with mental health conditions or with no chronic conditions. Adjusting for age, chronic conditions, and VA priority group, for each 10 mile increase in distance to VA WHS, the relative risk ratio (RRR) favoring no WHS use versus VA use was 1.16 (95% confidence interval [C.I.] 1.03-1.3), and the RRR favoring WHS use outside VA was 1.15 (95% C.I. 1.1-1.2). Among VA users, lack of WHS at the closest VA site was associated with use of more distant sites that offered on-site WHS. Use of VA sites without WHS was associated with lower adjusted visit rate (incidence rate ratio 0.6; 95% C.I. 0.4-0.8).

**Conclusions:** We found geographic barriers to meeting women veterans’ chronic care needs. Lack of close proximity to VA WHS deterred use, particularly among those with mental health comorbidity. Concentration of services at a limited number of sites also led to preferential VA medical center over community-based outpatient clinic use.

**Implications for Policy, Delivery, or Practice:** Interventions to increase access require identifying strategies for ensuring that designated primary care providers with appropriate women’s health expertise are available in geographically dispersed VA sites. Virtual education modalities and virtual support for provision of specialty care services are promising interventions to achieve these aims.

**Re-Defining Cost and Quality: The Intersection of Consumer Decision-Making, Science, and Art**

Catherine West, Center for Health Information and Analysis; Marjorie Radin, Center for Health Information and Analysis

**Presenter:** Catherine West, Director Of Health Systems Policy And Stakeholder Relations, Health Systems Performance, Center for Health Information and Analysis, catherine.west@state.ma.us

**Research Objective:** In an effort to improve healthcare cost and quality transparency and help consumers and providers to make more efficient decisions, one provision of Massachusetts’ healthcare cost containment legislation calls for a consumer health information website designed to share a variety of cost and quality data. Existing websites with similar objectives address quality but not cost, or address both but have substantial gaps that limit their utility. We examined cross-sector experiences to identify these gaps and develop possible solutions.

**Study Design:** Beginning in September 2012, we conducted a comprehensive literature review to develop an interview guide. We conducted one-on-one key informant interviews with 26 stakeholders, analyzed commentary from 18 stakeholders who responded to our Request for Information, and evaluated 19 existing state and national websites.

**Population Studied:** Stakeholders included Massachusetts health plans, provider organizations, researchers, consumer advocacy organizations, state and national foundations, state and federal agencies, and vendors.

**Principal Findings:** To effectively promote more efficient decision making in healthcare spending, consumer healthcare websites must be both useful and used, two related but distinct objectives. Profound shortcomings exist in both of these areas. Stakeholders indicate that consumers need price and quality information presented together in an easily understandable manner that allows for comparisons. Display is important and simple information is more effective for consumers to understand and utilize. Moreover, total costs and costs to insurers are not immediately relevant to most consumers. Perhaps most significantly, consumers do not use websites they do not know exist. Physicians may not understand the
Association between Local Area Unemployment Rates and Use of Veterans Affairs Primary and Mental Health Care

Conclusions: To improve usefulness, health plan data should be standardized to offer comparative data, and the website should display out-of-pocket costs rather than total cost or insured cost. To improve usability, websites should not assume that patients understand how to access the health care system and data should be plan- (or product-) specific. Data should also be integrated with sites or mobile apps where consumers are already going for reliable and effective health information. Further research may be needed to determine exactly how best to define a target audience, assess consumer-driven needs, and further the goal of more rational, better-value health care consumption with the ultimate goal of better quality (in terms of outcomes and satisfaction) at lower cost.

Implications for Policy, Delivery, or Practice: As states seek to engage consumers in the ACA drive to improve value in healthcare, understanding the gaps in information and evidence-based strategies for outreach are critical. Future policy endeavors, including the Massachusetts consumer website, a plan-based total cost estimator tool, and other public and private consumer engagement initiatives could benefit from considering the various stakeholder perspectives solicited for this study. Collaboration is critical to creating a web-based tool that is meaningful. Focus groups with consumers, followed by end-user testing, implementation and evaluation are next steps.

Study Design: This retrospective cohort study analyzed utilization of primary and mental health care. Using VA administrative databases, we calculated repeated quarterly utilization measures at the facility-level as the total number of visits for patients assigned to a primary care clinic. We measured local area unemployment rates (LAURs) quarterly for each facility as the unemployment rate in the labor market area in which a primary care clinic was located. The impact of the LAUR on VA utilization was examined by estimating fixed effects negative binomial models to account for clinic-level heterogeneity. All regression models adjusted for clinic characteristics (average age, proportion male, clinic size, average patient risk, and clinic type (hospital-based or community-based)) and seasonal variation. To account for differences in VA utilization due to Medicare eligibility, all analyses were performed separately among patients below and above 65 years of age. We then calculated incidence rate ratios, which reflected the percent change in quarterly utilization due to a unit increase in the LAUR, holding all other variables constant.

Population Studied: We used the VA Primary Care Management Module to identify 8,493,362 unique patients receiving care from 972 primary care clinics during Fiscal Year (FY) 2003 to FY2012.

Principal Findings: The mean number of facility-level visits was increasing over time for
all utilization categories and age subgroups. Between FY2003-Quarter 1 (Q1) and FY2012-Q4, the mean number of visits increased from 1,931 to 2,674 for primary care and 1,918 to 3,049 for mental health, among patients under age 65. Between FY2003-Q1 and FY2012-Q4, the mean number of visits increased from 2,412 to 2,493 for primary care and 351 to 738 for mental health, among patients age 65 and over. After covariate adjustment, a one percentage point increase in the LAUR was associated with a 0.96% (p<0.001) increase in primary care visits among patients under 65, but was not associated with primary care utilization among patients over age 65 (-0.10%, p=0.228). For mental health, a one percentage point increase in the LAUR increased visits by 2.06% (p<0.001) for the under age 65 group and 0.81% (p<0.001) for the over age 65 group.

Conclusions: LAURs were associated with increases in primary care utilization among veterans under age 65 and mental health utilization for all veterans.

Implications for Policy, Delivery, or Practice: Collectively, our results highlight the importance of the state of the economy for fiscal planning of government health programs including VA.

Funding Source(s): VA

Poster Session and Number: C, #1006
2009 resulted in approximately 4,580 new enrollees statewide. The calculated enrollment elasticity was 0.058. Therefore, from the lowest average unemployment rate of 4.1 in 2006 to the peak of 11.9 in 2009, an increase of 174 percent, resulted in an increase in the average number of enrollees by just under 10 percent. For every 1 percentage point increase in the unemployment rate, total program expenditures increased 2.1% (p < 0.001). Changes in types of health care expenditures included a 2.8% increase for prescription drugs (p < 0.001), 2.4% for hospital care (p < 0.107), 2.2% for dental services (p < 0.001), 1.9% for outpatient care (p < 0.001), and 1.6% for emergency department services (p < 0.005).

**Conclusions:** ALL Kids enrollment was influenced by county unemployment. This suggests many Alabama families lost insurance coverage and experienced declines in income following job losses. As a result, ALL Kids saw modest expenditure increases. This increase in enrollment occurred despite the number of children in families whose incomes fell sufficiently for them to qualify for Medicaid.

**Implications for Policy, Delivery, or Practice:** The ALL Kids program can use these estimates to anticipate changes in enrollment with rising or falling unemployment rates within Alabama counties. Additionally, projected changes in expenditures can be anticipated in developing the program’s budget.

**Drivers of Health Insurance Coverage in the Decade Prior to the Affordable Care Act**

Fredric Blavin, The Urban Institute; Stacey McMorrow, The Urban Institute; Sharon Long, The Urban Institute; Genevieve Kenney, The Urban Institute

**Presenter:** Fredric Blavin, Ph.D., Research Associate, Health Policy Center, The Urban Institute, fblavin@urban.org

**Research Objective:** The last decade saw large increases in uninsurance rates for adults driven primarily by a decline in the rate of employer-sponsored insurance (ESI). The Affordable Care Act (ACA) is intended to reverse these declines in insurance coverage, but its success will depend on how it addresses the key determinants of recent changes in insurance coverage. Prior research has identified many of the drivers of coverage changes in the 1980s and 1990s, including premium growth, Medicaid expansions, labor market factors, and macroeconomic forces. In this paper, we examine the determinants of coverage changes from 2000 to 2010 and use the results to consider the likely effects of the ACA on insurance coverage overall and for lower-income adults.

**Study Design:** We use data from 2000-2010 Current Population Survey (CPS) to measure changes in insurance coverage and collect data from a variety of sources to capture key determinants of health insurance coverage. We model changes in any, private, and public coverage from 2000-2010 and consider the role of demographic, economic and policy factors in shaping pre-ACA coverage trends. We pay particular attention to the role of changes in premiums, health care costs, and Medicaid eligibility over the last decade as these are the factors most likely to be affected by the ACA.

**Population Studied:** We limit our analysis sample to non-elderly adults ages 19-64 as this is the population targeted by the ACA coverage expansions.

**Principal Findings:** The past decade saw an increase in the nation’s uninsured of nearly 13 million. Results from a descriptive decomposition analysis show that as much as half of this growth in the uninsured appears to be driven by secular changes that led to declines in ESI and that would have led to even greater increases in uninsurance had Medicaid/CHIP not expanded to cover more children and adults.

For the multivariate analysis, we hypothesize that health care costs, overall and as reflected in premiums for private coverage, and eligibility for public coverage will be key factors in explaining trends in health insurance coverage over the last decade. Preliminary data shows rapidly increasing health care costs over the period, combined with a limited expansion of Medicaid eligibility for adults. At the same time, private coverage, including ESI, has declined, with public coverage and uninsurance both growing. Consistent with prior research, we also expect to find that the growth in the unemployment rate and falling incomes during the most recent recession will have had a significant impact on ESI and overall coverage rates.

**Conclusions:** Understanding the impacts of the ACA on insurance coverage will require understanding the structure of the market in which the ACA will be implemented. Trends in
insurance coverage leading up to the ACA reflect the complex interaction of individual and market forces, along with significant state variation in coverage policy.

**Implications for Policy, Delivery, or Practice:**
While we expect the ACA to yield a substantial increase in insurance coverage in 2014, addressing the underlying drivers of declining health insurance coverage, including rising health care costs, will be central to ensuring that those gains are maintained over time.

**Medicaid Undercount in the American Community Survey: Initial Results**

Kathleen Thiede Call, University of Minnesota; Michel Boudreaux, University of Minnesota, SHADAC; Joanna Turner, University of Minnesota, SHADAC; Brett Fried, University of Minnesota, SHADAC

**Presenter:** Kathleen Thiede Call, Ph.D., Associate Professor, State Health Access Data Assistance Center, University of Minnesota, callx001@umn.edu

**Research Objective:** Surveys provide the only source of data describing the distribution of health insurance in the general population and change in coverage over time necessary for evaluating the impact of health reform. The American Community Survey (ACS) is the newest federal survey to add questions about health insurance. The large sample size of the ACS makes it a unique source for understanding coverage dynamics at the subgroup level. However, measuring health insurance coverage is challenging and virtually every survey undercounts Medicaid enrollment. If enrollees do not report Medicaid, estimates of other coverage or being uninsured will be biased upwards and Medicaid estimates will be biased downwards. The extent of the Medicaid undercount in the ACS is currently unknown. We use ACS which has been linked to Medicaid administrative data to describe (1) the extent that the ACS undercounts Medicaid enrollment; (2) the type of coverage reported for those not reported as being Medicaid enrolled; and (3) the geographic and demographic correlates of misreporting.

**Study Design:** We use linked 2008 ACS (the first year health insurance variables were available) and monthly Medicaid Statistical Information System (MSIS) data. This allows us to examine the extent of the Medicaid undercount in the ACS for people enrolled in Medicaid (MSIS) at the time of the survey and what insurance coverage (e.g., private or other public), if any, is reported if not Medicaid. We conduct bivariate and multivariate analysis to examine the correlates of misreporting. We compare the ACS results to published results from the other federal surveys.

**Population Studied:** Non-institutionalized Medicaid population.

**Principal Findings:** Preliminary results suggest that the Medicaid undercount in the ACS tracks closely to undercount estimates from other surveys. The percent of Medicaid enrollees for whom Medicaid is accurately reported varies across surveys and is reasonably high (approximately 75%) in surveys like the ACS, MEPS and NHIS that ask about coverage at the time of the survey and lower in the CPS (57%) that asks respondents to refer back to coverage in the prior calendar year, and results vary by subgroup. The percent of Medicaid enrollees for whom lack of insurance is erroneously reported is low leading to modest upward bias to estimates of uninsurance.

**Conclusions:** This study provides a first look at Medicaid undercount in the ACS. Measuring health insurance is challenging and valid estimates of coverage and coverage dynamics are critical to evaluating health reform efforts. This study indicates that error in Medicaid reporting in the ACS is lower than the CPS and similar to the NHIS and MEPS.

**Implications for Policy, Delivery, or Practice:** Although there is some upward bias in estimates of uninsurance, the bias is modest and consistent with results from other national survey that measure insurance at a point-in-time (ACS, NHIS and MEPS) as compared to the CPS that require that respondents report on health insurance 15-18 months prior to the survey. The level of accuracy and consistency with other national surveys should provide policymakers confidence in using the ACS data to evaluate the impact of the Affordable Care Act (ACA) at the national and state level.

**Perspectives on Co-Management for Rural Veterans from Primary Care Providers in Iowa: A Mixed Methods Study**

Mary Charlton, University of Iowa College of Public Health/Iowa City VA; Anne H. Gaglioti, Department of Family Medicine, University of
Involving quantitative survey data and qualitative study design:

**Study Design:** A mixed methods design involving quantitative survey data and qualitative data from semi-structured telephone interviews was used to elicit information from non-VA providers.

**Population Studied:** Survey instruments were mailed to 270 non-VA primary care providers (PCPs) participating in a Midwestern rural practice based research network in 2011. Providers were asked to indicate if they were willing to participate in a telephone interview.

**Principal Findings:** Of the 270 PCPs in the network, 67 (25%) completed questionnaires and 21 (7%) completed a subsequent interview. Providers who completed the written questionnaire were primarily physicians (94%), predominantly male (76%), and had an average of 19.9 years of service at their current practice. Survey responses indicated 74% found communication with VA to be “poor” or “non-existent” and 42% percent believed poor communication with VA has resulted in poor patient outcomes. Interviews underscored the patient as the main vehicle for information transfer between providers; a practice not viewed as ideal. Non-VA providers felt they were interacting with VA as a system rather than communicating with VA providers as individuals, which they attributed to an inability to identify/access VA providers directly. Interview respondents described their role in caring for veterans as providing continuous care as well as acute, urgent, or emergency care due to limited access to these services at the VA.

**Conclusions:** VA system barriers appear to hinder communication between providers across systems, possibly resulting in fragmented care. Community-based, non-VA PCPs who are caring for rural veterans are frustrated by the lack of communication and care coordination with the VA system and have come to rely on the patient as the vehicle of communication between providers.

**Implications for Policy, Delivery, or Practice:** In light of the expansion of VA healthcare benefits for returning veterans, expansion of Medicaid coverage under the Affordable Care Act, and the continued disproportionate contribution of rural counties to the ranks of active military recruits, the population of rural veterans using (both) VA and non-VA systems will continue to increase. By addressing barriers to communication between VA and non-VA systems with education, outreach, and systems-based improvements, the burden of communication could be transferred from the veteran patient to a less haphazard and medically safer venue. In turn, this could...
potentially result in improved care coordination, patient and provider satisfaction, and improved veteran health outcomes.

Recession Associated Health Care Expenditure Reduction in the United States: Access vs. Intensity

Jie Chen, University of Maryland at College Park

**Presenter:** Jie Chen, Ph.D., Assistant Professor, Health Services Administration, University of Maryland at College Park, jichen@umd.edu

**Research Objective:** The great economic recession 2007-2009 is the longest recession in the United States (US) history. Recent statistics showed that total health care expenditures in US decreased during the recession. This study is going to (1) examine whether recession-associated health expenditure reductions differ along the distribution of health care expenditure. Particularly, we were interested to see whether the health care expenditure reduction was more substantial at the lower end of health care expenditure (proxy for health care access or preference for preventive care) and/or at the higher end of health care expenditure (proxy for intensiveness or quality of care). (2) examine whether racial and ethnic disparities in health care expenditure persisted or deteriorated during the recession.

**Study Design:** We used the nationally representative data set of Medical Expenditure Panel Survey of 2005-2006 and 2008-2009. Our outcome variables were the annual health care expenditures: total health care costs, and costs on different types of health care services, i.e. physician visits, prescription drug, outpatient visit, inpatient visit, and emergency department (ED) visit. Quantile multivariate regressions were employed to estimate the different associations between recession and health care expenditures along its distribution. Race/ethnicity and other covariates were controlled to examine whether recession had different impacts on health expenditures for the minorities.

**Population Studied:** Our analysis included adults aged 18 to 64 years old.

**Principal Findings:** Recessions were significantly associated with lower health care expenditure at the lower end of the distribution (17%, 15%, and 4% reduction of health care expenditure at the 10th-50th percentile of the distribution), but not at the higher end of the health care. Racial and ethnic disparities were more substantial at the lower end of health expenditure. The reduction of health care expenditure was similar for all race/ethnicity. Recessions were associated with significant decrease in prescription drug cost, and it was associated with higher physician costs at the 50th percentile and above. Recessions were significantly positively associated with ED costs along the distribution of health care expenditure.

**Conclusions:** The recession was associated with substantial reduction in receiving primary care, indicating the possible deteriorating health care access induced by the recession, especially among people without health insurance. Our results did not show that recession was associated with the expenditure reduction among those requiring large amount of health care resources. Prescription drug cost reduction might indicate the likelihood of substituting generic drugs for expensive brand name ones, especially among the racial and ethnic minorities. Higher ED costs during the recession suggested the importance to restore the efficiency of providing health care access. Increased physician expenditures at the higher end of the distribution might show some evidence of physician supplier induced demand. Racial and ethnic disparities faced substantial barriers in health care access compared to the whites, and these disparities persisted during the recession.

**Implications for Policy, Delivery, or Practice:** Our results provided evidence that Affordable Care Act has the potential to buffer the disproportionate reductions in health care cost induced by the economic downturn.

Financial Burden of Medical Care: A Family Perspective

Robin Cohen, National Center for Health Statistics; Whitney Kirzinger, National Center for Health Statistics; Renee Gindi, National Center for Health Statistics

**Presenter:** Robin Cohen, Ph.D., M.S., Statistician, Division of Health Interview Statistics, National Center for Health Statistics, rcohen@cdc.gov

**Research Objective:** Recently published data from the National Health Interview Survey
Health insurance coverage provides a means for mitigating financial risk associated with health care costs. As more persons gain coverage under the Affordable Care Act (ACA), it is important to monitor the financial burden of medical care. This paper will explore family and person level demographic characteristics and their association with financial burden of medical care.

Study Design: This study used NHIS data, which are nationally representative of the civilian noninstitutionalized population. Data were derived from the NHIS Family component, which collects information on all family members in each household. In 2011, three new questions addressing financial burden of medical care were added to the NHIS Family component. These questions addressed problems paying medical bills, paying medical bills over time, and having medical bills that cannot be paid at all. A composite measure of any financial burden was developed based on a positive response to “problems paying medical bills in the past 12 months” or a positive response to “currently have medical bills that are being paid over time.” For those families that currently have medical bills being paid over time, there may not be negative consequences. In 2011, information was collected on 40,496 families and 101,875 persons.

Population Studied: Civilian noninstitutionalized resident population of the United States

Principal Findings: Based on the person level analysis, children aged 0–17 years were more than three times as likely as adults aged 75 and over to be in families having problems paying medical bills in the past 12 months. Analysis on a family level confirmed these findings, as families with children are more likely to experience financial burden for medical care than families without children. The highest level of financial burden for medical care was found in families between 100%-199% of the federal poverty level (near poor). Families with mixtures of health insurance coverage types (e.g. some members with private health insurance and other with public coverage) experienced greater financial burden than those families where all persons had private health insurance. Additional analyses using logistic regression techniques are still underway to examine an individual’s age, race and ethnicity, and health status with financial burden of medical care and a family-based complementary examination of family health insurance status, family composition, size, and poverty level and their associations with financial burdens for medical care.

Conclusions: Families with children, near poor families, and families who have a mixture of health insurance coverage types within the family unit are the most likely to experience financial burden.

Implications for Policy, Delivery, or Practice: One of the goals of ACA is to make medical care for affordable (through subsidies, tax credits, and provision of essential health services). The NHIS can be used to monitor the financial burden of medical care in the United States as new provisions of the law become effective.

Funding Source(s): No Funding

State Variation in Perceptions of Health Insurance Coverage by the Uninsured: Implications for the Affordable Care Act

Peter Cunningham, The Center for Studying Health System Change; Amy Bond, Center for Studying Health System Change

Presenter: Peter Cunningham, Ph.D., Senior Fellow, The Center for Studying Health System Change, pcunningham@hschange.org

Research Objective: Prior research has shown that whether people have positive or negative perceptions of health insurance strongly influences whether they enroll in coverage or remain uninsured. The purpose of this paper is to examine variation across states in the percent of uninsured who agree that (1) they are healthy enough that they don’t need health insurance, and (2) health insurance is not worth the cost.

Study Design: Analysis of the 2002-2009 Medical Expenditure Panel Survey. MEPS has the capability of producing state-specific estimates for the 29 largest states. Multiple years of the MEPS are pooled to increase state-specific samples of the uninsured and the statistical precision of estimates. Estimates of state variation in perceptions of health insurance coverage by the uninsured adjust for differences in characteristics of the uninsured, including their age, health status, prevalence of chronic conditions, family income, race/ethnicity, and general tolerance of risk.

Population Studied: Adults age 18-64 who were uninsured the entire year.
**Principal Findings:** Nationally, about 18 percent of the uninsured say that they do not need health insurance, while 38 percent say that health insurance is not worth the cost. However, there is considerable variation across states in these perceptions. The percent of uninsured who say they do not need health insurance ranges from about 12 percent in the state of Tennessee to 27 percent in Colorado. The percent who say that health insurance is not worth the cost ranges from about 31 percent in Tennessee to 46 percent in Pennsylvania. Differences in characteristics of the uninsured across states explain some but not all of the state variation in perceptions. Additional analysis suggests that there are differences across states in the “culture of insurance” that influences perceptions. For example, the uninsured have more favorable perceptions of health insurance coverage in states where (1) the insured population also have favorable perceptions; (2) a higher percentage of small businesses offer coverage to workers, and; (3) state Medicaid spending on low income populations is greater.

**Conclusions:** The results of this study show that perceptions of health insurance coverage by the uninsured – and therefore whether they are likely to enroll in the ACA’s coverage expansions – vary considerably across states. Most of the variation is not explained by differences in the characteristics of uninsured people, and to some extent reflects differences across states in the culture of health insurance coverage.

**Implications for Policy, Delivery, or Practice:** The Affordable Care Act will increase insurance coverage through expansions of Medicaid eligibility and premium subsidies for uninsured people. Federal and state governments have a variety of strategies planned and underway to encourage enrollment in the new coverage options. Despite tax penalties for failing to enroll, some states are likely to encounter greater resistance from their uninsured populations in enrolling in coverage, and should emphasize strategies that include educating and promoting the value and importance of insurance coverage.

**Drug Access, Medication Adherence and Medical Expenditures for Medicare Patients with Congestive Heart Failure**

Timothy Dall, IHS Global Insight; Paul Gallo, IHS Global Insight; Tericke Blanchard, IHS Global Insight; Samantha Shoemaker, Pharmaceutical Research and Manufacturers of America; Jennifer Bryant, Pharmaceutical Research and Manufacturers of America

**Research Objective:** It is widely acknowledged that increasing appropriate use of medications offers significant opportunity to improve health outcomes and realize greater value from our healthcare system. However, research consistently demonstrates that prescription medications are often not used as directed. Congestive heart failure (CHF) represents one example of a prevalent and costly condition for which there is room for improvement in ensuring adequate levels of medication adherence. Evidence suggests adherence rates are in the range of 50%-70%. Medicare Part D exemplifies one opportunity to increase access to and use of medications, and a growing body of literature suggests this to be the case. This study quantifies the healthcare utilization and expenditure implications of Part D implementation for patients with CHF.

**Study Design:** Using the 2006-2010 Medical Expenditure Panel Survey (MEPS), we identified a nationally-representative sample of individuals diagnosed with CHF (N=1,012). In combining empirical analysis with evidence derived from peer-reviewed literature, we examined the relationship between Part D, medication utilization, and use of other healthcare services. We stratified the study sample to estimate average expenditures per encounter and rates of utilization for hospitalizations, emergency visits, ambulatory visits, and home health visits. Cost data were obtained from the MEPS and 2010 Nationwide Inpatient Sample (n=71,147 with CHF as the primary diagnosis), applying hospital-specific cost-to-charge ratios to estimate average expenditures per hospitalization. A microsimulation procedure was utilized to estimate the impact of Part D and subsequent increases in medication utilization on the probability and rate of use for other healthcare services.

**Population Studied:** Approximately 2.2 million people in the U.S. were diagnosed with CHF in 2012, of which approximately 1.3 million are in the Medicare program.

**Principal Findings:** CHF-related medical expenditures totaled $6.5 billion in 2012.
(including $3.7 billion for Medicare patients). Based on review and analysis of literature, the implementation of Part D was associated with a 10.0% weighted average increase in prescriptions used to treat CHF annually and a 9.6% increase in total annual prescriptions. The impact of Part D on drug utilization was over three times greater among CHF patients with no or limited prior coverage. Additionally, we calculated that Part D reduced CHF expenditures by approximately 2% (or $60/CHF beneficiary in Medicare for a total of $73 million in savings annually. Despite increased medication use, adherence levels remain suboptimal. Improving adherence to reach target levels (80% or better) could reduce CHF-related health care use by 7.6% ($491 million among the entire CHF population and $278 million among Medicare beneficiaries annually).

**Conclusions:** Establishment of Part D had a significant impact on improving adherence to medications prescribed to treat CHF, and results in reductions in healthcare use, overall medical expenditures, and saved lives. **Implications for Policy, Delivery, or Practice:** Improved access and adherence to treatment regimens can reduce potentially avoidable hospitalizations, emergency visits, and other healthcare use. These findings support the value of implementing programs or policies aimed at improving appropriate medication use. **Funding Source(s):** Other, Pharmaceutical Research and Manufacturers of America **Poster Session and Number:** C, #1021

**Potential Impact of the Affordable Care Act on Non-Elderly Adult Cancer Survivors**

Amy Davidoff, Agency for Healthcare Research and Quality; Steven Hill, Agency for Healthcare Research and Quality; Didem Bernard, Agency for Healthcare Research and Quality; K. Robin Yabroff, National Cancer Institute

**Presenter:** Amy Davidoff, Ph.D., Senior Economist, Center for Financing, Access and Cost Trends, Agency for Healthcare Research and Quality, amy.davidoff@ahrq.hhs.gov

**Research Objective:** Adults with active cancer or a cancer history may face limited insurance options due to difficulties gaining or sustaining employment, reduced offers of employment related insurance (ESI), particularly in small firms, and/or difficulty purchasing insurance in the non-group market. We examined existing health insurance options, and the potential of the Affordable Care Act (ACA) to improve access to insurance for cancer survivors through adult Medicaid expansions and insurance exchange subsidies. **Study Design:** We used data from the 2008-2009 Medical Expenditure Panel Survey (MEPS) household component. Adjusted gross income, modified to include Social Security payments, was used to compute income as a percent of the federal poverty level (%FPL). Federal and state specific Medicaid and CHIP eligibility rules were applied to relevant income and assets to identify currently eligible survivors. To assess eligibility under the ACA, respondents were stratified based on income relative to the threshold of 138% FPL (Medicaid), 400% FPL (subsidized insurance exchanges), and >400% FPL (unsubsidized insurance exchange) with adjustments for citizenship and immigrant status. Insurance-related hardship was based on reported delays or unmet need for medical, prescription, or dental care in a 12 month period, and/or out-of-pocket burden that was 20% or more of simulated after-tax income. Weights adjusted for multiple responses. **Population Studied:** The cohort included cancer survivors aged 18-64 years identified as “ever told by a physician that you had cancer.” **Principal Findings:** The cohort included 1694 cancer survivors, 65% female, 83% white non-Hispanic, 62% currently married. 69% had employment related insurance (including Tricare), while 16% were uninsured. Overall 19% of cancer survivors reported either delayed or forgone healthcare due to costs or insurance issues, including 39% of the uninsured. Overall 14% of cancer survivors were eligible for Medicaid or CHIP pre-ACA, including 12% of the uninsured. Two-thirds of the cohort had offers of ESI from employers, including 34% of the uninsured. Assuming full implementation of the Medicaid expansions, 22% would be Medicaid eligible under the ACA, including 42% of the uninsured. One third of cancer survivors would be eligible for the subsidized participation in the insurance exchanges, as would 39% of the uninsured. Of those reporting a financial access burden, 49% would be eligible for Medicaid under ACA, and an additional 35% would be eligible for subsidized participation in insurance exchanges. **Conclusions:** A substantial proportion of non-elderly adult cancer survivors were uninsured and the uninsured disproportionately report financial burdens or reduced access to care. A small portion of the uninsured failed to takeup
available public coverage, while one third did not enroll in offered ESI. Under the ACA, most of the uninsured, and an even larger proportion of those facing access problems would be eligible for Medicaid or subsidized insurance.

Implications for Policy, Delivery, or Practice: Full implementation of the ACA would dramatically enhance insurance availability, and be likely to reduce access barriers for vulnerable adults with cancer. Further research on take-up of currently available Medicaid or employment related insurance will help to inform likely effects of ACA on realized insurance coverage for cancer survivors.

Barriers to Providing Contraceptive Care Under the Women’s Health Waiver

Ruth Eudy, University of Arkansas; Loretta Alexander, UAMS College of Public Health; Victoria Evans, Hendrix College

Research Objective: The Arkansas Medicaid Women’s Health Waiver (WHW), begun in 1997 as the Family Planning Waiver, has resulted in significant reductions in unwanted pregnancies and over $743 million in cost savings through Demonstration Year 2011. However, although the number of private providers participating in the WHW has steadily increased, approximately 80% of women who receive family planning services through the WHW continue to use local public health clinics. Previous evaluation reports noted private provider turnover rates between 26% and 36%, rates not easily explained by available data. The Centers for Medicare and Medicaid Services (CMS) asked the evaluators to determine the reasons private providers may elect not to participate. Subsequently, the evaluation team included a survey to determine private providers’ knowledge of WHW services and what they perceived as barriers to participation.

Study Design: A population-based survey was conducted using Dillman survey methods, with mail and telephone follow-ups. Quantitative data analyses included descriptive statistics, Chi-Square tests for differences in proportions and t-tests for differences in means. Qualitative data analysis included sorting open-ended responses by typology or theme.

Population Studied: All Arkansas-licensed and practicing physicians, registered nurses and nurse practitioners providing health services to women of childbearing age.

Principal Findings: Among physician respondents 73% did provide reproductive health services. Among those who did, 88% were aware of the WHW. However, only 39% participated. Among nurse respondents 65% provided reproductive health services; 83% of these were aware of the WHW; and 42% participated. Respondents were asked to select reasons they believe that providers may have difficulty participating. Both physician and nurse providers rated all barriers higher than the mean of 3 on a 5-point Likert scale. For both groups, the only significant difference between WHW participants and non-participants was that non-participants were significantly more likely (t = 4.07 , p < 0.0001 for physician non participants; t = 2.58, p < .01 for nurse non-participants) to find that problems with billing Medicaid were barriers, not the actual reimbursement rates or other attributes of the WHW services.

Physicians were more likely (t = 2.26, p < 0.03) to perceive that the WHW’s lack of coverage for health conditions other than reproductive health is a barrier to provider participation. Nurses were more likely (t = -2.05, p < 0.05) to find that problems with reimbursement were a barrier. The survey concluded with one open-ended question soliciting comments about barriers to participation. The most common themes in the qualitative responses were lack of knowledge about the program and concern about providing or referring for services that weren’t covered.

Conclusions: Although a majority of providers are aware of the WHW, fewer than 50% participate. Physicians find the limited coverage under the waiver to be a barrier to providing care; other providers cited reimbursement issues as the primary barrier.

Implications for Policy, Delivery, or Practice: These findings will serve to inform providers and policy makers as we move forward with implementation of contraceptive care measures as an integral part of preventive care within the Affordable Care Act.

Evaluation of the Children’s Health Insurance Program (CHIP) Outreach and Enrollment Grant Program: Cycle I Grantees
Janet O’Keefe, RTI International; Kathleen Farrell, RTI International
**Presenter:** Kathleen Farrell, Project Director, RTI International, kfarrell@rti.org

**Research Objective:** Conduct a formative evaluation to determine effective strategies to enroll and retain eligible children, identify major challenges and methods to overcome them, and identify key lessons learned about outreach and application assistance that can be used to inform other initiatives.

**Study Design:** Reviewed grant applications, and quarterly, annual, and final reports on grant activities and outcomes over the two year grant period. Collected additional information from grantees through telephone interviews and e-mail communications. Synthesized information from grant reports and grantee interviews into standardized annual and final report summaries.

**Population Studied:** 68 Cycle I grantees, including nonprofit community-based organizations, state primary care associations, legal aid organizations, and county and state agencies.

**Principal Findings:** In states that have enrolled a high percentage of the eligible CHIP/Medicaid population, it is extremely difficult to locate and enroll the remaining eligible children. Specifically tailored methods and strategies to contact the remaining hard-to-reach eligible uninsured children are needed. Outreach and education are important, but not sufficient to increase enrollment. Face-to-face assistance leads to more completed applications because many people have difficulty completing the paperwork. The uninsured, CHIP/Medicaid-eligible population is not homogeneous so multiple strategies are needed to find and enroll eligible uninsured children, particularly those in rural and remote areas and in hard-to-reach groups. Prior to implementing initiatives, it is essential learn what types of outreach and assistance strategies work best with the targeted audience, and customize marketing strategies and materials to meet their specific needs. An enrollment strategy that is effective at one time in one area may not be effective elsewhere or at other times. Even what seems to be the most culturally appropriate, community-focused outreach strategy may not yield the anticipated number of uninsured eligible children. Despite best efforts, some strategies will not work due to factors that cannot be controlled, although assessing the circumstances may provide information that can be used to modify the approach or use it in a setting where it might be more successful.

**Conclusions:** Major shifts in numbers (positive or negative) are the result of major policy changes, such as expanding eligibility to permit parents to enroll or creating a fast-track eligibility determination process. Although community-based efforts play an important role, the ease or difficulty with which uninsured children can be enrolled and stay enrolled are the most important factors. Allowing families to self-declare income and using searchable databases to document identity and citizenship would help to reduce denials because of lack of required documents. Renewals would be facilitated by state policies that allow passive renewals; pre-populated renewal forms; allowing parents to call-in renewal information; 12 month continuous eligibility; and “re-set the clock” policies that allow renewals for another 12 months at any time during the year, for example, when a child uses health services.

**Implications for Policy, Delivery, or Practice:** The findings provide policymakers, state officials, and other stakeholders with important insights into effective approaches for enrolling eligible children, which can be applied as the ACA is implemented.

**Medicaid Reimbursement Policy for Statins: Implementation and Utilization Impact**

Michael Fischer, Brigham and Women's Hospital/Harvard Medical School; Jennifer M. Polinski, Brigham and Women's Hospital; Lindsay Ritz, Brigham and Women's Hospital; Niteesh K. Choudhry, Brigham and Women's Hospital; Sebastian Schneeweiss, Brigham and Women's Hospital

**Presenter:** Michael Fischer, M.D., M.S., Associate Professor Of Medicine, Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital/Harvard Medical School, mfischer@partners.org

**Research Objective:** State Medicaid programs struggle to control medication costs, often using policy tools such as prior authorization (PA) or preferred drug lists (PDL) to direct drug use. It is unclear whether these policies succeed in reducing the use of overly expensive medications or encouraging the use of highly effective generic medications. Statins, the most

**Funding Source(s):** CMS
widely used lipid-lowering medications, offer a useful case study since both generic and brand-name options are available with differing costs but similar efficacy.

**Study Design:** Detailed policy data were collected from state Medicaid agencies on whether PA or PDL policies were in place for specific statins from 2002-2009. State-level aggregate Medicaid drug use data for each calendar quarter in each state were obtained from the Centers for Medicare and Medicaid services. We evaluated the impact of PA or PDL policies on the composition of statin prescribing (branded statins as a percentage of all statins), and on the cost of statins (statin cost per prescription).

**Population Studied:** 50 Medicaid programs (49 states plus DC).

**Principal Findings:** At the start of 2002, 13 states had statin-specific policies in place (7 with PA, 5 with PDL, 1 with both) and 37 states had no policies. Implementation of both types of policies increased sharply in 2003-2004 and at the start of 2005 only 10 states had no policies while 34 states had both PA and PDL for statins. At the end of 2009 just 3 states had no policies in place. Statins accounted for 2-3% of all Medicaid prescriptions from 2002-2005, with similar rates in states with and without policy. Statin use dropped in all states in 2006 as older patients obtained Medicare drug coverage, averaging 1.5% of prescriptions through the end of the study period.

States using PA policies alone used 20% fewer brand-name statins (75% vs 95%) than other states until late 2006, at which time generic simvastatin became available. In early 2007 use of brand-name statins equalized across states and declined in parallel from 70% to 40% by the end of the study period. Cost per statin prescription was similar across states initially and decreased in all states after generic simvastatin became available. By the end of 2009 the average cost per statin prescription was $61 in the three states with no statin policy and $55 in states using both PA and PDL policies.

**Conclusions:** States that used PA policies for statins had initial success in controlling the use of more expensive brand-name versions, but these effects were swamped by the generic availability of simvastatin, one of the most widely used agents in the class. Most states implemented both PDL and PA policies, though the rates of brand-name statin use and cost per prescription were similar in these states compared to states with no policy.

**Implications for Policy, Delivery, or Practice:** Some Medicaid policy tools can affect the medications used by beneficiaries, but our results do not show large and consistent impacts on medication costs. Since there are substantial administrative costs to implementing these policies, further studies using patient-level data will be required to determine whether these policies are changing clinical decision-making and are cost-effective for Medicaid programs.

**Funding Source(s):** AHRQ

**Multiple Risks, Multiple Jeopardy: Effect of Medical Shocks on Meeting Basic Needs in a Time of Recession**

**Ashley Fox, Mount Sinai School of Medicine; Mark J. Schlesinger, Yale University**

**Presenter:** Ashley Fox, Ph.D., M.A., Assistant Professor, Health Evidence and Policy, Mount Sinai School of Medicine, ashley.fox@mount Sinai.org

**Research Objective:** Although a good deal of research has examined the effect of being uninsured, few studies have assessed the economic and health-related impacts of large medical expenses on insured Americans. These can affect Americans lives in three distinct ways: (1) as additional medical costs not covered by insurance, (2) as additional costs for rising insurance premiums, and (3) as losses of earnings that coincide with medical expenses, if serious illness keeps people from working. Drawing on a unique panel dataset collected in the wake of the recent economic crisis, the objective of this research was to examine the impact of large medical expenses on insured Americans’ well-being, a problem arguably left unaddressed by the ACA.

**Study Design:** The Survey of Economic Risk Perceptions and Insecurity (SERPI), was fielded as part of the nationally representative American National Election Survey (ANES) 2008-2009 Panel Survey. Given its panel design, the dataset allows for an analysis of the timing of economic and health sequelae following the experience of incurring a recent large medical expense or a co-occurring loss of earnings associated with being too sick to work. Outcome measures included economic harms (losing one’s house, being evicted, unpaid bills, deep indebtedness, draining retirement), health harms
(refraining from going to the doctor, bringing one’s child to the doctor, or buying medications because of cost), basic needs (hunger and food insecurity) measured in 2009. Controls included gender, race, age, education, household income and wealth, measured in 2008.

**Population Studied:** A random sample of 2,203 adult Americans completed the survey.

**Principal Findings:** Eight percent of the sample experienced a large out-of-pocket medical expenditure, 10% experienced an increase in the cost of coverage, and 7% lost time from work due to illness or injury in the past 6 months. Insured individuals who had experienced a large out-of-pocket medical expenditure were four times more likely to be suffering from moderate food insecurity and twice as likely to report not having bought drugs because of cost. Individuals who had experienced an increase in the cost of coverage were more likely to be hungry and experience severe food insecurity, and to have not taken a child to the doctor because of cost and financial problems. Individuals who have been kept from work because of an injury were more likely to report moderate food insecurity and having lost their home.

**Conclusions:** Even without among those with health insurance, large medical expenditures resulted in significant economic hardship and negative health-related coping behaviors. Few of these economic strains are addressed by the Affordable Care Act, where, in spite of large subsidies to purchase health insurance up to certain thresholds, many are concerned that health insurance will continue to put significant financial strains on households that can compromise their health and economic stability.

**Implications for Policy, Delivery, or Practice:** Continuing to look for ways to smooth medical costs to consumers and reduce cost inflation will be necessary to diminish the economic and health related sequelae associated with rapidly rising costs of health care.

**The Impact of Retail and Urgent Care on Conventional Primary Care Appointment Availability**

Ari Friedman, University of Pennsylvania; Karin V. Rhodes, Perelman School of Medicine, University of Pennsylvania; Daniel Polsky, The Wharton School, University of Pennsylvania

**Presenters:** Ari Friedman, B.A., MD/PhD
Student, Wharton Health Care, University of Pennsylvania, abfriedman@gmail.com

**Research Objective:** Traditionally, patients seeking general outpatient care have turned to conventional primary care clinics (PCCs), which provide scheduled, longitudinal, outpatient care. Patients’ ability to obtain timely access to their primary care provider has declined, however. Retail clinics (RCs) and urgent care clinics (UCCs), which treat similar conditions but which emphasize unscheduled, episodic care, have developed to fill this gap. Little is known about how RCs and UCCs affect access, which patients these clinics serve, and whether PCCs respond to RC and UCC entry (for instance, they might reorganize to increase appointment availability).

This study investigates the interrelationships between three aspects of access to primary care: appointment wait times (days to next available appointment), geographic accessibility, and insurance acceptance.

**Study Design:** Clinic locations were obtained from Merchant Medicine (UCCs), SK&A Healthcare (PCCs), and directly (RCs). The Area Resource File supplied county provider density (mid-level and physician providers per capita). The 2010 Census furnished population counts and demographics. InterStudy provided county insurance proportions. To measure appointment availability, we made over 10,000 telephone calls to traditional primary care clinics (PCCs, not RCs or UCCs) using simulated patients. Calls were randomized by scenario (urgent primary care versus less urgent) and insurance status (Medicaid, private insurance, and uninsured).

To assess the impact of RC and UCCs on PCC appointment wait times, we will match PCCs close to RC/UCCs to those far from one, then compare outcomes via Weibull regression. Matching will be based on clinic provider count, and area characteristics (population, income, urbanicity, provider density, and percent elderly, Hispanic, and black).

We also regressed clinic counts against controls for area characteristics (as above) via negative binomial regression for all 784 counties in the ten study states.

**Population Studied:** Non-elderly, non-pediatric population in ten states.

**Principal Findings:** RCs and UCCs contributed to more geographic availability of episodic care in rural states. For example, 13 percent of
Montanans have a UC within 5km, compared to 65 percent for PCCs. Whereas for Massachusetts, 3 and 95 percent of the population have an UC or PCC within 5km. In county regressions, RCs and UCCs were significantly more likely to serve areas with high uninsurance than were PCCs. Complete data from the telephone study will be available in early March 2013. We will then assess the impact of proximity to RC and UCCs on appointment availability by insurance status using the matching strategy. We will also estimate how much further each individual must travel to reduce their PCC appointment wait time by one day. By re-estimating this statistic with the addition of RCs and UCCs, we will quantify their contribution to greater access.

Conclusions: The addition of for-profit unscheduled care to the primary care landscape has altered the choices available for some patients. RCs and UCCs appear to serve a more disadvantaged population than do PCCs.

Implications for Policy, Delivery, or Practice: RCs and UCCs have the potential to increase access, but may also fragment care due to their lack of a longitudinal relationship. Policymakers should prioritize interoperable health information technology and increased payment for care coordination to mitigate these effects.

Gender Differences in Healthcare Cost, Use, and Insurance Coverage
Paul Gorrell, IMPAQ International LLC; Laney Light, IMPAQ International

Presenter: Paul Gorrell, Ph.D., Senior Research Scientist, Health Data & Systems Analysis, IMPAQ International LLC, pgorrell@impaqint.com

Research Objective: To investigate gender differences in healthcare cost, use, and insurance coverage in order to increase our understanding of the policy implications of changes in health insurance as they affect men and women 45-64 and 65 and over.

Study Design: The Medical Expenditure Panel Survey (MEPS) is a nationally representative survey of the civilian, non-institutionalized, population. This study uses recently released data for 2010 to generate person- and event-level estimates of healthcare cost, use, and insurance coverage. The study analyzes data by gender for two age groups: 45-64 and 65 and over. Data were analyzed using statistical software which accounts for the complex design properties of MEPS and generates valid variance estimates. Weighted, nationally-representative estimates are reported overall and by gender for the specified age ranges.

Principal Findings: This study presents a detailed look at gender differences in healthcare cost, use, and insurance coverage among adults 45 and over. It is well documented that healthcare costs are not evenly distributed among the population. Consistent with prior work, we find that in 2010 the top 5% of the civilian population ranked by their healthcare expenditures account for 50% of all healthcare expenditures. Overall women represent 51% of the civilian (and MEPS) population but account for 54% ($707 billion) of the $1.26 trillion in 2010 civilian healthcare spending. Prior studies have associated this with the difference in life expectancy (80 years for women; 75 for men). However, we report a similar pattern for the 45-64 population, with women accounting for 56% of healthcare expenditures (and 51% of the 45-64 population). This difference cannot be due to life expectancy differences. We also report significant gender differences in the patterns of use and insurance coverage among both age groups. Hospital inpatient stays and prescribed medicines account for over half of all expenditures. More than 1 in 4 (27%) of the top 5% had 2 or more inpatient stays in 2010, with females comprising 71% of those with 2 or more hospital stays. Women had more hospital stays on average in 2010, but among those with an inpatient stay, men in each age group had higher per-person and per-stay costs, as well as longer lengths of stay. Women 45-64 had higher per-person prescribed medicine costs, but the gender difference was not significant for the 65-and-over population. We also report important differences in insurance coverage for the 45-64 age group, with almost 10% of women on Medicaid at some point in 2010, compared with 5.8% of men. Women were significantly more likely than men to have only public insurance coverage for all of 2010.

Conclusions: A detailed investigation of gender differences among men and women 45-64 and 65 and over reveals a complex pattern of cost, use, and insurance coverage differences that cannot be accounted for by any single factor such as differences in longevity. In particular,
different patterns emerge for the 45-64 population with women accounting for the majority of overall costs, but men, for example, having higher per-person and per-stay costs for inpatient stays. With respect to insurance coverage, changes in Medicaid and public insurance options will affect a higher percentage of women than men based on the reported findings.

**Implications for Policy, Delivery, or Practice:**
The results of this study extend current knowledge and increase our understanding of gender differences in cost, use, and insurance coverage for the two age groups studied. Understanding the reported patterns will be important for assessing the potential differential effects on women and men in these age groups as healthcare reform progresses and changes in Medicaid and other insurance options are implemented. Further, they indicate the importance of clearly understanding healthcare cost, use, and coverage patterns among policy-relevant subpopulations in assessing potential effects of ACA implementation nationally, as well as with respect to State variation in Medicaid expansion.

**Measuring the Impact of Language Access Regulations on HMO Enrollees with Limited English Proficiency**
Max Hadler, UCLA Center for Health Policy Research; Xiao Chen, UCLA Center for Health Policy Research; Erik Gonzalez, David Geffen School of Medicine at UCLA; Dylan H. Roby, UCLA Center for Health Policy Research

**Presenter:** Max Hadler, MPH, MA, Research Associate, Health Economics and Evaluation Research Program, UCLA Center for Health Policy Research, mhadler@ucla.edu

**Research Objective:** Evaluate California’s preparedness to incorporate newly-insured populations with limited English proficiency (LEP) under the Affordable Care Act by measuring LEP individuals’ ability to understand their physicians in the wake of a state law requiring commercial HMOs to provide qualified interpretation and translation services. We also developed a sociodemographic and health status profile of LEP populations according to health insurance coverage to help planning for language access services.

**Study Design:** We used data from the 2007 and 2009 California Health Interview Survey (CHIS) to compare language access of LEP respondents before and after enforcement of language access regulations began. Data from 2009 were used to develop a demographic profile of LEP enrollees in four public and private insurance categories. Pairwise tests of proportions measured change from 2007 to 2009 and differences within the 2009 LEP population.

**Population Studied:** All CHIS respondents ages 18-64 who reported speaking English not well or not at all – a representative sample of the California population for that group.

**Principal Findings:** From 2007 to 2009, the proportion of LEP enrollees in the four categories of insured respondents – commercial HMO (8.3% to 9.0%), commercial preferred provider organization (PPO; 4.4% to 4.8%), public HMO (23.9% to 27.2%), and public fee-for-service (23.8% to 25.2%) – trended upward but not significantly. Difficulty understanding doctor trended downward for commercial HMOs (12.1% to 9.5%) but also not significantly. Looking only at 2009 (the most recent year available), LEP enrollees in commercial HMOs were significantly less likely to have trouble understanding their doctor if they were in excellent, very good, or good health compared to LEP enrollees in fair or poor health. Just over half of LEP enrollees in commercial HMOs (56%) who needed help communicating with their doctor reported receiving help from trained staff or professional interpreters.

**Conclusions:** The lack of significant change in difficulty understanding doctor among LEP enrollees in commercial HMOs suggests that language access regulations have yet to affect health care communication barriers. The overlapping timing of the regulations and CHIS surveying may partially explain the results because some responses referred to physician visits that happened before regulations were fully enforced by the Department of Managed Health Care (DMHC). Other factors, including persistent use of family members and untrained health plan staff as interpreters, may also explain the continued struggle for language access. DMHC monitoring has confirmed that health plans admit to continued gaps in staff training. The disparity in understanding among LEP enrollees in fair or poor health underscores the importance of special focus on LEP populations with complex health issues.
Implications for Policy, Delivery, or Practice: CHIS and the language access regulations are specific to California, but the state has been a leader in language access issues. These results have important implications for other states looking to bridge persistent language access gaps. The timing is particularly important in the context of the Affordable Care Act as an increasing number of LEP individuals gain insurance and greater access to health care services through qualified commercial health plans. Effective language access regulations and enforcement are crucial to ensuring high-quality care for these vulnerable groups.

State Variation in Potential for ACA Reforms to Address High Burden Medical Out-of-Pocket Spending: Results from the Current Population Survey

Lacey Hartman, State Health Access Data Assistance Center; Gilbert Gonzales, University of Minnesota, Division of Health Policy and Management; Sharon Long, Urban Institute

Presenter: Lacey Hartman, Senior Research Fellow, University of MN, State Health Access Data Assistance Center, hartm042@umn.edu

Research Objective: To use new state level data on out-of-pocket spending from the Current Population Survey to estimate the potential impacts of the Affordable Care Act (ACA) reforms on high burden spending across states.

Study Design: In order to examine the potential for the ACA to alleviate high burden spending, we apply statutory premium and out-of-pocket spending limits included in the ACA to simulate spending amounts for people who are likely to be income-eligible for Medicaid, premium assistance subsidies, or caps on non-premium spending beginning in 2014.

Population Studied: We use 2010 and 2011 data from the Current Population Survey (CPS) to produce state level estimates of the share of the population with high burden out-of-pocket spending, which we define as spending more than 10% of family income on health care. The CPS is a monthly household survey that the Census Bureau conducts for the Bureau of Labor Statistics to provide data on labor force participation and unemployment. Information about out-of-pocket spending and health insurance coverage is collected through the Annual Social and Economic Supplement (ASEC).

Principal Findings: We find the share of the population with high burden spending would decrease in all states with full implementation of the policy changes under the ACA. We also find that the median out-of-pocket spending would decrease from $2,200 to $1,540 if states fully implement the Medicaid expansion and all of those eligible for Medicaid and the subsidies under the exchange enroll. With full implementation of the ACA, approximately 11.8 million people will no longer have high burden spending—many of whom would be low-income individuals newly enrolled in Medicaid. However, high burden spending would remain a problem for many families, and the variation in the burden of high costs across states would persist. Because most of the reductions in out-of-pocket spending would occur among the low-income population that would be eligible for Medicaid, the impacts of the ACA on high burden spending will be significantly smaller in states that opt out of the Medicaid expansion following the recent Supreme Court ruling that allows for that possibility.

Conclusions: High burden health care spending is a significant issue for residents in every state, affecting more than 56 million Americans nationwide. There is also considerable variation in high burden spending across the states. If fully implemented, the ACA would likely alleviate high burden spending for many individuals, but our estimates suggest that the problem will persist for many families.

Implications for Policy, Delivery, or Practice: The variation across states in high burden spending persists after applying eligibility criteria for ACA provisions addressing affordability. Most of the reductions in out-of-pocket spending burden are among the low-income population that would be eligible for Medicaid, but the impacts of the ACA on high burden spending will be significantly smaller in states that opt out of the Medicaid expansion. It will be important to assess drivers of state level variation in high burden spending after the ACA reforms are implemented to inform future policy solutions. For example, our findings suggest that those with employer based coverage may make up a disproportionate share of individuals who are estimated to continue to have high out-of-pocket cost burdens after the ACA reforms are implemented. Given the uncertainty about how employer coverage and costs will be impacted
by the ACA reforms, it will be important to track high burden spending for this group over time.

**Geographic Variation In Cesarean Delivery In The United States**

Rachel Henke, Truven Health Analytics; Lauren M. Wier, Truven Health Analytics; Richele Benevent, Truven Health Analytics; William D. Marder, Truven Health Analytics; Bernard S. Friedman, Agency for Healthcare Research and Quality; Herbert S. Wong, Agency for Healthcare Research and Quality

**Research Objective:** The primary objective of this study was to determine whether the geographic variation in cesarean section rate is consistent for private insurance and Medicaid. The secondary objective was to identify the patient, population, and market factors associated with cesarean section rate and determine if these factors vary by payers.

**Study Design:** We obtained 2009 hospitalization data from the 44 states that contributed to the Agency for Healthcare Research and Quality Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID) to measure the cesarean section rate at the core based statistical area (CBSA) level. We linked the hospitalization data to data from the U.S. Census Bureau, the Area Resource File, the American Hospital Association, and the National Practitioner Data Bank at the CBSA level to measure population and market characteristics. We calculated unadjusted and risk-adjusted CBSA cesarean delivery rates by payer. We estimated a hierarchical logistical model to determine the factors associated with cesarean delivery.

**Population Studied:** We included all deliveries identified by DRG (370–375) and MS-DRG (765–768; 774–775). We excluded deliveries with the following: any diagnosis of abnormal presentation, preterm birth, fetal death, or multiple gestation diagnosis codes; any breech procedure codes; and previous cesarean delivery diagnosis in any diagnosis field.

**Principal Findings:** Private insurance had a higher primary cesarean rate (18.9 percent) compared to Medicaid (16.4 percent). The correlation between Medicaid and private cesarean rate at the CBSA level was 0.76. The factors predicting cesarean rate were largely consistent across payers, with the following exceptions: under age 18 was associated with a greater likelihood of cesarean section for Medicaid but a greater likelihood of vaginal birth for private insurance; Asian and Native American background were associated with a greater likelihood of cesarean section for private insurance but a greater likelihood of vaginal birth for Medicaid; the percent African American in the population predicted an increased cesarean section rates for private insurance only; the number of acute care beds per capita predicted an increased cesarean section rate for Medicaid only; the number of OB/GYN per capita predicted an increased cesarean section rate for private insurance only, and the number of midwives per capita predicted an increased vaginal birth rate for private insurance only.

**Conclusions:** Differences in cesarean rates for Medicaid compared to private insurance can be partially explained by differing relationships between patient, population and market characteristics and the probability of cesarean section by payer.

**Implications for Policy, Delivery, or Practice:** Understanding the driving forces of geographic variation in frequent and high-resource inpatient procedures, such as cesarean delivery, is key to improving quality of care and reducing healthcare costs.

**Current Health and Insurance Status of Adults Who Will Be Newly Eligible for Medicaid in 2014**

Steven C. Hill, AHRQ; Julie Hudson, AHRQ; Steven C. Hill, AHRQ; Thomas M. Selden, AHRQ; Salam Abdus, Social and Scientific Systems, Inc

**Research Objective:** Describe adults currently eligible but not enrolled in Medicaid and those who will be newly eligible for Medicaid under the Affordable Care Act (ACA).

**Study Design:** Data were from the nationally representative Medical Expenditure Panel Survey (MEPS), which collects detailed information that facilitates simulating Medicaid eligibility: types of income, assets, family structure, and pregnancy. Eligibility under the
ACA was simulated using final federal regulations and assuming all states elect to expand coverage. Multiple Medicaid eligibility categories, such as section 1931 (family coverage), waivers, and medically needy programs were simulated. We used detailed 2005-2009 Medicaid eligibility rules including income eligibility thresholds, income disregards, asset tests, immigration status, the budget units states used for blended families, the processes states used to allocate and deem income in blended families, eligibility of nonparent caretakers and how their income was used in determining eligibility of their parents and siblings. We compared three groups: (1) adults enrolled in Medicaid, excluding those eligible due to disability, (2) adults currently eligible for but not enrolled in eligibility categories states must cover with full benefits, including waiver programs, and (3) adults newly eligible (modified adjust gross incomes not exceeding 138% of poverty), including adults pre-ACA eligible for only limited Medicaid benefits and those eligible for stateoptional programs, such as medically needy. We present point-in-time estimates measured as of the first interview of the second year of the panel. All estimates account for the complex survey design.

**Population Studied:** Adults age 19-64 in MEPS panel 10 through 14, spanning 2005-2009, who were not Medicare beneficiaries and not eligible for Medicaid due to disability. Among them, 2,770 were enrolled in Medicaid, 1,793 were eligible but not enrolled, and 7,221 will be newly eligible.

**Principal Findings:** Our point-in-time estimate is about 23.9 million adults will be newly eligible for Medicaid under the ACA: 14.1 million were uninsured and 8.5 million had employment-related insurance. About 5.0 million adults were eligible for Medicaid under current rules but not enrolled: about 3.0 million were uninsured and about 1.8 million had employment-related insurance. Among those without employment-related insurance, compared with nondisabled Medicaid enrollees, the newly eligible were more likely to live in the South and be older. Compared with nondisabled Medicaid enrollees, the currently eligible but not enrolled adults had better physical and mental health. Both groups were less likely to have any chronic conditions, especially obesity, asthma, and diabetes, than Medicaid enrollees.

**Conclusions:** If all states elect to expand Medicaid, the number of uninsured adults at a point in time could be up to 14.1 million less than in 2005-2009. Both newly eligible and currently eligible but not enrolled adults were healthier than current enrollees.

**Implications for Policy, Delivery, or Practice:** The population currently eligible but not enrolled may be less expensive per capita, because they are less likely to be obese and have diagnosed chronic conditions than current nondisabled Medicaid enrollees, even though this group tends to be older. Anticipated per capita costs of "newly eligible" adults have clear implications on States future Medicaid decisions.

**Poster Session and Number:** C, #1032

**The Politics of Health Insurance Exchanges: Lessons from Idaho and Michigan**

David Jones, University of Michigan School of Public Health

**Presenter:** David Jones, M.A., M.S.P.H., Doctoral Candidate, Health Management and Policy, University of Michigan School of Public Health, davidkj@umich.edu

**Research Objective:** State-based health insurance exchanges are one of the most important elements of the Affordable Care Act (ACA). Understanding the political factors that shaped state decisions to create their own exchange to cede control to the federal government is crucial to evaluating the ACA's success and informing future reform efforts. In the initial months after the ACA was enacted, all but one state began planning for an exchange. By December 2012 only 19 states submitted proposals to create an exchange. Meanwhile, 27 states had sued the federal government over the constitutionality of the law and several states had returned large federal grants in protest. What changed in the 2.5 years after the ACA was enacted that caused less than half the states to create an exchange, particularly in Republican-controlled states?

**Study Design:** Mixed methods, including quantitative analysis of 50 states and two in-depth case studies were employed to examine state decisions to create an exchange as a consequence of partisan control in state government, public opinion, institutional differences such as elected vs. appointed insurance commissioners, roles of interest groups such as the insurance industry and the Tea Party, and heterogeneity in bureaucratic and legislative capacity. The analysis drew on more than 100 interviews with leaders in the
legislative and executive branches at the state and federal levels, as well as relied on publicly available data sources such as opinion polls and government documents.

**Population Studied:** All 50 states are examined, with a particular focus on Idaho and Michigan. Idaho is one of a small number of states led entirely by Republicans that is creating an exchange. Michigan, also led by Republicans, failed narrowly to pass enabling legislation though is pursuing the partnership model.

**Principal Findings:** Despite multiple efforts by the Obama administration to increase flexibility and funding, very few states beyond the initial implementers decided to create an exchange. Partisanship largely drove state decisions; however, the dynamics of why and how are more complex. The extent to which factors such as the growth of the Tea Party and public opinion were significant was contingent upon differences in institutional design. Governors, although the focal point of policymaking, faced multiple constraints in advancing their political agenda.

**Conclusions:** The future of the exchanges will largely be determined by the politics of implementation. The Supreme Court decision and President Obama's re-election ensured the survival of state exchanges. However, success remains uncertain as program funding is being challenged in the courts and in Congress, and because success is eventually determined by the implementation of individual states. Results of the study lay the groundwork for continuing evaluation of state exchange implementation.

**Implications for Policy, Delivery, or Practice:** Future federal reforms need to give more thought to the role of states in implementation. More states may have created an exchange if a clear path not requiring legislation would have been identified at the outset or if states had to commit to a path earlier.

**Conversion to For-Profit Status and its Impact on Access, Quality, and Outcomes in U.S. Hospitals**

Karen Joynt, Harvard School of Public Health; E. John Orav, Harvard School of Public Health; Ashish K. Jha, Harvard School of Public Health

**Presenter:** Karen Joynt, MD, MPH, Instructor, Health Policy and Management, Harvard School of Public Health, kjoynt@partners.org

**Research Objective:** The number of non-profit hospitals converting to for-profit status has accelerated over the past decade, leading many policymakers to worry that after conversion, these hospitals will focus more on improving payer mix and maximizing profits, paying less attention to quality of care or patient outcomes. Therefore, we sought to evaluate what happens to hospitals’ margins, payer mix, quality, and outcomes when they switch from non-profit to for-profit status.

**Study Design:** We used data from Medicare files as well as the American Hospital Association from 2002 through 2010 to identify hospitals that converted to for-profit status and matched them on size, location (based on hospital referral region), and teaching status to similar hospitals that did not convert. For each hospital that converted to for-profit status, as well as for each of the controls, we identified the hospital’s operating margins, and the proportion of each hospital’s patients that were poor (as measured by the Disproportionate Share Hospital or DSH Index). We calculated hospitals performance on Hospital Compare quality metrics as well as mortality rates for common medical conditions. We constructed multivariable difference-in-differences models to compare the year prior to conversion to the year after conversion. We also tested for differences in trend using linear models, looking up to three years after conversion.

**Population Studied:** U.S. acute-care hospitals.

**Principal Findings:** Between 2002 and 2010, there were 216 hospitals that converted to for-profit status. Hospitals that converted to for-profit status had improvements in their operating margins the year following a conversion compared with similar hospitals that did not convert, but this was not statistically significant (-1.1% pre-conversion to 1.6% post-conversion versus -0.2% to 0.5% for controls over the same time period, p=0.36 for difference in differences). Hospitals that converted to for-profit status had comparable change in their proportion of care provided to the poor (DSH Index 28.8% pre-conversion to 26.2% post-conversion, versus 30.3% to 26.8% for controls, p=0.63). We found that hospitals that converted had similar improvements in their composite process scores for acute myocardial infarction (AMI), congestive heart failure (CHF), and pneumonia (PN).
compared to controls (81.5% pre-conversion to 86.6% post-conversion, versus 83.8% to 87.4% for controls, p=0.21). Similarly, there were no differences in changes in mortality rates for AMI (p=0.17), CHF (p=0.80), or PN (p=0.52) at converters compared to controls. Linear models yielded similar results.  

**Conclusions:** We found no evidence that conversion to for-profit status was associated with changes in the proportion of care provided to the poor, or worsening of quality or clinical outcomes.  

**Implications for Policy, Delivery, or Practice:** These findings should provide some reassurance to those concerned that the recent increase in hospitals converting to for-profit status will have deleterious effects on access to care for the poor, the quality of care provided, or clinical outcomes for common medical conditions.

**Young Adults with Private Coverage: Were They Previously Uninsured and Are They Better Off?**

Whitney Kirzinger, National Center for Health Statistics; Robin A. Cohen, National Center for Health Statistics; Renee G. Gindi, National Center for Health Statistics

**Presenter:** Whitney Kirzinger, M.P.H., Health Statistician, Division of Health Interview Statistics, National Center for Health Statistics, wkirzinger@cdc.gov

**Research Objective:** The percentage of young adults aged 19-25 with private health insurance coverage has increased since September 2010, when the Affordable Care Act (ACA) extended dependent health coverage. It may be expected that the observed increase in private coverage is attributable to uninsured young adults obtaining private plans through their parents. However, current national estimates of health insurance coverage do not provide insight into changes in an individual’s coverage type or prior coverage status. The objective of this research is to better understand health coverage among young adults with respect to their previous coverage status, and further explore changes they have experienced since the recent policy change.

**Study Design:** Data were from preliminary Family Core and Sample Adult files of the 2008-June 2012 National Health Interview Survey (NHIS), a cross sectional survey conducted by the National Center for Health Statistics. Data were from retrospective questions about coverage status and opinions about that coverage. Data were combined into six-month periods to maximize precision and reliability of the estimates, while retaining the ability to observe fluctuations over time relative to the implementation of the relevant ACA provision. Measures analyzed included having any period with no health insurance coverage in the past 12 months, current health insurance status, and personal opinion of changes in coverage. While 19-25-year-olds were the focus of this analysis, other age groups were included for comparison.

**Population Studied:** Civilian non-institutionalized residents of the United States aged 19-64.

**Principal Findings:** If young adults moved from uninsured to private coverage after September 2010, we would expect to see a greater percentage of privately insured young adults from Q4 2010 through Q3 2011 saying they had been uninsured in the last year compared with earlier time periods. Once the ACA provision was in effect for one full year, we would expect decreasing or stable percentages of privately insured young adults saying they had been uninsured in the last year. Among privately insured young adults aged 19-25, the percentage with any period of uninsurance in the past 12 months increased from 9.8% to 13.2% in the first half of 2011, decreased to 7.5% in the second half of 2011, and then did not change significantly in the first half of 2012. For comparison, among other age groups, there were no changes in the percentages with any period of uninsurance from 2008 through June 2012. In the last half of 2011, young adults aged 19-25 with private coverage were significantly more likely to say their health care coverage was better or the same compared to one year ago, compared with the first half of 2011.

**Conclusions:** Results provide evidence that newly insured young adults aged 19-25 may have come from the previously uninsured population, and that they perceive their health insurance coverage to be better than or the same as one year ago.

**Implications for Policy, Delivery, or Practice:** This analysis underscores the potential for combining the NHIS’s well-established health insurance information with its data addressing health care reform in order to provide researchers and policymakers a more
Are Distance Based on Addresses Better than ZIP Codes for Assessing Geographic Access to Cancer Care?

May Kuo, University of North Carolina at Chapel Hill; Anne-Marie Meyer, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill; Stephanie B. Wheeler, Health Policy and Management Department, University of North Carolina at Chapel Hill; Brian Frizzelle, Carolina Population Center, University of North Carolina at Chapel Hill; Marc Peterson, Carolina Population Center, University of North Carolina at Chapel Hill; William Carpenter, IV, Health Policy and Management Department, University of North Carolina at Chapel Hill

Presenter: May Kuo, PhD, Research Associate, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, tkuo@email.unc.edu

Research Objective: Distance is used as a proxy measure for geographic access to healthcare, but measures of distance vary in their precision according to the granularity of the data and methods of calculation. Methodological differences in estimating distance may partially explain the inconsistent relationships observed in the literature between distance and healthcare access. Although studies exist on the correlations between different distance metrics, the impact of different distance measures on healthcare access has not been directly examined. In this study, we examined the impact of distance on receipt of radiation therapy (RT) after breast cancer surgery using different methods (e.g., straight line and Network distance) and with different levels of measure granularity (e.g., address and ZIP code centroids).

Study Design: A retrospective cohort was created from women diagnosed with breast cancer and reported to the North Carolina Central Cancer Registry in 2003-2005. Women who were eligible for RT were identified by linking registry data to Medicare insurance claims and using diagnostic and procedural codes (e.g., CPT/HCPCS and ICD 9). Physicians providing RT were also identified from the claims and relevant address information was abstracted from the Medicare Physician Identification and Eligibility Records. Patients’ address information was obtained from the NC registry. Both the addresses and ZIP code centroids from patients and physicians were geocoded using ESRI ArcGIS. We computed Euclidean distance using SAS GEODSIT function and network distance using ArcGIS. Logistic regression models were used to examine the probability of treatment receipt associated with distance to nearest provider. Models were adjusted for patient demographics, tumor characteristics, other treatment, and a measure of patient’s county as urban or rural. We compared models using the following distance measures: Euclidean distance from address, Euclidean distance from ZIP code centroid, network distance from address, and network distance from ZIP code centroids. Effect of distance metric was obtained by comparing the model-predicted probability of radiation therapy receipt for each distance measure.

Population Studied: We identified 1,938 Medicare-insured women who were eligible for RT in our registry-linked claims cohort. Sixty-five percent of the study sample received RT, and the mean age was 74 years. The majority of the women were white, diagnosed at an early stage, and living in urban areas.

Principal Findings: There was no difference in the mean Euclidean distance using addresses vs. ZIP codes. However, longer network distances were obtained from ZIP codes compared to addresses. Results from regression models suggested that distance is negatively related to receipt of radiation treatment. Moreover, the magnitude of the effect appeared to be influenced by the type of distance measure, granularity of the data used for computing distance and urban vs. rural areas.

Conclusions: When Euclidean distance is used, addresses and ZIP codes are equally well in predicting cancer care; however, when network distance is used, results from addresses and ZIP codes may differ.

Implications for Policy, Delivery, or Practice: Our study provides valuable information for researchers who are interested in using distances to evaluate geographic access to healthcare. This is increasingly important to health services research where actual address data are increasingly difficult to obtain.

Coverage Alternatives for Poor Adults in States without a Medicaid Expansion
Rachel Licata, Kaiser Family Foundation; Vann Newkirk, MSPH, Kaiser Family Foundation; Anthony Damico, MHS, Kaiser Family Foundation

Presenter: Rachel Licata, M.P.H., Senior Policy Analyst, Kaiser Family Foundation, rachell@kff.org

Research Objective: Two central goals of the 2010 Affordable Care Act (ACA) are reducing the number of uninsured and increasing the affordability of coverage. One mechanism to accomplish this is the expansion of Medicaid to almost all individuals with incomes below 138% of poverty. The June 2012 Supreme Court decision made this expansion optional for states, and as of December 2012, nine states have indicated that they do not plan to expand Medicaid. Adults with family incomes over 100% of poverty can still receive subsidies for insurance coverage through the Exchange in non-expansion states, but those with incomes below poverty may be left without any ACA coverage options. This analysis assesses current and future insurance options for adults living with incomes below poverty in the context of the ACA provisions and Supreme Court decision.

Study Design: We analyzed data from the April-July 2010 Survey of Income and Program Participation (SIPP). We examined current health insurance coverage (uninsured, Medicaid, other public, private non-group, or employer-sponsored insurance (ESI)) as well as work status and firm characteristics. We also assessed ESI offer rate and eligibility using variables unique to SIPP. We determined income and eligibility using constructed health insurance units (HIUs), which group individuals based on their eligibility for subsidies in the Exchange, rather than by household or relatedness. This approach allowed us to classify adults by their eligibility for exchange subsidies under the ACA, thus determining more precisely who might not receive assistance if Medicaid is not available.

Population Studied: Analysis was limited to non-elderly adults ages 19-64, who were not enrolled in Medicare and had an HIU income of less than 100% of poverty ($22,050 for a family of four in 2010).

Principal Findings: Among poor adults, forty-eight percent were uninsured, 20 percent had ESI and 23 percent were enrolled in Medicaid. Most adults in this income range are not working or do not have a worker in the family. However, even among poor adults who are working, only 32 percent received an ESI offer, as most poor workers are employed by small firms and 66 percent work part-time. Among the poor workers who are offered coverage, most decline due unaffordability of coverage.

Conclusions: The Medicaid expansion could cover nearly all adults below poverty in expansion states, but in states that do not expand Medicaid, many poor adults are likely to go without coverage. Several key aspects of the ACA, including the creation of the Exchanges and incentives to offer ESI, will not provide insurance options to most poor adults. Many may continue to remain uninsured or may lose current insurance with the expiration of the Medicaid Maintenance of Eligibility.

Implications for Policy, Delivery, or Practice: The Medicaid expansion is a crucial component of the ACA goal of reducing the number of uninsured. Without this expansion, many poor adults are likely to go without coverage. Given the impact of the uninsured on uncompensated care costs and safety net providers, states should consider the consequences of not expanding their programs.

Protecting Vulnerable Families from Losing Coverage
Kristen Lloyd, Rutgers; Dorothy Gaboda, Rutgers Center for State Health Policy; Jose Nova, Rutgers Center for State Health Policy

Presenter: Kristen Lloyd, Research Analyst, Rutgers, klloyd@ifh.rutgers.edu

Research Objective: Continuity of health insurance coverage is important for achieving optimal utilization of medical care. The Affordable Care Act expands insurance coverage, but previous research indicates possible risks to maintaining seamless coverage for families whose eligibility for public coverage, employer-sponsored coverage, and Exchange-based coverage is likely to fluctuate over time. As a gateway state, a higher proportion of New Jersey families will have to contend with eligibility and enrollment issues stemming from immigration status in addition to changes in life
and/or economic circumstances which put them at risk for eligibility disruptions. These families often face administrative and logistical complexity in accessing health coverage and care. Therefore, it is important states understand the characteristics of families who are vulnerable to churning in order to develop strategies for maintaining continuous coverage.

**Study Design:** Cross-sectional data from the 2009 New Jersey Family Health Survey are analyzed to identify working-age parents who are at risk for churning. Bivariate and multivariate analyses are used to identify the numbers and characteristics of vulnerable parents.

**Population Studied:** New Jersey community-dwelling working-age parents of children under age 19 who are eligible for public or subsidized Exchange coverage.

**Principal Findings:** Parents vulnerable to changes in coverage eligibility are more likely younger, in single-parent families, have lower family incomes, and less likely to be working. They have worse self-rated health, lower levels of utilization, and are less likely to have a usual source of care than parents not at risk for churning. They also express attitudes indicating a weak attachment to health insurance as a mechanism for managing their health care. Among parents at risk for churning, non-access-dependent indicators of health are worse among immigrant adults even though they are socioeconomically comparable to native-born adults and no less likely to have visited a doctor or have a usual source of care. Immigrant parents are more likely to be Hispanic and to express attitudes indicating a weak attachment to health insurance.

**Conclusions:** Immigrant parents in New Jersey, and their children by extension, are particularly vulnerable to churning and the health consequences of disrupted coverage. Parents with a weak attachment to health insurance are likely to require targeted support to maintain enrollment in health coverage.

**Implications for Policy, Delivery, or Practice:** States with large immigrant populations have additional considerations in planning their health insurance outreach and enrollment systems to assist vulnerable adults and their families in maintaining health coverage. Strategies to synchronize family coverage, to incentivize insurance plans to participate in all Exchange programs, to engage parents when they experience life changes affecting eligibility, and to ensure the cultural and linguistic sensitivity of all efforts targeting immigrants are important for promoting seamless coverage. Moreover, assurance of the consistency of health coverage can help foster confidence in the health insurance system as a preferred mechanism for managing health care, thereby enhancing the effectiveness of efforts to keep vulnerable families enrolled.

**Risky Business – The Transition of High Risk Pool Enrollees to Other Coverage in 2014**

Lynn Blewett, State Health Access Data Assistance Center (SHADAC), University of Minnesota; Elizabeth Lukanen, University of Minnesota; Kathleen Call, State Health Access Data Assistance Center (SHADAC), University of Minnesota; Heather Dahlen, State Health Access Data Assistance Center (SHADAC), University of Minnesota; Karen Turner, State Health Access Data Assistance Center (SHADAC), University of Minnesota

**Presenter:** Elizabeth Lukanen, M.P.H., Senior Research Fellow, State Health Access Reform Evaluation, University of Minnesota, elukanen@umn.edu

**Research Objective:** For millions of Americans with preexisting health conditions, affordable health insurance is only a dream. These individuals often seek coverage, but are either unable to afford the premium, unwilling to settle for coverage with condition exclusions or are rejected outright. The Affordable Care Act (ACA) provided $5 billion dollars to develop high risk pools in all states. This temporary measure was designed as a bridge to cover people until the more sweeping “guarantee issue” provision went into effect in 2014. More than 95,000 individuals are currently covered through the federal Pre-Existing Condition Insurance Plan (PCIP) and more than 220,000 are covered by state-only pools. It is generally assumed that the majority of these high risk pool enrollees will gain coverage through the exchange once it is in place. It is unclear, however, how smooth this transition will be, where these individuals will ultimately seek and gain coverage, and what impact this transition will have on Medicaid, the exchange and the affected individuals. This paper seeks to answer these questions by studying the longest running and largest high risk pool in the country – The Minnesota Comprehensive Health Association (MCHA).
**Study Design:** Mail survey of 4,800 randomly selected MCHA enrollees with a low-income over-sample, conducted from November through December, 2012. 63% response rate weighted to reflect general characteristics of the enrolled population. Survey collects descriptive data on characteristics of the MCHA enrollees including potential eligibility for Medicaid or exchange subsidies (post-2014), current health and disability status, health care use and demographics, enrollee coverage priorities, knowledge of the ACA, and preference for outreach enrollment information.

**Population Studied:** Enrollees from the largest and longest running risk pool in the county – the Minnesota Comprehensive Health Association.

**Principal Findings:** Preliminary analysis (using unweighted data) indicates that more than three quarters of the population reports fair or poor health, a quarter had four hospital visits in the last year and 85% had multiple trips to the ER. Income data indicates that a large proportion of the enrollees may be eligible for Medicaid post-2014. In addition, the vast majority have only a high school education and have fairly poor awareness of the ACA and the new coverage options that will be available.

**Conclusions:** States and the federal government must be prepared to transition high risk pool enrollees in 2014. This study indicates that enrollees will likely end up in both the exchange and Medicaid. They are likely to be sicker than the general population and have relatively low awareness that these changes are coming.

**Implications for Policy, Delivery, or Practice:** It has long been assumed that high risk pool enrollees would simply transition into Medicaid or the exchange in 2014. By examining Minnesota’s high risk pool enrollees, states and the federal government can get a sense for where these individuals might transition, how this might impact existing risk pools, how smooth the transition will be and how best to communicate and provide outreach to these enrollees.

**Impact of Primary Care Availability on Hospital Inpatient Use by Insurance Status**

Jared Lane Maeda, Kaiser Permanente; Rachel Mosher Henke, PhD, Truven Health Analytics; Emily Ehrlich, MPH, Truven Health Analytics; William D. Marder, PhD, Truven Health Analytics; Bernard S. Friedman, PhD, Agency for Healthcare Research and Quality; Herbert S. Wong, PhD, Agency for Healthcare Research and Quality

**Presenters:** Jared Lane Maeda, Ph.D., M.P.H., Research Scientist, Kaiser Permanente Research Institute, Kaiser Permanente, jared.l.maeda@kp.org

**Research Objective:** Reducing avoidable hospitalizations is a major target of recent health care reform efforts. Increasing the supply of primary care providers has been proposed as one way to reduce hospitalizations because primary care emphasizes prevention, detection, and early treatment. However, there is little empirical evidence that has linked increased availability of primary care to reduced hospitalizations. Further, it is unknown if primary care availability has the same effect on hospitalization rates for the uninsured as the insured. The uninsured may still have financial, cultural, and/or logistical barriers towards accessing primary care despite efforts to enhance primary care availability. The purpose of this study is to examine the association between primary care availability, all-cause hospitalizations, and admissions for three common types among nonelderly adults (ambulatory care sensitive conditions, mental health and substance abuse, and mandatory admissions). We also examine whether the association between primary care availability and hospital use holds for the uninsured.

**Study Design:** We examined variations in inpatient hospitalizations between the insured and uninsured across Core Based Statistical Areas (CBSAs) in 44 states. We also explored the association between primary care availability and hospital use by insurance status while controlling for patient, population and market factors using a broad definition of primary care. Poisson regression models were used to estimate the relationship between primary care availability and the rate of hospitalizations by insurance status.

**Population Studied:** We used the 2009 Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID) from 44 states. The SID were linked with the Area Resource File, American Hospital Association Annual Survey, and U.S. Census Bureau data files. We included all discharges in CBSAs where the patient was between 18 to 64 years old.

**Principal Findings:** Primary care supply is generally linked to lower hospitalizations across
Department visits increased in MA, but which services and by how much are unknown. The objectives of this study were to examine the effects of health care reform on inpatient services and emergency department visits in MA.

**Research Objective:** The Commonwealth of Massachusetts implemented the first phase of a broad health care reform program from 2006 through 2008. This reform is widely viewed as the model for the Patient Protection and Affordable Care Act (ACA). The Massachusetts (MA) reform has increased insurance coverage and improved access to care. How the ACA will affect the hospital sector is undefined. Covering the uninsured will increase demand for health care services, but which services and by how much are unknown. The objectives of this study were to examine the effects of health care reform on inpatient services and emergency department visits in MA.

**Study Design:** We used data from the Agency for Healthcare Research and Quality Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID) and the State Emergency Department Databases (SEDD). We implemented a difference-in-difference model to estimate the impact of the legislation and examined the changes between 2005 and 2009 in both MA and control hospitals for a limited number of high-level indicators: discharges (overall and in selected categories); length of stay; cost per discharge; and emergency department (ED) visits and charges. We also examined trends in inpatient admissions for acute and chronic ambulatory care sensitive conditions. We also estimated regression models that controlled for the hospital's competitive environment for both the inpatient and ED variables.

**Population Studied:** We examined hospitals in states that provided data both during a calendar year prior to the MA reform (2005) and the second full year after implementation (2009): 37 and 24 states in the SID and SEDD, respectively. There were 64 MA hospitals with nonmissing values for all of the variables used in this study (62 with EDs). The control populations were propensity-score matched samples of hospitals drawn separately from the SID and the SEDD. We matched on 2005 characteristics of the institutions, including the volume of services delivered and the demographic characteristics of the patients. Given the greater number of states reporting in the SID, we were able to match 5 control hospitals in other states for each MA hospital for the inpatient analyses and 3 EDs outside MA for each ED within the state.

**Principal Findings:** Changes in inpatient utilization in MA were similar to those in other states. Length of stay declined more rapidly relative to the control sample (−6.0% versus −0.4%, respectively. The number of preventable hospitalizations for acute conditions declined in MA and the rest of the country. Hospitalizations associated with chronic conditions increased overall; results are at least suggestive that they rose faster in MA (0.05 < p < 0.10). ED utilization grew in both groups, but ED charges per visit grew more slowly over the 5-year period in MA (36.4% compared to 60.7% in the matched control hospitals).

**Conclusions:** Overall, the Massachusetts reform had modest effects on the hospital sector.

**Implications for Policy, Delivery, or Practice:** The results of this study are of direct policy relevance.

**Impact of Massachusetts Health Care Reform on Insurance Coverage, Access to and Receipt of Care and Health Status among Patients with Cardiovascular Disease or Risk Factors**

Danny McCormick, Harvard Medical School / Cambridge Health Alliance; Amresh Hanchate, VA Boston Healthcare System, Boston, MA; Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; Mengyun Lin, Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; Karen E. Lasser, Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; Meredith D’Amore, Section of General Internal Medicine, Boston University School of Medicine, Boston, MA; Nancy Kressin, VA Boston Healthcare System, Boston, MA; Section of General Internal Medicine, Boston University School of Medicine, Boston, MA

**Presenter:** Danny McCormick, M.D., M.P.H., Assistant Professor, Harvard Medical School / Cambridge Health Alliance, danny_mccormick@hms.harvard.edu

**Research Objective:** Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in the US, and racial and ethnic disparities in CVD prevalence and treatment disproportionately shorten life expectancy for minorities. We sought to determine the impact of the Massachusetts (MA) health care reform, the model for US national health care reform, on coverage, access to care and health status among patients with known CVD or cardiovascular risk factors (CVRF) and racial disparities in these outcomes.

**Study Design:** We estimated pre- to post-reform absolute differences (AD) and 95% confidence intervals in MA in the proportion of individuals having insurance coverage, access to care, utilization of care and good/excellent health status using a difference-in-differences approach that accounted for secular trends in control states and patient demographic characteristics using linear probability models. We also examined changes in racial and ethnic disparities in these outcomes following reform.

**Population Studied:** We analyzed data from the Behavioral Risk Factor Surveillance System (BRFSS), representative statewide cross-sectional adult surveys from MA and seven control states that did not undergo health reform (RI, VT, NH, CT, NY, NJ and PA), before (2005) and after (2009) MA health reform implementation. The survey sample (n=6,698 in MA, and 28,455 in control states) consisted of adults age 18-64 (those targeted by the reform) who reported having CVD (history of myocardial infarction or stroke) or 2 or more CVRFs (current cigarette smoking, hypertension, hyperlipidemia, obesity [BMI>30] and age>50 for men and >55 for women).

**Principal Findings:** We found increases in the proportion of MA respondents reporting having insurance (89.9 to 94.7%; adjusted AD (aAD), 4.2% [2.2, 6.2]), a personal doctor (90.6 to 94.2%; aAD, 2.2; [0.37, 4.0]) and no financial barriers to seeing a doctor (89.1 to 91.4%; aAD, 3.8 [1.6, 6.0]). We found no statistically significant changes in the proportion reporting a routine check up in the last year (79.9 to 83.4%; aAD, -0.7% [-2.8, 2.6]), taking a blood pressure medication among patients with hypertension (69.5 to 73.3%; aAD, 0.7%; [-2.8, 4.2]), taking a lipid lowering medication among patients with hyperlipidemia (85.2 to 87.2; aAD; 0.35 [-2.6, 3.3]), having excellent/good health (80.0 to 79.8%; aAD, -1.6 [-4.3, 1.0]), having no activity limitations due to health (75.0 to 73.7%, aAD, 2.0 [-0.8, 4.8]) and not currently smoking cigarettes (46.1 to 42.3, aAD, -2.5 [1.3, -6.3]). There were no statistically significant changes or consistent trends in black-white or Hispanic-white disparities in insurance coverage (aAD, -4.0 [-13.2, 5.1] and 4.4 [-2.9, 11.7], respectively) or having no financial barriers to seeing a doctor (aAD, 2.7 [-5.3, 10.7] and -4.3 [-15.4, 6.7], respectively).

**Conclusions:** For patients with known CVD or CVRFs, MA health reform was associated with modest to small improvements in insurance coverage and access to care but no improvement in receipt of care or health status or in racial and ethnic disparities in coverage or access.

**Implications for Policy, Delivery, or Practice:** Additional health care reform measures may be required to more substantially improve these outcomes for patients who are at high risk for or have CVD.

Assessing Pent-Up Demand in California’s Uninsured Population

Dylan H. Roby, PhD, UCLA Center for Health Policy Research; Dimiter Milev, UCLA Fielding School of Public Health; Xiao Chen, PhD, UCLA Center for Health Policy Research; Christina M. Kinane, MPA, University of Michigan, Department of Political Science; Julia T. Caldwell, MPH, UCLA Fielding School of Public Health, Department of Health Policy and Management; Erin Salce, MPH, UCLA Center for Health Policy Research

Presenter: Dimiter Milev, Research Assistant, Department of Health Policy and Management, UCLA Fielding School of Public Health, dimilev@ucla.edu

Research Objective: Explore potential changes in healthcare use and demand for services by quantifying the healthcare needs of uninsured adults gaining access to new coverage options via Medicaid expansion and Health Insurance Exchanges due to the Affordable Care Act.

Study Design: Using data from California’s 2007-2010 Medicaid waiver, we followed enrollees’ transition from being uninsured to insured and the effects of demographic and geographic characteristics on utilization over a maximum of four years. To estimate expected levels and rates of increase in use across uninsured and safety net user populations, we performed a two-part analysis with binomial logit and Poisson-logit hurdle regression models. Estimates of primary care, inpatient, emergency room, and specialty services use for different categories of newly insured adults are based upon utilization data prior to and after enrollment in California’s Health Care Coverage Initiatives (HCCI). We then applied the HCCI-based models to 2009 California Health Interview Survey data on the uninsured.

Population Studied: Non-Elderly (18-64 year old) Medicaid and Exchange beneficiaries eligible to enroll in ACA coverage options in 2014. The HCCI population is made up of authorized California residents or citizens who will qualify for Medicaid or Exchange subsidies in 2014.

Principal Findings: Predicted primary care service use proportions remained stable even after obtaining new coverage, increasing by 3% from year 1 to year 3 (42.2% to 43.3%) among non-users of indigent care prior to HCCI program enrollment and 1% (59.1% to 59.4%) among existing users.

Temporary predicted increases in use of inpatient, emergency room and specialty care services stabilize in subsequent years. A slightly larger proportion of non-users (22.7%) utilize ER services in year 1 than their existing user counterparts (21.2%), but users only exhibit a 2.1% decrease in ER use by year 2 while non-users exhibit a decrease of 9.5%.

Specialty care use in the first year of enrollment is substantially lower for non-users (15.1%) than existing users (24.8%). Though use proportions were stable over time, actual numbers of visits per year exhibit a leveling out of pent-up demand with year 1 to year 3 decreasing from 0.9 to 0.43 visits per year (52%) among users and 0.54 to 0.29 (46%) among non-users.

Conclusions: The general stability in predicted services utilization suggests concern about pent-up demand among future Medicaid or Exchange eligibles may be unfounded. In California, approximately 500,000 people likely to enter Medicaid and the Exchange via transition from county Low-Income Health Programs have been provided with significant care and appear to have stable health services use.

Implications for Policy, Delivery, or Practice: Analysis informs California’s planning for the expansion of Medi-Cal and the Covered California Exchange. Actionable estimates of pent-up demand enable pragmatic workforce and facility planning by informing necessary primary care and specialty care staffing levels and supply. Estimates also facilitate Exchange implementation by helping understand use patterns of the enrolled population and assessing the sustainability of the risk pool in the Exchange. Lastly, estimates allow leadership to prepare for new enrollees into Medi-Cal through evidence-based estimates of predicted use.

Thirty Day Readmission and the Use of Follow-up Care among Non- Elderly Adult Medicaid Enrollees

Chima Ndumele, Brown University; Vincent Mor, PhD, Brown University; Susan Allen, PhD, Brown University; James F Burgess, PhD, Boston University; Amal N Trivedi, MD MPH, Brown University

Presenter: Chima Ndumele, M.P.H., Student, Department of Community Health, Brown University, chima_ndumele@brown.edu
Research Objective: Unplanned 30-day readmissions to hospitals are a growing concern for the Centers for Medicare & Medicaid Services (CMS). While rates and determinants of readmissions have been studied extensively in the Medicare population, little is known about the burden of readmissions among Medicaid enrollees. We calculated the rates of 30-day readmissions for non-elderly adult Medicaid enrollees and examined whether rates are mediated by the use of outpatient care in the period following discharge.

Study Design: We used multivariable logistic regression to examine the prevalence of 30-day all cause readmissions following hospitalization for congestive heart failure (CHF), acute myocardial infarction (AMI), or pneumonia among a sample of Medicaid managed care enrollees. Models accounted for demographic and clinical characteristics of enrollees and used generalized estimating equations to account for repeat observations from enrollees over time and enrollees discharged from the same hospital. The primary independent variable was the use and source of follow-up care in the 7 days following discharge (no care, primary care physician only, cardiologist and primary care physician).

Principal Findings: Of 2,331 discharges, 616 (26%) resulted in a readmission to the hospital within 30 days. Within specific diagnoses, readmission rates ranged from 23% for AMI to 32% for CHF. 36% of enrollees were readmitted within 7 days of discharge. Among enrollees discharged with cardiovascular conditions (CHF/AMI), approximately 8% received follow-up care from a cardiologist within 7 days of discharge, 41% received follow-up care from a primary care physician only, and 51% did not receive follow up care at all. Among enrollees hospitalized with pneumonia, 45% did not receive follow up care in the 7 days following discharge. After adjustment for demographic and clinical characteristics, enrollees with cardiovascular conditions who sought care from a PCP and specialist had 0.56 the odds of 30-day readmission relative to enrollees who did not seek follow up care (95% CI 0.33, 0.78). Enrollees receiving follow up care from a primary care physician alone had 0.83 the odds of 30-day readmission relative to enrollees who did not seek follow up care (95% CI 0.64, 1.04). There were no significant differences in the odds of 30-day readmissions between enrollees discharged with pneumonia based on their receipt of follow up care (p = .78). Results were qualitatively similar when limited to one discharge per enrollee.

Conclusions: All-cause readmissions occur with striking frequency in the adult Medicaid population and a considerable proportion of these readmissions occur within 7 days of discharge. Approximately half of Medicaid enrollees do not receive any care in the period following discharge and few have access to specialty care. For enrollees discharged after severe cardiovascular events, accessing both primary and specialty care is associated with the lowest odds of readmission.

Implications for Policy, Delivery, or Practice: Access to primary and specialty care may mediate the risk of readmission among Medicaid enrollees. State Medicaid programs should consider improving continuity of care to reduce unplanned readmission rates among non-elderly Medicaid enrollees.

Understanding the Impact of the Affordable Care Act on Health Insurance and Medical Care Utilization among Young Adults Aged 19-25

Helen Parsons, University of Texas Health Science Center at San Antonio; Susanne Schmidt, MA, University of Texas Health Science Center

Presenter: Helen Parsons, Ph.D., M.P.H., Assistant Professor, University of Texas Health Science Center at San Antonio, parsonsh@uthscsa.edu

Research Objective: The Affordable Care Act (ACA) extended dependent healthcare coverage up to the age of 26, allowing young adults to stay on their parents’ or relatives’ insurance longer. This research examines trends in insurance coverage in the young adult (aged 19-25) population before and after the policy took effect for plan renewals beginning in September 2010. Further, it examines the role that changes in insurance coverage have played in the use of preventative and emergency medical care over time.

Study Design: We used the 2008-2011 National Health Interview Survey (NHIS) to examine trends in insurance over time. Logistic regression models adjusted for survey design...
were then computed to estimate the effect of time, health insurance, demographic, socioeconomic, and health characteristics on 1) receipt of a flu shot, 2) doctor visit, 3) dentist visit and 4) emergency room visit in the past 12 months.

**Population Studied:** Young adults aged 19 to 25 (n=11,669) who participated in the 2008-2011 NHIS.

**Principal Findings:** Insurance rates increased significantly among young adults from 2008 to 2011. While rates of insurance were decreasing from the first quarter of 2008 (70.8% insured) until the third quarter of 2010 (64.5% insured) when the ACA expansion went into effect, rates have steadily increased since the expansion of dependent coverage (64.5%; Q3 2010 to 74.1%; Q4 2011). However, in 2011, only a small proportion (1.0%) of individuals reported receiving insurance coverage through their parents/relatives, while the majority of those with private insurance received benefits through their workplace (86.5%). Multivariate regression demonstrated that young adults were more likely to receive a flu shot (OR [95% CI]: 1.70 [1.41-2.06]) and visit the dentist (OR [95% CI]: 1.20 [1.04-1.38]) over time after adjusting for individuals’ demographic, socioeconomic and health characteristics. However, we saw no increase in the likelihood of visiting a doctor (OR [95% CI]: 1.05 [0.90-1.22]) or the emergency room (OR [95% CI]: 1.05 [0.90-1.22]) over time. Further, despite the increases in insurance coverage over time, uninsured young adults continue to be less likely to receive a flu shot, visit the dentist, or visit the doctor after accounting for survey year (p<0.05 for all). Interestingly, no significant differences remain between privately insured and uninsured individuals in use of ER care after accounting for survey year and other demographic, socioeconomic, and health characteristics.

**Conclusions:** While insurance rates have increased for 19-25 year old young adults since the implementation of expanded dependent coverage under the ACA, insurance rates are still low. However, the proportion of young adults receiving insurance through their parent/relative was minimal in 2011. Further, as insurance rates increased, the likelihood that young adults would utilize preventative healthcare (i.e., flu shot, dentist visit) also increased, while use of emergency care remained stable.

**Implications for Policy, Delivery, or Practice:** Our research contributes to knowledge of the early implications of the ACA on insurance coverage and healthcare utilization among young adults in the US, demonstrating that while insurance rates are increasing, few young adults obtained coverage through their parent/relative in 2011. Future research should examine knowledge of and barriers to dependent coverage under the ACA.

**Healthcare Reform: Closing the Health Disparities Gap. Where does Patient Navigation Belong?**

Michael Preston, University of Arkansas for Medical Sciences; Katherine Glover-Collins, MD, PhD, University of Arkansas for Medical Sciences; Dale E. Gray, BS, University of Arkansas for Medical Sciences; Sharla A. Smith, MPH, University of Arkansas for Medical Sciences; Ronda S. Henry-Tillman, MD, FACS, University of Arkansas for Medical Sciences

**Presenter:** Michael Preston, M.P.H., Ph.d.c, Director, Cancer Control, University of Arkansas for Medical Sciences, mapreston@uams.edu

**Research Objective:** Prostate cancer is the most commonly diagnosed cancer and second leading cause of cancer death in the US among men. Although overall incidence and mortality has decreased over time, disparities still exist among racial/ethnic groups. Strategies to reduce disparities in cancer detection, treatment, and outcomes among racial/ethnic minorities and low-income patients have been gathering momentum with the introduction of patient navigation (PN) initiatives. The current advancement of medical knowledge and technology spurs a widening gap in healthcare delivery for racial/ethnic minorities and medically underserved populations for certain emerging state-of-the-art treatments. The controversy around the effectiveness of prostate-specific antigen (PSA) and digital rectal exam (DRE) as screening tools was cited as a possible reason for this information void, but research suggests that African American males rely on their physicians to recommend all needed tests/screenings. The study examined the current and potential roles of PN in the improvement of prostate cancer screenings among disadvantaged populations.

**Study Design:** A Longitudinal study design was conducted on males over 35 years of age to examine the role of patient navigation on equity of access to prostate cancer screening among
disadvantaged populations since 2008 (n=1602). Patient’s demographics, geographical location, PSA scores, and DRE scores, and the array of event types in which community engagement occurred were collected. Data were analyzed using comparison analyses.

**Population Studied:** Males over 35 years of age from disadvantaged populations since 2008.

**Principal Findings:** Patient navigation allowed for greater utilization of health services among populations of rural origins (Urban: n=747; Rural: n=833). Mean PSA scores were within normal range, although mean PSA scores for non-whites residing in rural areas (1.45ng/mL) was slightly higher than non-whites in urban areas of the state (1.36ng/mL; p=0.03). The mean age was 54 years (Urban: 51 years; Rural: 56 years; p=0.001).

**Conclusions:** Equity of access to cancer screenings among disadvantaged populations may be achieved with the utilization of patient navigation programs. Access to the health care system is a strong barrier which fosters disparities among disadvantaged populations.

**Implications for Policy, Delivery, or Practice:** PN allows rural disadvantaged populations entry into the health care system at earlier stages, considering PSA as a proxy for disease. Health care reform lays the foundation for preventative programs such as patient navigation.

**Defining Service Areas for Federally-Funded Community Health Centers in the United States**

Jennifer Rankin, Robert Graham Center of the American Academy of Family Physicians; Carolyn Fahey, Robert Graham Center of the American Academy of Family Physicians; Andrew Bazemore, Robert Graham Center of the American Academy of Family Physicians

**Presenter:** Jennifer Rankin, Ph.D., Geospatial Informatics Senior Analyst, Robert Graham Center of the American Academy of Family Physicians, jrankin@aafp.org

**Research Objective:** To construct individual Community Health Center Service Areas (CHCSAs) based on 2011 utilization data that permit the better identification of areas and populations unserved by health centers.

**Study Design:** Secondary data analysis using a modified Griffith Commitment Index, data from the 2011 Uniform Data System were used to create service areas based on where the most patients live who come to each health center (Actual service areas or CHCSAs). CHCSAs were compared to the service areas that were funded (funded service areas) for each health center and service area demographics were compared.

**Population Studied:** United States Federally Funded Community Health Centers. Patient data were aggregated by ZIP Code by the reporting entity and converted to counts by ZIP Code Tabulation Area (ZCTA). ZCTAs with fewer than 11 patients were excluded from the data provided.

**Principal Findings:** Funded service areas and CHCSAs are quite different, with actual CHCSAs being larger, on average, than the areas that health centers are funded to serve. While the areas differ, population demographics within the areas are strikingly similar.

**Conclusions:** CHCSAs allow planners and policy makers to better understand gaps and overlaps in the safety net. Assessing unmet need in areas of perceived overlapping service, and potential population disparities, may avoid assumption pitfalls and identify populations needing targeted services.

**Implications for Policy, Delivery, or Practice:** This is the first step to understanding funded versus actual service areas. Federally-funded community health centers receive funding to provide primary medical, dental, and behavioral health services to underserved communities. Despite best efforts to prevent federal funding of multiple health centers serving the same geographies, service areas often overlap. Current “overlap” discussions are based on funded service areas rather than actual service areas. Furthermore, it is inappropriate to assume that because an area is being served by one or more health centers that the population is well served. Understanding the actual service area of federally funded community health centers is essential to planners hoping to evaluate access for underserved populations and for identifying areas where the need for federal resources remains.

**Comparing Primary Care Service Areas to Estimated Drive Times: An Evaluation of Geographic Accessibility to Primary Health Care**

Jennifer Rankin, American Academy of Family Physicians; Sean Finnegan, American Academy
of Family Physicians; Dr. Nigel Waters, George Mason University; Dr. Kevin Curtin, George Mason University; Dr. Timothy Leslie, George Mason University

Presenter: Jennifer Rankin, Director, Robert Graham Center, American Academy of Family Physicians, jrankin@aafp.org

Research Objective: Healthcare service areas allow for the measurement of health outcomes, assessment of health care services utilization and healthcare shortage area designation that are at the center of policy decisions. Generally these services areas are created out of predefined census geographies, but some policy decisions are made based on geographic accessibility in regards to the distance, or travel time to healthcare providers.

Study Design: This research evaluates the geographic accessibility of populations in rural areas of Missouri, Oregon and North Carolina to primary care physicians within Primary Care Service Areas (PCSAs). This is accomplished by comparing PCSAs to 30-minute drive-time polygons calculated in ArcMap centered on primary care physician locations. Population from the 2010 Census at the block level was used to calculate the coverage of the PCSA and the estimated drive-times. A quantitative comparison was made based on the difference in area and population coverage by each corresponding drive-time and PCSA and the percent of population that was included in each PCSA, but outside of an estimated 30-minute drive time.

Population Studied: The study focused on areas and populations that are within PCSAs of North Carolina, Missouri and Oregon that were classified as small rural, or isolated, according to the Rural Urban Commuting Codes and that contained a single primary care provider as listed in the National Plan and Provider Enumeration System.

Principal Findings: 72 percent of the PCSAs in the sample contained people that live outside of the 30-minute estimated drive-time polygon accounting for 14 percent of the total population living in the sample PCSAs. When considering the PCSAs that had the most people living outside the 30-minute drive-time polygon, 42.4 percent of the population lived outside of that drive-time polygon.

Conclusions: The utilization of estimated drive, or travel, times is an effective addition to the creation process for PCSAs and the evaluation of geographic access to primary health care, utilization and health outcomes. Some PCSAs in the study areas should be reconsidered with these travel time considerations for more effective policy decisions.

Implications for Policy, Delivery, or Practice: Health care service areas, such as Primary Care Service Areas, should consider travel time, or travel distance, such as estimated drive times along road networks as they are a realistic measure of who can access health care services.

Access to Primary Care on the Eve of ACA Implementation
Karin Rhodes, University of Pennsylvania, School of Medicine; Genevieve Kenney, The Urban Institute; Ari B Friedman, University of Pennsylvania; Doug Wissoker, The Urban Institute; David Chearo, The University of Chicago Survey Lab; Charlotte C Lawson, University of Pennsylvania; Brendan Saloner, University of Pennsylvania; Daniel Polsky, University of Pennsylvania

Presenter: Karin Rhodes, M.D., M.S., Director, Emergency Care Policy Research, University of Pennsylvania, School of Medicine, kvr@sp2.upenn.edu

Research Objective: The goals of this study are to provide valid estimates of baseline primary care capacity and to assess variation in access for both urgent and routine appointments by insurance status, prior to the implementation of the major coverage provisions of the Affordable Care Act (ACA). We estimate how the proportion of physician offices accepting new patients and average wait times for appointments vary across 10 states (AR, GA, IA, IL, MA, MT, NJ, OR, PA, and TX) for non-elderly adults, overall and by insurance status. The states have been selected to be diverse in terms of their region, size, population density, primary care provider workforce, reliance on Medicaid Managed Care, generosity of Medicaid payment rates, and projected increase in coverage under the ACA.

Study Design: This study uses a simulated patient methodology to measure the extent to which trained field staff, using piloted scripts and posing as patients, are able to schedule actual appointments with a primary care provider for either a routine or an urgent health care concern
– a new diagnosis of hypertension. Callers with each condition were assigned to either Medicaid, commercial, or no insurance coverage. Each caller stated a specific insurance plan that data suggested the provider accepted. All appointments were cancelled at the end of the call.

**Population Studied:** We selected a stratified random sample of practices at the county level to produce representative samples in each state. Each practice (the unit of analysis), defined as a unique primary care site address and phone number, was identified from a comprehensive list of primary care providers and confirmed through a ‘call through’ of the entire sample.

**Principal Findings:** The screening calls revealed a total of 9,799 eligible primary care practices in the 10 study states. The simulated patient calls are currently underway with completion anticipated in late February/early March. Initial results will be available at the June AcademyHealth meeting. To-date, 6,460 cases have been completed. Of these, 53 percent resulted in an appointment being granted, 27 percent resulted in a straightforward “no”; 14 percent resulted in a hypothetical or vague appointment, likely available when they provide their insurance number. In 5 percent, appointment availability could not be ascertained due to appointment system barriers; 1 percent were walk-in clinics only.

**Conclusions:** The study will provide important new information on variation in access to primary care by insurance status for both urgent and routine appointments. Results can be used to monitor access to primary care over time and identify how primary care access varies, within a given insurance status and state.

**Implications for Policy, Delivery, or Practice:** There is a limited window to establish a clear baseline measure of current primary care capacity within each insurance condition prior to the large increase in enrollment expected to begin in 2014. If this is not well documented, it will be very difficult to assess how the ACA has affected primary care access. Results from simulated patient methodology serve to assess the validity of other measures of access, such as traditional provider and patient surveys.

**How Does Primary Care Access Promote Utilization of Preventive Health Care? Evidence from an Experimental Audit Study**

Brendan Saloner, University of Pennsylvania; Karin Rhodes, University of Pennsylvania; Jenny Kenney, Urban Institute; Daniel Polsky, University of Pennsylvania

**Presenter:** Brendan Saloner, Ph.D., RWJ Health And Society Scholar, Health Policy, University of Pennsylvania, bsaloner@gmail.com

**Research Objective:** Primary care is the principal setting in which adults receive routine preventive care such as influenza vaccinations and pap smears. Several studies have identified limited availability of primary care providers as a substantial barrier to receiving preventive care. It is difficult, however, to measure whether barriers to primary care primarily stem from limited supply of providers, versus patient-level factors, such as insurance coverage or preferences for care. Our objective is to measure how much availability of primary care appointments explains variation in utilization of preventative health care by using novel measures from an experimental audit study.

**Study Design:** The audit study provides comparable data on availability of primary care on the eve of health reform in 10 politically and geographically diverse states. Field staff are calling at least 1,000 adult primary care providers in each of 10 states posing as prospective patients. The calls follow a standardized script, except that the reason for the visit and the patient’s insurance status (Medicaid, private, uninsured) are experimentally manipulated. Using the audit study data, we will calculate a county-averaged probability of receiving a visit for different insurance groups, and an average wait time for a visit. County-level measures will be linked to individual-level data from the Behavioral Risk Factor Surveillance System (BRFSS). BRFSS collects data on physical exams, pap smears, prostate exams, and influenza vaccinations. BRFSS releases county identifiers for the most populous counties in the United States. For our 10 states, BRFSS identifies 69 counties covering 50,506 non-elderly adults.

We will estimate the probability that an individual utilizes preventive care based on the average availability of primary care appointments in the individual’s county. Our primary regression
specification will include individual-level demographic and health status covariates. These models will be estimated for the full sample, and for subgroups of interest (sex, race, insurance status). We will also assess whether the relationship between appointment availability and primary care utilization is mediated by county-level variables, such as poverty and uninsured rates.

**Population Studied:** Non-elderly adults (age 18 to 65) residing in 69 populous counties in 10 states.

**Principal Findings:** Data collection for the audit study will be completed in March 2013. These measures will be linked to the BRFSS and preliminary results will be available at the June AcademyHealth meeting. Analysis of the BRFSS reveals substantial variation across counties in our sample in use of preventative health care. For example, the median past-year checkup rate was 71.9 percent, but the range was 48.9 to 85.3 percent. Other measures such as influenza vaccinations and pap tests also exhibited substantial ranges. Rates of screening for all measures was lower for low-income, uninsured, and minority populations.

**Conclusions:** Our study will systematically characterize the relationship between availability of primary care appointments and preventive care at a county level, and highlight particular populations that may be affected by limited provider availability.

**Implications for Policy, Delivery, or Practice:** Findings will help state and local policymakers determine how to strategically invest in expanding provider workforce as they prepare to simultaneously expand health insurance coverage under the Affordable Care Act.

**Implication of Immigration Reforms for Children’s Health Insurance Coverage**

Eric Seiber, Ohio State University; Paula Song, Ohio State University; Kelly Balistreri, Bowling Green State University; Karoline Mortensen, University of Maryland

**Presenter:** Eric Seiber, Ph.D., Assistant Professor, Health Services Management and Policy, Ohio State University, seiber.7@osu.edu

**Research Objective:** U.S. health policy greatly favors health insurance coverage for children, although significant gaps in coverage exist among children in immigrant families. Although the ACA expands health insurance coverage for both adults and children, it fails to address insurance coverage for immigrants. Adding to the complexity of immigrant health policy is the mixed composition of immigrant families, where children often have U.S. citizenship while their parents do not. This paper examines the role of immigration in coverage gaps for children.

Specifically, this paper (1) identifies the share of uninsured children living in immigrant families, (2) demonstrates the role of the child’s citizenship in obtaining coverage, and (3) uses decomposition techniques to identify an upper bound reduction in the child uninsured rate if these children gain citizenship through legislative action.

**Study Design:** This study uses the 2008-2011 American Community Surveys to estimate probit models of insurance status. Since US Census data does not collect information on immigration status (i.e., legal residency), a Fairlie decomposition reveals the potential reduction in the uninsured rate for children from extending citizenship to undocumented children.

**Population Studied:** The American Community Survey’s representative sample of all children under age 18 includes 2.5 million children from 2008-2011, including over 600,000 children with immigrant parents.

**Principal Findings:** Having an immigrant parent is a defining characteristic of uninsured children. While children in immigrant families are only 24.1% of all children in the United States, they comprise almost half (42%) of all uninsured children in the US. These children live in immigrant families and have at least one immigrant parent, but 69% of those uninsured immigrant children already hold US citizenship. The decomposition analysis demonstrates that citizenship of the parent explains the largest difference in the uninsured rate for these children.

**Conclusions:** Children with immigrant parents are almost half of all uninsured children in the United States. The high percentage of uninsured children in immigrant families is not due to the child’s immigration status since 2/3 are already US citizens. If immigrant children gain citizenship, most of these children will remain uninsured unless the immigration status of their parents also changes.

**Implications for Policy, Delivery, or Practice:** While a child’s immigration status determines their eligibility for Medicaid and other public benefits, parents must be willing to enroll the child. This paper shows that immigration
reforms that only extend citizenship to children will have little spillover benefits in reducing the number of uninsured children in the United States. Children in immigrant families will remain disproportionately uninsured if immigration reform does not extend to their adult parents.

**Emergency Department Utilization and the Uninsured: Does Length of Coverage Gap Matter?**

Dan Shane, University of Iowa

**Presenter:** Dan Shane, Ph.D., M.A., Assistant Professor, Health Management and Policy, University of Iowa, dan-shane@uiowa.edu

**Research Objective:** In this paper, we tie together two important issues related to ACA health insurance reforms: coverage dynamics and emergency department utilization. We take aim at a group of people often overlooked in analyses of the uninsured and studies examining the impact of health insurance coverage on emergency department utilization: the temporarily uninsured. Can we expect significant changes in emergency department utilization for people gaining full insurance coverage after suffering a temporary gap in coverage? How do these changes compare to the long-term uninsured gaining full coverage?

**Study Design:** We evaluate the demographic and socioeconomic makeup of the temporarily uninsured and assess whether they can be meaningfully referred to as frictionally uninsured. Frictionally uninsured refers to the status of individuals that are temporarily without insurance coverage due to a job transition. In that context, we seek to understand whether overall macroeconomic trends impact this group differently than individuals continuously without coverage. Using MEPS data we further address the idiosyncrasies of this group as they relate to emergency department usage. By incorporating a treatment-effects specification that controls for self-selection into health insurance we pinpoint how partial coverage gaps impact emergency department utilization, both emergency and non-emergency visits.

**Population Studied:** Nationally representative population of 18-64 year-olds divided into three groups: insured, temporary coverage gap, continuously uninsured.

**Principal Findings:** Our findings suggest that virtually all the meaningful decreases in emergency department utilization that occur due to expanding health insurance accrue from fewer visits by people that suffered only temporary gaps in coverage. We further find that temporary lack of coverage leads to significantly more ED visits tagged as non-urgent.

**Conclusions:** Temporary gaps in insurance coverage appear to result in significantly more trips to the emergency department and often for non-urgent reasons. Our results suggest that meaningful reductions in ED usage from expanding insurance will largely come from eliminating temporary gaps in coverage rather than from expanding coverage to the long-term uninsured.

**Implications for Policy, Delivery, or Practice:** We explore the mechanisms for the aforementioned utilization patterns and discuss the policy implications for these important findings. Outreach to groups experiencing job transitions to prevent gaps in insurance coverage may be critical to reducing reliance on emergency departments, particularly for non-urgent uses.

**A New Data Source for Health Services Research: Evaluating the Gallup-Healthways Well-Being Index**

Laura Skopec, US Department of Health and Human Services; Thomas Musco, Office of the Assistant Secretary for Planning and Evaluation, US Department of Health and Human Services; Benjamin D. Sommers, Harvard School of Public Health

**Presenter:** Laura Skopec, M.P.P., Program Analyst, Office of the Assistant Secretary for Planning and Evaluation, US Department of Health and Human Services, lauraskopec@yahoo.com

**Research Objective:** This analysis describes the Gallup-Healthways Well-Being Index (WBI), a daily national phone survey of adults focused on health and wellness. Our objective was to compare Gallup’s health-related estimates to other established national surveys and identify potential areas where the WBI might be particularly useful for policy research.

**Study Design:** We compared several years of Gallup survey data for adults ages 18 and over to established national surveys in several
domains. The surveys used for comparison were the Current Population Survey (CPS), the American Community Survey (ACS), the Medical Expenditure Panel Survey (MEPS), the National Health Interview Survey (NHIS), and the Behavioral Risk Factor Surveillance System (BRFSS). We compared demographic characteristics of Gallup’s sample to those in the CPS, ACS, and NHIS; health insurance information by type of coverage, year, and state to the CPS, ACS, and NHIS; measures of access to care to the NHIS, MEPS, and BRFSS; and health status measures to the CPS, NHIS, and MEPS. For insurance coverage rates by state and over time, we used Pearson correlation coefficients to describe the relationship between Gallup estimates and other datasets. All analyses accounted for each survey’s design and were weighted to produce nationally-representative estimates.

Population Studied: Nationally-representative samples from 6 different surveys, containing all adults ages 18 and over, for the years 2008-2012.

Principal Findings: Gallup’s post-weighted sample is similar in age, race/ethnicity, and education to the CPS, ACS, and NHIS. Income is more frequently not reported in Gallup data than in the CPS, ACS, and NHIS, which use imputation for missing values. Gallup’s survey produces similar national, state, and time-trend estimates on overall rates of insurance coverage as other surveys, with correlation coefficients between Gallup estimates and other surveys ranging from 0.70 to 0.87 for annual uninsured rates, and 0.89 to 0.95 for state-level estimates. Gallup differs in its coverage question (allowing only one type of insurance per person), and produces much lower rates of Medicare and Medicaid coverage than other surveys. Access to care, self-reported prevalence of several chronic diseases, and overall health status estimates were similar in Gallup and other surveys.

Conclusions: The Gallup WBI is a potentially valuable complement to existing data sources for health services research. Gallup WBI measures numerous outcomes related to health policy and has the advantages of allowing for national and state-specific estimates with a rapid turnaround time (less than a week from survey administration to data availability). For population demographics, overall rates of insurance coverage, access to care, and health status, Gallup data are reasonably similar to other well-established national surveys.

Estimates of type of insurance are less comparable, particularly for public coverage.

Implications for Policy, Delivery, or Practice:
The Gallup WBI could serve as an effective data source for tracking population changes in coverage over time and within states, before data from the other national surveys are released. The WBI could be particularly useful as an early indicator of the effectiveness of major coverage expansions such as those planned for 2014 under the Affordable Care Act.

Commercial Health Insurance Markets: Concentration, Cost Trends and Policy Implications

Kristof Stremikis, The Commonwealth Fund; Cathy Schoen, The Commonwealth Fund; David Radley, The Commonwealth Fund; Jacob Lippa, The Commonwealth Fund

Presenter: Kristof Stremikis, Senior Researcher, The Commonwealth Fund, ks@cwf.org

Research Objective: To update previous analysis of health insurance enrollment in the United States and determine the level of concentration in national, state, and local health insurance markets. Additionally, uncover recent trends in the financial performance of the five major for-profit carriers and review related research on the impact of enrollment concentration on profit and market dynamics.

Study Design: Calculation of insurer market share is based on Health Leaders Interstudy data of commercial health insurance enrollment in HMO and PPO markets in 2011. Insurance firm financial data is derived from publicly reported tax filings.

Population Studied: Commercially insured (employer-sponsored and individual) adults with HMO and PPO coverage throughout the United States. Financial data are from the five largest commercial health insurers in the country—UnitedHealth Group, WellPoint, Aetna, CIGNA, and Humana.

Principal Findings: Analysis of health insurance enrollment in 2011 shows that the majority of U.S. health insurance markets are highly concentrated, with the three largest carriers comprising 70 percent or more of commercial enrollment in nearly 30 states and a single dominant insurer enrolling more than 50 percent of commercially insured lives in eight

Has the 'Massachusetts Experiment' Worked for the Working Poor?
Liane Tinsley, New England Research Institutes; Susan Hall, New England Research Institutes; John McKinlay, New England Research Institutes

Presenter: Liane Tinsley, M.P.H., Associate Research Scientist, Department of Epidemiology, New England Research Institutes; ltinsley@neriscience.com

Research Objective: To examine whether the 2007 implementation of a health insurance mandate, with available subsidized health insurance, resulted in increased coverage levels and increased health care access among persons defined as 'working poor' (WP) in Boston, Massachusetts. Data for an epidemiologic cohort study were collected before (2002-2006) and after the mandate (2007-2010), creating the conditions for a natural experiment.

Study Design: The Boston Area Community Health (BACH) Survey is a prospective study conducted in a representative sample of 4,144 Boston, MA residents aged 30-79 at baseline (T1, 2002-2005); follow-up data were collected during 2006-2010 (T2). The latter period was further stratified as pre- and during-mandate (July 1, 2006 - December 31, 2008) and post-mandate (January 1, 2009 - October 7, 2010). Information on household income, health insurance coverage, and health care provider (HCP) visits was obtained using in-person interviews. To avoid confounding by new eligibility for Medicare, persons aged >65 at T2 were excluded, as were those no longer residing in MA (resulting N=3,052: 996 black participants; 1,087 Hispanic; 969 white). WP were defined as those 'currently working for pay' with a household income <200% of the federal poverty threshold; non-working poor (NWP) as those reporting any work status other than "working for pay" with a household income <200% of the federal poverty threshold; and not poor (NP) as those reporting a total annual household income >=200% of the US federal poverty threshold.

Population Studied: A community-based sample of men and women living in Boston and participating in the T1 and T2 surveys.

Principal Findings: At T1 and T2, 18.5% and 17.7% of participants, respectively, met the definition of WP. At T1, 26.5% of WP reported no health insurance, compared to 15.7% of NWP and 8.4% of NP. The proportion of WP reporting no insurance was greatly reduced at T2, especially among those whose interviews were conducted post-mandate. Among WP interviewed pre- and during-mandate, 15.5% reported no health insurance compared to 10.0% interviewed post-mandate; corresponding proportions among NWP were 4.4% and 5.0%, and 9.0% and 0.9% among NP. HCP visits among all three groups improved following reform implementation, but gaps in health care access between WP and others were not entirely ameliorated.

states. At the local level, three dominant plans control more than 70 percent of the market in more than three-fourths of the nation's 366 metropolitan statistical areas. Meanwhile, the health insurance industry as a whole continues to enjoy strong financial performance, despite continual increases in underlying medical costs and declining enrollment in employer-sponsored coverage products.

Conclusions: Oligopoly is the norm rather than the exception in health insurance markets at both the state and local level. Coincident to the trend toward consolidation, the health insurance industry as a whole has enjoyed a sustained period of strong financial performance despite continual increases in underlying medical costs and declining enrollment in employer-sponsored coverage products throughout the past decade.

Implications for Policy, Delivery, or Practice: Excessive market concentration is typically harmful when viewed through the lens of consumer welfare, and may auger for public regulation in some circumstances. However, the consolidation of purchasing power among dominant payers could also be used to effectively offset bargaining power among concentrated hospitals and physician groups, leading to lower reimbursement rates and increased pressure to slow the overall rate of medical cost growth. Related research and several recent private sector initiatives provide some evidence to this effect, and demonstrate that powerful carriers can constructively utilize their market position to deploy innovative payment arrangements in support of high-value health care. Specific insurance market reforms contained within Affordable Care Act provide the opportunity to magnify these initiatives and leverage existing dynamics to better serve the public interest.
Conclusions: Comparing T1 and the post-mandate period, the implementation of a subsidized health insurance program and a health insurance mandate was associated with substantial gains in health insurance coverage and a reduction by more than half in the proportion of WP who were uninsured. Health care utilization also appeared to increase among all three groups. Despite these gains, the WP in our study were more likely to remain uninsured post-mandate (10.0% WP vs. 5.0% NWP vs. 0.9% NP), suggesting that its reach was not universal. Strengths of our study include race/ethnic and socioeconomic diversity and the ability to stratify follow-up into pre-/during-implementation vs. post-implementation periods, which helps rule out the potential influence of secular trends that may have been operating independently of the policy change.

Implications for Policy, Delivery, or Practice: Our study suggests that both the WP and others in MA benefitted from the implementation of state health care reform.

Implementation Findings of the Children’s Health Insurance Program Outreach and Enrollment Grant Program among American Indian and Alaskan Native Organizations

Nathan West, RTI International; Kathleen Farrell, RTI International; Melissa Farrell, RTI International; Rebecca Perry, RTI International

Presenter: Nathan West, M.P.A., Research Health Analyst, Department of Health Economics Research, RTI International, nathanwest@rti.org

Research Objective: Evaluate the CHIP Outreach and Enrollment Grant program as implemented by American Indian/Alaskan Native (AI/AN) grantee organizations. Determine effective strategies to enroll and retain eligible AI/AN children, identify major challenges and how to address them, and identify key lessons learned that can be used to inform other initiatives.

Study Design: Reviewed grant applications and quarterly and annual reports on grant activities and outcomes. Collected additional information from grantees through telephone interviews and e-mail communications. Synthesized information from reports and interviews into standardized annual report summaries. Study results cover two years of a three-year grant period.

Population Studied: 41 AI/AN grantees, which include health programs operated by tribes/tribal organizations, Indian Health Services (IHS) providers, and urban Indian organizations.

Principal Findings: Strategies employed fell into three broad categories: 1) application assistance, 2) outreach, and 3) partnerships with other organizations. More than half of the grantees implemented strategies in all three categories. Many grantees were able to use the IHS Resource and Patient Management System (RPMS) to generate client lists, which they used as a starting point to identify uninsured children and offer application assistance. Other grantees obtained lists from state agencies or other tribal needs-based programs. Grantees provided application assistance in easily accessible venues, including schools, residential group homes, and health care centers within their geographic area. Twelve new application sites were established and 30 new outreach workers were hired by grantees using grant funds during Year One. Primary outreach strategies included disseminating information (e.g. brochures, letters) about CHIP/Medicaid at community events such as tribal-sponsored pow-wows and health fairs, and through social workers in other needs-based programs. Nearly all grantees mailed letters, notices and applications to families with uninsured children or enrolled children who were approaching their renewal dates. Grantees often partnered with other needs-based programs within their tribes to identify eligible children, but some also formed nontribal partnerships with community organizations and health care providers that provide services to the target population. The most significant challenge faced by nearly all grantees is counting the belief among AI/AN families that their children do not need CHIP/Medicaid because they receive health care through IHS providers, or that enrolling in CHIP/Medicaid will result in a loss of other tribal-based benefits. In addition, AI/AN families are reluctant to disclose personal information that they consider private or embarrassing. Finally, geographic barriers are significant among many AI/AN families since most tribal members live in remote areas that are rural or frontier, requiring long travel distances to seek medical care and other basic services.

Conclusions: Tribal organizations are in a unique position to provide outreach and enrollment assistance to AI/AN families because they have credibility with the target population.
Implications for Policy, Delivery, or Practice:
Recent U.S. Census data show that 23 percent of AI/AN children are uninsured. The findings provide policymakers, state officials, and other stakeholders with important insights into effective approaches for reaching AI/AN children, an important subgroup that CMS and states should continue to focus on as the ACA is implemented.

State-Level Immigration Laws and Immigrants’ Access to Health Care: Implications for National Reform
Kari White, University of Alabama at Birmingham; Valerie A. Yeager, Tulane University; Nir Menachemi, University of Alabama at Birmingham; Isabel C. Scarinci, University of Alabama at Birmingham

Research Objective: In the absence of national immigration reform, state legislatures have increasingly proposed measures to address local immigration issues. In 2011, Alabama became one of five states to pass omnibus legislation requiring verification of lawful US residence for individuals seeking public benefits, such as health care, from state and local agencies. There has been little systematic study of the impact these state-level initiatives have had on access to health care. We assess how Alabama’s law, HB56, has affected Latino immigrants’ use of health services across several dimensions of access to care.

Study Design: Between May and July 2012, we conducted in-depth interviews with Latina immigrant women, recruited through snowball sampling. We used theoretical sampling to capture experiences across subgroups whose characteristics were most likely to influence access: women with a current or recent pregnancy (since prenatal care is exempt from HB56’s documentation requirements) and children’s country of birth. We analyzed interview transcripts by coding emerging themes in women’s responses about getting health care since HB56 was passed and categorizing themes according to five dimensions of access: availability, accessibility, affordability, accommodation, and acceptability. We then compared themes across subgroups based on women’s pregnancy status and their children’s country of birth.

Population Studied: Thirty Latina immigrants between 19 and 49 years of age with children less than 18 years old; resided in Jefferson County, Alabama; and were living in Alabama when HB56 was passed. Our subgroups included 15 women with US-born children, 15 with at least one foreign-born child, 20 non-pregnant women and 10 pregnant/postpartum women.

Principal Findings: The most common way that HB56 impacted access was by affecting the availability of health services. Women frequently stated they were afraid that local clinics and hospitals would no longer see them or their children if they presented for care, leading some to rely on home remedies or over-the-counter medications instead of seeking care in the formal health sector. Additionally, there were several cases in which women and children were eligible but denied services because administrative staff seemed unaware of exemptions under the law. Many women reported being worried about being able to afford health care because they are now forced to seek services in the private sector where costs are substantially higher, and have experienced financial insecurity following the law. Women’s perceptions of local clinics’ abilities to meet their needs were also affected due to perceived discriminatory treatment by clinic staff and fears that they would be reported to authorities for seeking services. Accessibility to care due to fears of driving without documentation of lawful US residency was not a common barrier to use of health services, but remained a concern for women who continued to make medical visits. Overall, non-pregnant women and those with foreign-born children more frequently experienced barriers preventing them from obtaining care.

Conclusions: Alabama’s immigration law has adversely affected Latino immigrants’ use of health services by impacting several dimensions of access, which may increase health disparities.

Implications for Policy, Delivery, or Practice: HB56 and similar laws may have unintended consequences for public health if immigrants are prevented from accessing preventive and primary care.

Trust Me, I’m Medicaid: Physician Uptake of New Medicaid Patients in the Face of Varying Fees
Adam Wilk, University of Michigan School of Public Health; Jodyn Platt, University of Michigan School of Public Health

Presenter: Adam Wilk, A.B., PhD Student, Health Management and Policy, University of Michigan School of Public Health, awilk@umich.edu

Research Objective: Increasingly primary care providers (PCPs) indicate they will not accept new Medicaid patients. Yet, largely due to the Affordable Care Act (ACA), there may be as many as 21 million new Medicaid enrollees by 2022. To help incentivize PCPs to meet the growing demand, the ACA increases Medicaid fees for primary care services to 100% of Medicare fees during 2013 and 2014, after which federal subsidies go away. We explore whether PCPs refrain from accepting new Medicaid patients because fees are insufficient or because of waning trust in Medicaid to maintain or increase fees moving forward. We develop a dynamic Markov model of PCP decisions to accept new Medicaid patients and examine the importance of trust between PCPs and Medicaid in these decisions. Interaction effects provide additional insights into how physicians may respond to varying fees, suggesting new strategies Medicaid agencies may undertake to more effectively engage physicians.

Study Design: Using an interdisciplinary framework, we parameterize six dimensions of trust relevant to the PCP-Medicaid relationship: Medicaid’s reputation, commitment to an ongoing relationship, moral imperative to act on behalf of Medicaid beneficiaries rather than in self-interest, the PCP’s past experience with Medicaid, Medicaid’s demonstrated reliability, and contextual factors. We use flexibly-specified linear and non-linear panel data models to investigate how these parameters affect the probability that a PCP accepts new Medicaid patients. Interactions between trust parameters and a proxy variable for Medicaid fee generosity help predict how trust affects physician responses to elevated or reduced fees.

Principal Findings: We observe that multiple dimensions of trust – Medicaid’s reputation and PCPs prior experience, in particular – have modest, positive, and significant effects on PCP choices to accept new Medicaid patients. Moreover, our analysis of interaction effects reveals that the state’s commitment to the Medicaid program, among other dimensions, may substitute for higher fees in motivating PCPs to accept new Medicaid patients. Controlling for dimensions of trust and other factors, the effects of Medicaid fee generosity on the PCP’s propensity to accept new Medicaid patients are distinguishable from zero in only half of the evaluated specifications.

Conclusions: PCPs’ trust of their state Medicaid agencies is likely to affect their willingness to accept new Medicaid patients both when fees are relatively high, as they will be during 2013 and 2014, and after they (potentially) decline in 2015. For many PCPs, the level of trust in Medicaid may be more important than Medicaid fee generosity when deciding to accept Medicaid patients.

Implications for Policy, Delivery, or Practice: Medicaid should seek to instill greater trust among PCPs (e.g., through transparency, follow-through on commitments, and policy consistency) to encourage them to accept new Medicaid patients during the coming years.

Charges and Expenditures from Ambulatory Care Sensitive Emergency Room and Inpatient Visits Predicted by Past Year Unmet Healthcare Need among Children in the United States
Lauren Wisk, University of Wisconsin Madison

Presenter: Lauren Wisk, B.S., Doctoral Candidate, Department of Population Health Sciences, University of Wisconsin Madison, wisk@wisc.edu

Research Objective: We sought to determine if unmet healthcare need was associated with
ambulatory care sensitive (ACS) emergency room and inpatient charges and expenditures among children in the US, using a nationally representative, population-based sample. **Study Design:** We examined data on 22,581 children from the 2002-2007 Medical Expenditure Panel Survey. Unmet need was defined as delayed or forgone healthcare during the first survey year. Charges, expenditures and out-of-pocket (OOP) costs associated with ACS utilization were evaluated during the second survey year. Expenditures for non-ACS utilization during the second year were also evaluated as a comparison. Multivariable two-part models were used to determine if children who experienced past year unmet healthcare need had higher ACS expenditures in the following year, adjusting for relevant covariates (including: child age, gender, race/ethnicity, health insurance, activity limitation status, usual source of care, parental education, family composition, family income, US region of residence, urbanicity, and time). **Population Studied:** US children aged 0 to 17 years. **Principal Findings:** 4.77% of children with unmet need experienced any costs associated with ACS visits, compared to 3.02% for those without unmet need (p<0.01); while 11.57% of children with unmet need experienced any costs associated with non-ACS visits, compared to 12.23% for those without unmet need (p=0.03). Multivariable analyses revealed that children with unmet need were 1.69 times more likely to have any ACS charges than children without unmet need (95% CI: 1.15-2.49), but there were no significant difference in the odds of experiencing any non-ACS charges for children with and without unmet need (OR 1.19, 95% CI: 0.97-1.45). Non-ACS expenditures and OOP costs were not significantly different for those children with and without unmet need. Children with unmet need were more like to have any ACS expenditures than children without unmet need; while among those with any ACS costs, children with unmet need had significantly lower charges and expenditures but significantly higher OOP costs. **Conclusions:** As unmet need was associated with increased ACS costs but not non-ACS costs, it is less likely that the difference in ACS costs were driven by a general preference to receive care in a hospital. Instead, families may be substituting prior delayed or forgone ambulatory care with emergency room and inpatient care. Charges and expenditures for children with unmet need and any ACS costs may be lower because their conditions are less severe, while co-occurring OOP costs may be higher due to less generous insurance coverage. Ironically, families may be seeking care in the ER instead of a clinic because of their less generous insurance coverage. Alternatively, charges and expenditures may be lower because families are refusing expensive services because the associated OOP costs are too great, possibly also due to less generous insurance coverage. **Implications for Policy, Delivery, or Practice:** Regardless of the mechanism, children with unmet need and high ACS costs reflect families with clear barriers to accessing appropriate preventive care. Ensuring that families understand their insurance benefits may help to ensure appropriate utilization while simultaneous decreasing their OOP costs. Both insurers and providers can play a role in ensuring appropriate utilization by preventing unmet need. **Funding Source(s):** Other, RWJF Dissertation Grant **Poster Session and Number:** C, #1059 **Medicaid and CHIP Retention among Children in Nine States** Angie Wong, Stony Brook University and Stony Brook Long Island Children's Hospital; Susmita Pati, Stony Brook University and Stony Brook Long Island Children's Hospital; Ashley Zeigler, The Children's Hospital of Philadelphia; Rose E. Calixte, Stony Brook University and Stony Brook Long Island Children's Hospital; Justin Ludwig, The Children's Hospital of Philadelphia; A. Russell Localio, The University of Pennsylvania Perelman School of Medicine; Jeanhee H. Moon, The Children's Hospital of Philadelphia; Jeffrey H. Silber, The Children's Hospital of Philadelphia **Presenter:** Angie Wong, MHS, Research Coordinator, Pediatrics, Stony Brook University and Stony Brook Long Island Children's Hospital, angie.wong@stonybrookmedicine.edu **Research Objective:** Despite federal mandates, states control many aspects of public health insurance program implementation that may result in differences in public insurance retention rates between states. Understanding differences between metrics used to assess public insurance retention rates is a critical first step for policy decision-makers.
Study Design: Three metrics were used to measure public insurance retention: (1) Duration metric – a prospective metric that quantifies the number of newly enrolled children continuously enrolled in public insurance coverage after initial enrollment during a pre-specified observation period; (2) Newborn duration metric – a similar measure to Duration but focusing only on newly enrolled newborns; (3) Coverage metric – a prospective metric that quantifies the ratio of time an individual is enrolled over an 18 month interval.

Population Studied: Data from the 2006-2008 Medicaid Analytic Extract were used to examine these three metrics in nine selected states: Illinois, Louisiana, Montana, New Hampshire, New York, North Carolina, Ohio, Oregon, and Utah.

Principal Findings: Public insurance retention rates vary greatly among states and with using different metrics. For the duration metric, the retention rate ranges from 26.3 percent of children continuously enrolled for 18 months in Utah to 71.2 percent in Illinois. The retention rates for the newborn 18-month duration metric are slightly higher, ranging from 29.0 percent in Utah to 81.8 percent in Illinois. In contrast, using the duration metric, a child is covered by insurance 54.4 percent of an 18 month period in Utah to 80.1 percent of an 18 month period in Illinois.

Conclusions: Variation in public insurance retention rates between states and with using different metrics raises concerns about existing practices to support continuous public health insurance for eligible children.

Implications for Policy, Delivery, or Practice: As healthcare reform unfolds, multi-pronged and multi-level strategies to retain eligible children merit serious consideration.

Association of Ambulatory Care Sensitive Conditions with Public Insurance Coverage
Angie Wong, Stony Brook University and Stony Brook Long Island Children's Hospital; Susmita Pati, Stony Brook University and Stony Brook Long Island Children's Hospital; Ashley Zeigler, The Children's Hospital of Philadelphia; Rose E. Calixte, Stony Brook University and Stony Brook Long Island Children's Hospital; Justin Ludwig, The Children's Hospital of Philadelphia; A. Russell Localio, The University of Pennsylvania Perelman School of Medicine; Jeanhee H. Moon, The Children's Hospital of Philadelphia; Jeffrey H. Silber, The Children's Hospital of Philadelphia

Presenter: Angie Wong, MHS, Research Coordinator, Pediatrics, Stony Brook University and Stony Brook Long Island Children's Hospital, angie.wong@stonybrookmedicine.edu

Research Objective: Though conventional wisdom holds that stable continuous insurance coverage is associated with increased preventive care and, in turn, decreased likelihood of hospitalization, limited literature has quantified the relationship between public insurance retention and pediatric hospitalizations for ambulatory care-sensitive conditions (ACSCs). This study aims to determine the association between public insurance retention and hospitalizations for ACSCs for children.

Study Design: The average insurance retention in a given child's county of residence was calculated using two different insurance metrics: 1) Duration: percentage of newly enrolled children continuously enrolled for 18 months after initial enrollment; 2) Coverage: the ratio of time a child is enrolled over an 18 month interval. Multivariable regression models including gender, age, race/ethnicity, presence of chronic conditions, and geography were created to determine the association of insurance retention with a child's odds of ACSC hospitalization.

Population Studied: The 2006-2008 Medicaid Analytic Extract data from nine states were used: Illinois, Louisiana, Montana, New Hampshire, New York, North Carolina, Ohio, Oregon, and Utah.

Principal Findings: ACSC hospitalization rates ranged from 0.29 percent in Oregon to 2.41 percent in Illinois using the duration metric and 0.22 percent in Oregon to 1.39 percent in Illinois using the coverage metric. In general, both Coverage and Duration insurance retention measures showed a significant association with ACSC hospitalizations, but in the direction of increased insurance retention leading to increased likelihood of hospitalization. The fully adjusted models demonstrated that a 10 percent increase in the average county-level coverage at 18 months was significantly associated with an increase in a child's odds of an ACSC hospitalization in 7 of 9 states (Illinois 15 percent, Louisiana 32 percent, Montana 89 percent, New Hampshire 45 percent, New York 32 percent, Oregon 36 percent, Utah 68 percent).
percent) as well as the average county-level duration of enrollment in 6 of 9 states (Illinois 12 percent, Louisiana 58 percent, Montana 5 percent, New York 16 percent, Ohio 9 percent, Oregon 44 percent).

**Conclusions:** Contrary to expectations, greater insurance retention is associated with higher likelihood of hospitalization for ACSCs.

**Implications for Policy, Delivery, or Practice:**

Children in this study sample were selected based on Medicaid eligibility files and have a higher ACSC rate than the national average, thus other unmeasured characteristics may be confounding the result. Further study will be required to confirm the results.

**Disparities in Continuity of Public Health Insurance Coverage among Vulnerable Children**

Angie Wong, Stony Brook University and Stony Brook Long Island Children's Hospital; Susmita Pati, Stony Brook University and Stony Brook Long Island Children's Hospital; Ashley Zeigler, The Children's Hospital of Philadelphia; Rose E. Calixte, Stony Brook University and Stony Brook Long Island Children's Hospital; Justin Ludwig, The Children's Hospital of Philadelphia; A. Russell Localio, The University of Pennsylvania Perelman School of Medicine; Jeanhee H. Moon, The Children's Hospital of Philadelphia; Jeffrey H. Silber, The Children's Hospital of Philadelphia

**Research Objective:** Without stable insurance coverage, children -- especially those from vulnerable groups -- are more likely to experience delayed care, have unmet medical needs and do not have a usual source of care. This study aims to determine the disparities in public health insurance retention rates among children.

**Study Design:** The health insurance retention rates among the vulnerable groups of children were quantified using two different metrics: 1) Duration: percentage of newly enrolled children continuously enrolled for 6, 12, and 18 months after initial enrollment; 2) Coverage: the ratio of time a child is enrolled over an 18 month interval. Multivariable logistic regression models were used to further determine differences in public health insurance retention rates between vulnerable groups of children.

**Population Studied:** Using 2006-2008 Medicaid Analytic Extract data from nine selected states, insurance retention was compared for two vulnerable groups: racial/ethnic minorities and children with special health care needs (CSHCN). Race/ethnicity was classified based on Office of Management and Budget guidelines. CSHCN were identified using a list of pediatric chronic conditions compiled based on published peer-reviewed literature.

**Principal Findings:** Compared to non-Hispanic white children, non-Hispanic black children in most states were most likely to retain coverage at 18 months. Using the duration metric, retention rates for 18 months among non-Hispanic white children ranged from 26.6 - 67.3 percent vs. 31.6 - 72.5 percent among non-Hispanic black children. Using the coverage metric, retention rates among non-Hispanic white children ranged from 53.9- 80.2 percent of the 18 month observation period, 60.7 - 83.2 percent among non-Hispanic black children, and 54.6- 81.9 percent among Hispanic children. In all states except Louisiana, CSHCN were more likely than their healthy peers to retain coverage at 6, 12, and 18 months. Duration at 6 months ranged from 81.8- 96.4 percent among CSHCN vs. 70.6- 95.4 percent among non-CSHCN. Duration at 12 months ranged from 60.9- 91.0 percent among CSHCN vs. 49.4- 82.8 percent among non-CSHCN. Duration at 18 months ranged from 36.1- 84.6 percent among CSHCN vs. 25.2- 66.1 percent among non-CSHCN. Using the coverage metric, CSHCN were insured 66.5- 88.9 percent of the 18 month observation period vs. 53.0- 80.8 percent among non-CSHCN. These disparities persisted in multivariate models including gender, age, race/ethnicity, presence of chronic conditions, and rural/urban residency.

**Conclusions:** Children from vulnerable populations are more likely to retain public health insurance coverage than their peers, but relatively low retention rates for vulnerable groups are cause for concern.

**Implications for Policy, Delivery, or Practice:** Strategies to increase public insurance coverage retention for vulnerable groups of children warrant attention.

State Mandated Insurance Benefits and Preventive Cancer Screenings
Wendy Xu, University of Minnesota; Bryan Dowd, University of Minnesota; Jean Abraham, University of Minnesota

Presenter: Wendy Xu, M.S., Ph.D candidate, Student, Health Policy and Management, University of Minnesota, wendyumn@gmail.com

Research Objective: This paper seeks to understand the association between state insurance mandates and utilization of several preventive cancer screenings, and the induced redistributive effects among consumers. The specific aims are: (1) to estimate the effect of state mandated benefits of preventive care on use of cancer screenings; (2) to estimate how non-price barriers relate to compliance with screenings; (3) to quantify the re-distributive effects of mandated coverage.

Study Design: Substantial variations with respect to the timing of state mandates that went into effect provided a natural experimental design for the study. A Difference-in-Difference model is paired with this design to estimate the change in utilization of preventive screenings because of state mandated benefits. The primary data comes from the 1997-2008 Medical Expenditure Panel Survey (MEPS). It is supplemented by the Area Resource Files (ARF) and the hand-collected state preventive mandates. The price of preventive cancer screenings paid by insurance plans is taken to be the national averaged insurer paid price listed on Healthcare Blue Book.com as the price of the interested services.

Population Studied: The analysis sample consists of privately insured adults with age and gender specific to the American Cancer Society (ACS) guidelines. The sample excludes people who are enrolled in Medicare or Medicaid any month during the survey year, as mandated benefits generally aim at private insurance. Those who reported a diagnosis of cervical, colon and prostate cancers are excluded from the respective sample.

Principal Findings: Overall, the findings suggest that mandated coverage does not increase consumption of preventive care either in aggregate or for different demographic subgroups. The findings are robust to a variety of sensitivity analyses. Some non-price social determinants are associated with large redistributive effects, including being an Asian, less educated, lack of English proficiency and lack of usual source of care, and living in isolated areas without adequate physician supply. It is shown that each individual who is eligible to use the service but have forgone it due to other barriers, potentially subsidize the users by $403.

Conclusions: While coverage mandates are ineffective in achieving increased cancer screening, mandates do result in income transfers from non-users to users of preventive care, and those transfers appear to be regressive – moving income from disadvantaged non-users to relatively well-off users.

Implications for Policy, Delivery, or Practice: This study reveals if mandatory coverage of preventive care is a wise use of limited resources that results in positive net benefits to consumers. Although reducing the out-of-pocket cost of preventive care has become a widely accepted public policy, state and federal governments should consider both the price effects and the distributional effects of mandate coverage with the essential health benefits of the reform. Mandated coverage has redistributive effects that may exacerbate the inequalities among individuals. Public policies that focus on the non-price factors affecting consumption of preventive care, such as increasing access to regular sources of care, education programs that target on people with poor health literacy, subsidies to language services for those difficult with English, and increasing physician availabilities in rural areas, might be both more efficient and more equitable, as well.

DISPARITIES AND HEALTH EQUITY

Health Disparities-Focused Health Services Research: Trends and Search Methodology
Philip Alberti, Association of American Medical Colleges; Nisha Shah, AcademyHealth; Beth Johnson, AcademyHealth; Erin Holve, AcademyHealth; Karey Sutton, Association of American Medical Colleges

Presenter: Philip Alberti, Senior Director, Health Equity Research And Policy, Association of American Medical Colleges, palberti@aamc.org

Research Objective: The federal government has made a clear commitment to reducing and eliminating health and healthcare inequities. However, there is no clear guidance for researchers on how to find relevant funded projects to identify current trends and gaps. This study aims to:
1. Define what disparities and equity research is with respect to Medical Subject Headings (MeSH) terms.
2. Analyze trends (2005-2011) in the funding, research focus (e.g. detect disparity, understand a disparity, or reduce/eliminate a disparity), population studied, health outcome investigated, and grantees institution of health disparities-focused HSR.
3. Develop search methods to validly ascertain the universe of funded, health-disparities focused HSR using the National Library of Medicine’s Health Services Research Projects in Progress (HSRProj) database.

Study Design: Based on an iteratively developed definition of ‘health disparities research’, queries were developed by delineating salient MeSH terms and keywords across relevant domains (e.g. “disparity”, “identity”, “methodology”, etc.), de-duplicating search results, and assessing the number of additional, unique records added by including additional terms.

Based on the results of this process, a query was developed that culled projects from the “disparity” and “identity” domains. This query was applied to the HSRProj database to identify the subset of health disparities-focused HSR projects newly funded between 2005 and 2011.

Principal Findings: Search methods for validly classifying HSR projects should be based on an a priori set of inclusion criteria derived from an explicit definition of the targeted research. Even with this grounding, though, we expect to discover that terms and keywords are not always consistently applied making conclusions difficult.

We hypothesize that despite the methodological challenges, there has been a consistent increase in the number of disparities-focused HSR projects between 2005 and 2011. Certain populations and health outcomes will be underrepresented in this research. Furthermore, the majority of projects still focus on documenting inequities or identifying their sources as opposed to developing and testing solutions.

Conclusions: As recent reports by the Centers for Disease Control (CDC 2011) and the Agency for Healthcare Research and Quality (AHRQ 2012) note, health and healthcare inequities exist across a wide array of outcomes and affect various population groups. Results of this current gap analysis will suggest specific areas and groups on which future health disparities HSR should focus.

Implications for Policy, Delivery, or Practice: The federal government, via both policy statements (e.g. Healthy People 2020) and funding mechanisms (e.g. NIH funded Health Disparities Centers of Excellence) has set the reduction and elimination of health and healthcare inequities as a major goal. The Affordable Care Act has furthered this work by setting demographic data collection standards, supporting community-based healthcare, and incorporating value-based healthcare metrics. Results of this research can guide federal and other funders so that resources are allocated to health outcomes and population groups currently underrepresented in disparities-focused HSR, as well as to projects that aim to build the evidence base for solutions to these gaps. Lessons learned from developing queries can also help refine NLM coding processes to more accurately tag research as health disparity-related research.

Funding Source(s): Other, This work is a joint effort between AcademyHealth and the American Association of Medical Colleges (AAMC). The analysis was provided under the auspices of the HSRProj program, funded by the National Library of Medicine, National Institutes of Health, Depa

Is Patient English Language Proficiency Related to Hospital Inpatient Quality?
Roxanne Andrews, Agency for Healthcare Research and Quality; Anika Hines, Truven Health Analytics; Ernest Moy, MD, MPH, Agency for Healthcare Research and Quality; Marguerite L. Barrett, MS, M.L. Barrett, Inc; Rosanna Coffey, PhD, Truven Health Analytics

Presenter: Roxanne Andrews, Ph.D., Center for Delivery, Organization, and Markets, Agency for Healthcare Research and Quality, roxanne.andrews@ahrq.hhs.gov

Research Objective: The role of primary language in access to health care has been well-documented. Fewer studies have examined the association of language barriers with quality and outcomes of care once access to healthcare is achieved. In the few studies that have been done, results are inconsistent. This study examines hospital care quality across language groups—English, Spanish, or languages of Asia and the Pacific Islands.

Study Design: We performed a cross-sectional analysis of hospital discharge records using data from the 2009 Healthcare Cost and Utilization Project’s (HCUP) California State Inpatient Databases (SID). The SID includes discharge abstracts with demographic and clinical information for all inpatient stays, regardless of payer. We included patients admitted to community, non-rehabilitative hospitals who self-reported their principal language. Using the Agency for Healthcare Research and Quality (AHRQ) Inpatient Quality Indicators (IQIs) and Patient Safety Indicators (PSIs), we calculated risk-adjusted inpatient mortality per 1,000 admissions for acute myocardial infarction (AMI), congestive heart failure (CHF), gastrointestinal (GI) hemorrhage, and stroke as well as obstetric traumas per 1,000 vaginal deliveries. We focused on IQIs and PSIs with the largest sample size to assure sufficient statistical power and reliability. We adjusted inpatient mortality for age, gender, age-gender interactions, severity, and mortality risk. Rates of obstetric trauma are age-adjusted. We compared rates across race/ethnicity, principal language, and race/ethnicity-language groups using two-sided t-tests.

Population Studied: 3,757,218 inpatients admitted to California’s hospitals in 2009, including 3,211,939 (85.5%) English-speaking patients; 474,267 (12.6%) Spanish-speaking patients; and 71,495 (1.9%) patients speaking languages of Asia or the Pacific Islands (API)

Principal Findings: Spanish-speaking inpatients had lower rates of mortality for CHF (18.47 versus 25.50; p<0.01), stroke (75.50 versus 82.30; p<0.05), and pneumonia (28.11 versus 33.68; p<0.01) as well as rates of obstetric trauma with (98.84 versus 120.91; p<0.01) and without instrumentation (18.71 versus 21.04; p<0.01) compared to English-speakers. Asian language speakers (19.20 versus 25.50; p<0.05) had lower rates of CHF inpatient mortality and higher rates of obstetric trauma (165.52 versus 120.91 with instrumentation; p<0.01 and 48.59 versus 21.04; p<0.01 without instrumentation) than English-speakers. Within ethnic groups, Spanish-speaking Hispanics had lower rates of pneumonia inpatient mortality than their English-speaking counterparts (28.19 versus 34.37; p<0.05), and higher rates of obstetric trauma among vaginal deliveries without instrumentation (18.59 versus 14.98; p<0.01).

Conclusions: In this study of California inpatients, non-English speakers were not at a higher risk for inpatient mortality for the selected study conditions compared to English-speakers. There were some apparent differences in pneumonia mortality and obstetric trauma between English and non-English speakers within ethnic groups. There are limitations of the findings that should be considered in future research including that discharge data have limited clinical content which could affect the accuracy of the risk adjustment.

Implications for Policy, Delivery, or Practice: Collection of "Preferred Language" in the electronic healthcare record is a requirement for the "Meaningful Use" incentive reimbursement set by CMS. Subsequently, more widespread collection of this information in hospital records is expected. The collection of patient language data may be particularly important for highlighting intra-ethnic group differences in inpatient mortality and adverse events and targeting interventions to address language barriers.

Racial and Rural Differences in Cervical Cancer Prevention and Control Practices
Swann Arp Adams, University of South Carolina; Jessica Bellinger, University of South Carolina; Alexa Gallagher, University of South Carolina; Jan Probst, University of South Carolina
**Presenters:** Jessica Bellinger, Ph.D., M.P.H., Postdoctoral Fellow, South Carolina Rural Health Research Center, University of South Carolina, bellingj@mailbox.sc.edu

**Research Objective:** Access to preventive services contributes to differences in cervical cancer screening, treatment, and survival. We examined access to advanced cervical cancer prevention technologies, including liquid-based Pap test cytology, HPV vaccination, and DNA testing among rural versus urban women.

**Study Design:** We conducted a cross-sectional study of 2006 - 2008 visit-level data from National Ambulatory Medical Care Survey (NAMCS) and National Hospital Ambulatory Medical Care Survey (NHAMCS). Data were linked to the 2009 Area Resource File (ARF) based on both provider and patient/visit location. Patient/visit and provider location were linked using state and county FIPS codes.

**Population Studied:** To examine the likelihood of receiving a liquid-based Pap test, the study population was limited to visits by female white and African American patients (9 – 70 years of age) with record of a Pap test. To examine the likelihood of receiving HPV DNA test, the study population was limited to visits for preventive screening or routine general exams rather than visits for new problems or pre/post-surgery. Records with missing information were excluded.

To examine cervical cancer screening practices, patients were categorized by Pap test cytology (liquid-based, conventional, or unspecified) and an HPV DNA test during their visit (yes/no). Race/ethnicity was classified as white or black/African American. Location was examined based on patient’s county of residence and physician practice site.

SAS-callable SUDAAN was used to account for complex sampling required weighted analysis. Descriptive statistics and bivariate comparisons were computed using chi square tests. Analyses incorporating restricted data (environmental and geographic variables and physician characteristics) were conducted at the National Center for Health Statistics Research Data Center.

**Principal Findings:** No significant differences were observed for Pap test cytology by patient residence (urban versus rural; p=0.21) or for receipt of liquid Pap testing between white and African-American women residing in urban or rural counties (p=0.35).

A significantly higher proportion of women living in rural counties (69.6%) received liquid based Pap testing in hospital outpatient settings than women in urban counties (39%; p=0.02). A significantly higher proportion of women residing in urban counties received HPV DNA testing versus women residing in rural counties (10% versus 3.3%, respectively). Report of HPV vaccination was too low during the study period to permit stable estimates for rural women, so no rural-urban comparisons can be offered. Differences in provider reimbursement were noted with higher proportions of publicly insured patients in rural practices than urban practices (p<0.01).

**Conclusions:** Women residing in rural counties did not differ from urban in conventional or liquid-based Pap test cytology; however, rural women were less likely to receive HPV DNA testing. No racial differences were detected. More research is needed to determine if observed differences are the result of provider or patient barriers and acceptability.

**Implications for Policy, Delivery, or Practice:** The proportion of visits by rural residents for preventive services was lower than among their urban counterparts. Increased coverage and expanded access to cervical cancer preventive services may increase uptake of innovative preventive services, particularly liquid-based cytology and HPV DNA testing.

**Decreasing Colorectal Cancer Screening Inequity? The Effect of an Advanced Population Management System**

Seth Berkowitz, Massachusetts General Hospital; Jeffrey M. Ashburner, MPH, Massachusetts General Hospital; Yuchiao Chang, PhD, Massachusetts General Hospital; Adrian H. Zai, MD PhD MPH, Massachusetts General Hospital; Sanja Percac-Lima, MD PhD, Massachusetts General Hospital; Steven J. Atlas, MD MPH, Massachusetts General Hospital

**Presenter:** Seth Berkowitz, M.D., Fellow in General Medicine and Primary Care, General Medicine, Massachusetts General Hospital, saberkowitz@partners.org

**Research Objective:** Compared to patients with greater than high school (>HS) educational attainment, patients with a high school diploma or less (=HS) have lower colorectal cancer screening rates. A significantly higher proportion of patients with education level (9%) were observed to receive liquid-based Pap testing in hospital outpatient settings than women in urban counties (39%; p=0.02). A significantly higher proportion of women residing in urban counties received HPV DNA testing versus women residing in rural counties (10% versus 3.3%, respectively). Report of HPV vaccination was too low during the study period to permit stable estimates for rural women, so no rural-urban comparisons can be offered. Differences in provider reimbursement were noted with higher proportions of publicly insured patients in rural practices than urban practices (p<0.01).

**Conclusions:** Women residing in rural counties did not differ from urban in conventional or liquid-based Pap test cytology; however, rural women were less likely to receive HPV DNA testing. No racial differences were detected. More research is needed to determine if observed differences are the result of provider or patient barriers and acceptability.

**Implications for Policy, Delivery, or Practice:** The proportion of visits by rural residents for preventive services was lower than among their urban counterparts. Increased coverage and expanded access to cervical cancer preventive services may increase uptake of innovative preventive services, particularly liquid-based cytology and HPV DNA testing.

(CRC) screening rates and 50% greater risk of CRC mortality. Population management strategies, facilitated by advanced health information technology, are increasingly used to improve screening rates, but often do not specifically target health inequities. We evaluated whether such a system might still decrease educational disparities in CRC screening.

**Study Design:** From June 15, 2011 to June 14, 2012 we utilized TopCare (Technology for Optimizing Population Care in a Resource-limited Environment) to identify and manage all patients eligible for CRC screening within an 18-practice academic primary care network. Patients overdue for screening received interventions to promote completion including notification of primary care providers, reminder letters, and listing with practice delegates who could schedule tests and visits. Practices were randomized to one of two versions of TopCare, but because there was not a differential effect on outcomes by version (test for interaction was non-significant), we report pooled results. Our primary outcome was CRC screening completion, stratified by patient educational attainment (=HS vs. >HS), a correlate of low socioeconomic status. We performed unadjusted comparisons using chi-square and McNemar’s tests. A logistic regression model was used to compare CRC screening completion among patients with complete follow-up. A Cox regression model was used to evaluate time-to-screening completion among all patients overdue for screening at any time during the study period.

**Population Studied:** Men and women age 52-75 without prior total colectomy.

**Principal Findings:** Among 40,454 patients in 18 practice sites eligible for CRC screening over the study period, 75% had >HS educational attainment. =HS patients were more likely to be non-white, non-English speaking, and have Medicare, Medicaid, or no insurance (p <.001 for all comparisons). Prior to TopCare implementation, 73.0% of =HS patients had completed CRC screening, compared to 80.6% of >HS (p <.001). At the end of the study period, screening completion increased for both groups (+3.2% for =HS, p <.001; + 2.5% for >HS, p <.001). However, a significant disparity in screening completion between =HS and >HS remained (76.2% vs. 83.1%, p <.001). In a logistic regression model accounting for physician/practice clustering and adjusting for age, gender, race/ethnicity, language, insurance, and TopCare version, =HS was significantly associated with lower CRC screening completion (adjusted completion rate 76.8% in =HS vs. 79.0% in >HS, p <.001). In a multivariable Cox regression model among 11,976 patients overdue for screening, =HS was associated with prolonged time to screening completion (HR 0.89, 95% CI 0.81-0.98, adjusted for same covariates as above).

**Conclusions:** Despite the promise of population management systems to increase the overall use of preventive services, CRC screening disparities did not decrease over a 1-year follow-up period among patients with low educational attainment.

**Implications for Policy, Delivery, or Practice:** Population management approaches that do not specifically address disparities may not improve them, and if less effective in low education patients, may instead widen disparities over time. Future strategies should specifically address causes of CRC screening disparities in order to improve health equity.

**The Distribution of Public Spending for Health Care in the United States**

Didem Bernard, Agency for Healthcare Research and Quality; Thomas Selden, AHRQ; Yuri Pylypchuk, Social & Scientific Systems, INC

**Presenter:** Didem Bernard, Ph.D., Senior Economist, Center for Financing, Access, and Cost Trends, Agency for Healthcare Research and Quality, didem.bernard@ahrq.hhs.gov

**Research Objective:** U.S. health care spending in 2011 was $2.7 trillion or 17.9% of GDP. This study informs the debate over public spending on health care by combining estimates from the National Health Expenditure Accounts and data from the Medical Expenditure Panel Survey to answer two questions. First, what is the overall percentage of health care paid for by the public sector and how has this changed over time? Second, what is the current incidence of public spending by age, income, and health status?

**Study Design:** Because no single data source provides all of this information, we use household and employer survey data, national expenditure benchmarks, and microsimulation modeling. For the detailed incidence analysis, we align MEPS by type of service and source of payment with 2007 NHEA benchmarks. (Bernard, Cowan, Selden, Liming, Catlin &
Heffler, 2012, MMRR). Next, we allocate amounts in NHEA that were outside the scope of MEPS such as administrative costs, DSH payments, research and investment. Finally, we estimate a comprehensive array of tax expenditures. (Bernard, Selden and Plypchuk, 2013)

**Population Studied:** US population in 2007

**Principal Findings:** Combining public outlays with implicit public spending through tax expenditures, the public share of total health spending increased from 31.2% in 1960 to 58.7% in 2007 (the year of our incidence analysis) and to 63.0% in 2012 (projected). Tax expenditures as a percentage of health care spending are approximately 13% at present. Among the non-institutionalized population in 2007, the public sector’s role is largest for seniors for whom 68.0% of total spending was paid for by the public, versus 59.3% for children and 49.2% for adults age 19-64. Not only do adults 19-64 have the smallest public percentage, but also public outlays in this group are highly concentrated. Non-elderly adults with disabilities consumed 81.1% of all Medicaid/CHIP and Medicare, despite comprising only 10.3% of the 19-64 age group. With respect to incidence of public expenditures by income level, lower income groups benefited most from Medicaid/CHIP spending. In contrast, the remaining categories of public health care outlays were somewhat more evenly distributed, and tax subsidies strongly favored high-income families. Overall, public spending accounted for 81.8% of total health care spending among those under 100 percent of FPL and for 42.3% of total spending among those over 400 percent of FPL. However, we find that all poverty groups continue to share in the benefits of public spending. Even among families with incomes above 400% of FPL, public spending accounted for over two-fifths of total spending.

**Conclusions:** Seniors benefit most from public spending. When tax expenditures are taken into account, all poverty groups benefit from public spending.

**Implications for Policy, Delivery, or Practice:** Our findings offer a useful backdrop for the ongoing debates over the ACA’s likely impacts on the level and incidence of outlays (Medicaid/CHIP and Medicare), exchange subsidies, and tax expenditures. Our findings also offer a useful baseline for further steps the country might take on entitlements and tax policy to ensure long-term fiscal stability.

**Moderators of Access and Mammography Utilization in Black and White Women Responding to the 2008 Behavioral Risk Factor Surveillance Survey**

Parker McDill, Graduate School of Nursing, Uniformed Services University; Sandra Bibb, Uniformed Services University of the Health Sciences; Cara Olsen, Biostatistics Consulting Center, Uniformed Services University

**Presenter:** Sandra Bibb, D.N.Sc., Associate Professor, School of Nursing, Uniformed Services University of the Health Sciences, sbibb@usuhs.mil

**Research Objective:** To determine the extent to which multiple determinants of health, grouped as population characteristics, health status, and health risks and behaviors, moderate access to care and impact utilization of mammography in black and white women age 40 years and older, responding to the 2008 Behavioral Risk Factor Surveillance System (BRFSS ) Survey.

**Study Design:** The research design was descriptive, exploratory. Analyses were conducted on the created sample and on subsets of the sample to include black women, white women, and women age 50 to 74. Hierarchical logistic regression was used to explore the extent to which the independent variables and the hypothesized moderating factors effected utilization of mammography in black and white women. All moderator variables determined to have a statistically significant relationship (p < .05) with the dependent variable (mammography utilization) were included in the moderator models. A total of three hierarchical logistic regressions were conducted for the main analysis and each subgroup; access-population characteristics; access-health status; and access-health risks and behaviors. When a statistically significant improvement in the fit of the regression model was achieved by adding the interaction terms, an overall moderator effect was determined to be present. Individual moderating factors were identified by their statistically significant interactions with one or more access variables.

**Population Studied:** Existing data from women 40 and older who self-identified their preferred race as black or white on the 2008 BRFSS survey.

**Principal Findings:** In both the main (40 and older) and subgroup (age 50 to 74) analyses for
Principal Findings: Participants were inner-city Blacks living in a midsize city in a Midwestern state and were recruited through a community-based organization that addresses health and social needs of African Americans.

Principal Findings: Participants ranged in age from 19 to 95 years (M=43.04, SD=6.14). Fifty-four percent were female; 79%
had less than a college degree; the median income was $20,000 to $29,000 and 27% were unemployed. Forty-three percent had a chronic disease. The most prevalent health conditions were hypertension, obesity, asthma, diabetes, and heart disease. The participants displayed a moderate knowledge level of genetics (Mean score=74%). Participants expected genetics information to be stored on computers but anticipated that the government will be unable to protect the privacy of citizens given collection of such sensitive data. Three-quarters anticipated that insurance companies will want to see genetic tests results before the cost for insurance is set. Most had high expectations about the increasing use of genetics in identifying risks, prevention, treatment and personalized healthcare. In multivariate analyses, knowledge and concerns for abuse of genetic information were significantly associated with negative attitudes towards genetic testing and research. 

Conclusions: Although participants in this study anticipated negative consequences of genetics developments, an increase in their knowledge of medical genetics could decrease the negative attitude when participants are assured there will be no abuse of the genetic information. These findings suggest that recruitment and retention of African Americans in genetics studies should address potential concerns about their knowledge, expectations, and use of genetic information.

Implications for Policy, Delivery, or Practice: Geneticists, public health professionals and policy makers can fill the gaps by developing educational programs about genetics innovations in medicine taking into account pre-existing lay knowledge, views and expectations and attitudes of Blacks. Further, there is critical need to sustain engagement with inner-city Black communities with educational programs about genetics and chronic diseases.

Nguyen, University of Wisconsin-Milwaukee, College of Nursing

Presenter: Aaron Buseh, Ph.D., M.P.H., Associate Professor, College of Nursing, University of Wisconsin, Milwaukee, aaronbg@uwm.edu

Research Objective: African Americans continue to bear a disproportionate burden of HIV/AIDS. Black men represent almost one-third of all new HIV infections in the U.S. Understanding their experiences with disclosure of HIV status will inform both prevention and treatment interventions in the African American community. The purpose of this qualitative study was to explore the issue of disclosure with HIV positive African American men residing in a mid-sized Midwestern city.

Study Design: Fifty African American men (n = 50) participated in in-depth interviews about their experiences living with HIV. Participants ranged in age from 24 - 57 years; mean age = 43.98, SD = 7.59. Time since HIV diagnosis ranged from 3 months to 26 years; mean time = 12.5 years, SD = 7.2. Data were analyzed thematically.

Population Studied: Participants were recruited through a community-based organization in an urban setting from a Midwestern state. A snowball sampling technique was used to obtain a sample of African American men (18 years or older) who self-reported as being HIV-infected.

Principal Findings: Disclosure of HIV status posed a major dialectical struggle between the need to "unburden" the HIV, and the need to protect essential economic and social resources. Balancing such opposing needs cost men energy, peace, authenticity, happiness, and access to health care. For those who were able to disclose widely, the emancipation they experienced fueled public activism to decrease HIV stigma.

Conclusions: In this era of test and treat, disclosure of HIV status is even more important
for individual health and for broader societal prevention through early treatment efforts. Yet, disclosure remains problematic for HIV-infected African American men. It is imperative that community, family, and work environments be made safer so that HIV positive status holds no power over dignity, confidence and belonging.

**Implications for Policy, Delivery, or Practice:**
Results from this study have implications for healthcare providers working with urban HIV-infected Black males. Eliciting illness experiences of African American men living with HIV/AIDS, from their point of view, is an excellent starting point for health professionals as they try to gain a comprehensive history of what their patients deal with every day. Subjective illness as gathered from participants in this study can be used in psychology and psychiatric settings, medical, nursing, and other healthcare academic/educational settings and disciplines with the goal of training future healthcare professionals to provide care with empathy using a humanistic approach.

**Censored Mental Health Disparities: Methodology’s Influence on Estimating of Disparities in the Adequacy Mental Health**

Adam Carle, Cincinnati Children's Hospital Medical Center; Kellana Hindert, M.A., Cincinnati Children's Hospital Medical Center; Ben Le Cook, Ph.D., Harvard University; Chih-Nan Chen, Ph.D., Harvard University

**Presenter:** Adam Carle, Ph.D., M.A., Assistant Professor of Pediatrics, University of Cincinnati School of Medicine, Cincinnati Children's Hospital Medical Center, adam.carle@cchmc.org

**Research Objective:** A critical need exists to address disparities in the persistence, severity, and disease burden of mental health disorders among Blacks, Hispanics and Whites. Mental health service use is more disparate among minorities than in many other areas of care. The ability to understand and detect what drives these disparities will allow policymakers to take action to reduce gaps and make informed, rational planning decisions. Differences in the quality of care (e.g., adequacy) minorities receive may account for some disparities. Adequate care in the mental health area has been defined as eight or more mental health care visits or four or more visits with a prescription fill. Given the definition's longitudinal nature, one would ideally observe individuals across time. However, methodological challenges exist when analyzing adequacy of care. Individuals may have begun receiving care before the study's start and (similarly) may continue to receive care following the study's end. This “censoring” may result in apparent poor care, rather than truly poor care. To date, little research has addressed how to best handle censoring of this sort. Thus, we sought to assess different methods of handling censored data on conclusions regarding disparities in adequate care in mental health service usage.

**Study Design:** The Medical Expenditure Panel Survey (MEPS) constitutes a set of large-scale surveys of families and individuals, their medical providers, and employers across the United States. The MEPS is the most complete source of data on the cost and use of health care and health insurance coverage in the US. We used two year longitudinal panel data from 2004-2008. We evaluated differences in conclusions when implementing a two-part negative binomial model and a naïve method that does not account for censoring, and a naïve method that dropped censored cases. In addition, we examined the impact of different ways of coding censoring.

**Population Studied:** Adults with probable depressive disorder identified using the PHQ-2 checklist (score >2) and adults with severe psychological distress identified using the K6 survey (score >13).

**Principal Findings:** Though technique impacted estimates, generally across methods Blacks and Latinos had less initiation and adequacy of care (compared to Whites). Black and Latino episodes were shorter and had fewer psychotropic drug fills. Black episodes had a greater proportion of specialist visits while Latino episodes had a greater proportion of PCP visits. Blacks terminated care more frequently in acute care settings. There is also evidence that adequate care varies by income. However, despite similarity in the direction of conclusion, the size of the conclusion differed across methods.

**Conclusions:** Estimation technique influences disparities conclusions. We discuss how the specific estimation technique that one chooses depends on aspects of the studied predictors.
and outcomes. We also discuss our work’s substantive implications.

**Implications for Policy, Delivery, or Practice:** Differences in initiation influenced disparities in adequate care, supporting the need for policies that improve access. Many episodes consisted only of psychotropic drug fills, indicating inadequate medication guidance. Blacks’ greater termination in acute care settings raises concern of inadequate monitoring. Blacks’ higher rate of specialist use opposes previous research and requires future investigation.

**Racial and Ethnic Disparities in Utilization of Physical Therapy among Working Age Adults with Chronic Low Back Pain**

Olivia Carter- Pokras, School of Public Health; Jie Chen, Department of Health Services Administration, School of Public Health, University of Maryland College Park

**Presenter:** Olivia Carter- Pokras, MHS, PhD, Associate Professor, Department of Epidemiology and Biostatistics, School of Public Health, opokras@umd.edu

**Research Objective:** To examine cost-effectiveness of physical therapy among working age adults with chronic low back pain, and identify racial and ethnic disparities in utilization of physical therapy.

**Study Design:** We used data from the 2000-2010 Medical Expenditure Panel Survey. An initial analysis implemented a means comparison of the likelihood of receiving any physical therapy by race and ethnicity (Whites, African Americans, and Latinos). Subsequently we implemented the Blinder-Oaxaca decomposition technique to identify factors associated with the racial and ethnic disparities in receiving the physical therapy. Longitudinal analyses were employed to estimate the impact of physical therapy on other health care utilization.

**Population Studied:** Working age adults (18-64 years old), with diagnosis of back pain (ICD9=724), who self-reported having pain for more than 12 months. Our sample included 5,019 Whites, 1,085 African Americans, and 1,288 Latinos.

**Principal Findings:** Descriptive statistics showed that on average, 16% of working age Whites with chronic low back pain had received physical therapy. This percentage was significantly higher than that for African Americans (12%), and Latinos (14%). The decomposition results showed that poverty (measured by lower family income) was the major reason associated with disparities among Whites vs. African Americans. Fewer years of education and less health insurance coverage were the two main reasons associated with disparities among Whites vs. Latinos. Longitudinal analyses suggest that receipt of physical therapy can reduce prescription drug use for low back pain.

**Conclusions:** These findings directly address gaps in the literature identified by the Institute of Medicine’s report “Relieving Pain in America,” and add disparities in referrals to physical therapy to the existing literature regarding persistent disparities in pain treatment.

**Implications for Policy, Delivery, or Practice:** These findings have important cost-saving implications for implementation of the Affordable Care Act, particularly treatment of workers with low back pain. In addition to reducing prescription drug use found in our study, moderate evidence exists that post-treatment exercises can reduce both number and rate of back pain recurrences (Choi, Verbeek, Tam, Jiang, 2011). Disparities in physical therapy referrals may therefore partly explain higher levels of occupational disability for African-American worker’s compensation claimants with low back pain compared to whites (Chibnall & Tait 2009).

**Patient Navigation for Asian Americans: A Systematic Review**

Mei Chung, Tufts Medical Center; Samantha Berger, BS, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center; Susan Koch-Weser, ScM, ScD, Department of Public Health and Community Medicine, Tufts University School of Medicine; Carolyn L. Rubin, EdD, MA, Tufts Clinical and Translational Science Institute (CTSI), Tufts Medical Center; Tanya Bernstein, MPH, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center; Susan K. Parsons, MD, MRP, Institute for Clinical Research and Health Policy Studies, Tufts Medical Center

**Presenter:** Mei Chung, PhD, MPH, Assistant Professor of Medicine, Institute for Clinical Research and Health Policy Studies, Tufts
Research Objective: To evaluate the published literature on patient navigation programs serving Asian communities in the U.S. regarding program activities, navigator roles, barriers to care, and program effectiveness outcomes.

Study Design: A systematic review was conducted and a comprehensive search strategy was developed through an iterative process. The database search was conducted on MEDLINE® (through January 2012), Cochrane Central Register of Controlled Trials (through last quarter of 2011), and Global Health (1973 to December 2011). We operationalized the definition of a PN intervention to establish our study eligibility criteria. Studies were included if the program provided an active navigation component, and were excluded if the programs only provided education support or group-based support.

Population Studied: Our search was not restricted to specific Asian population, disease or cancer type. Qualifying studies in this systematic review enrolled Asian Americans of Chinese, Vietnamese, Korean, Cambodian, or Laotian origin.

Principal Findings: The search identified 1,701 citations, and 98 full-text articles were evaluated by 2 investigators for eligibility. Only 12 unique PN programs met our criteria to be included. The majority of rejected articles were not relevant, only included background information or consisted of an education only intervention. The 12 articles reporting results of PN programs focused on breast, cervical, or colorectal cancer screening and detection, and enrolled more than 4,000 Asian Americans in total. All 12 programs documented positive changes, including improved uptake of screening tests, examinations, or other appropriate preventive behavior. Patient navigator job titles varied; the most commonly used were lay health worker, patient navigator, and outreach worker. Navigators assisted patients through scheduling, interpretation, transportation, counseling, and educational activities. Barriers identified during formative research from the programs included cancer knowledge, socioeconomic status, culture, language, gender, and medical systems. Four studies identified residual barriers of cost, gender, cancer knowledge, and medical process despite PN programs. Improvements in cancer screening rates ranged from 7% to 64% after the implementation of the PN programs with greater increases in breast or cervical cancer screening than colorectal screening (reported in 8 studies). Of these, five studies showed that each PN program was effective in increasing the cancer screening rate as compared to the control group (s) (RR [95%CI] ranged from 1.31 [0.99, 1.74] to 53 [7.56, 376]).

Conclusions: Only a limited number of studies were identified to address the impact of PN in Asian Americans, and these focused on cancer screening. Nevertheless, the success of the 12 programs illustrates the value of a multimodal approach to navigation, combining education, logistical support, and counseling. Further, these programs were culturally sensitive, as reflected in the choice of gender, ethnicity, and language of program personnel to overcome barriers to care that have caused health disparities in Asian populations.

Implications for Policy, Delivery, or Practice: This systematic review identified only 12 published studies of successful PN programs for Asian Americans. Further research is needed to understand how culturally sensitive PN programs can be used to enhance cancer care across the entire continuum from detection to treatment to survivorship for this vulnerable population.

Socioeconomic Status and Demographic Disparities in Utilizing Dilated Eye Exams
Delawnia Comer-Hagans, Governors State University; Dr. Ning Lu, Governors State University; Dr. Zo Ramamonjiarivelo, Governors State University

Presenter: Delawnia Comer-Hagans, Ph.D., Assistant Professor, Health Administration, Governors State University, dcomer-hagans@govst.edu

Research Objective: As the number of people with diabetes rises in the U.S., the CDC projects that the number of adults with diabetic retinopathy will double by the year 2050. National Eye Institute recommends that diabetics be monitored regularly by their ophthalmologist to prevent vision loss. The purpose of our study is to determine the rates of dilated eye exam use among diabetics, to examine the trend of dilated eye exam use in the past 10 years between 2000 and 2010, and to identify differences in dilated eye exam use by medical center.
demographic, socioeconomic, and healthcare access related factors.

**Study Design:** Secondary data analysis of the 2000 and 2010 Behavioral Risk Factor Surveillance System (BRFSS) of diabetic individuals. Univariate analysis was used to describe the demographic, socioeconomic, and healthcare access related variables in the study followed by binary logistic regressions. The dependent variable is utilization of dilated eye exams within the past year (1=yes, 0=no). The independent variable of interest, race, is categorical (White, Black, and other).

**Population Studied:** Diabetic adults who are 18 years of age and older for the years 2000 (N=11,647) and 2010 (N=57,480).

**Principal Findings:** The target of 70% of diabetics receiving dilated eye exams was reached for Whites (73%, N=4,935), and Blacks (72%, N=1,013), but not for other races (61% of other races, N=1,220) in 2000. The target of 76% of diabetics receiving dilated eye exams was not reach for Whites (70%, N=17,387), Blacks (71%, N=4,084), or other races (63%, N=3,327) in 2010. The results of logistic regression analysis of both years 2000 and 2010 data revealed that individuals who were told by a healthcare provider that diabetes affected their eyes, had health insurance, had a checkup within the past year, and had diabetes education are significantly more likely to receive a dilated eye exam than their counterparts at p<0.05. In addition, age is significantly related to the receipt of a dilated eye exam. Those who are older than 45, are more likely to receive a dilated eye exam than younger individuals. Those who reported that they were unable to see a doctor due to cost were significantly less likely to receive a dilated eye exam.

**Conclusions:** The target set in 2010 for diabetics receiving dilated eye exams was not reached by any race group. Our study indicated that individuals who had limited access to healthcare due to cost are less likely to receive dilated eye exams. Being told that diabetes can impact an eye condition, a yearly health checkup, diabetes education, health insurance as well as higher education and higher income, increase the odds of receiving a dilated eye exam.

**Implications for Policy, Delivery, or Practice:** Identifying individuals at risk by SES and demographics will help policy makers and health professionals to develop policy or programs promoting dilated eye exams among the population at risk. Removing financial barriers might be helpful in promoting utilization in dilated eye exams, one of the major preventive measures of diabetes complications.

**Relationship between Self-Assessed and Tested Non-English Language Proficiency among Primary Care Providers**

Lisa Diamond, Memorial Sloan-Kettering Cancer Center; Sukyung Chung, Palo Alto Medical Foundation Research Institute; Warren Ferguson, University of Massachusetts Medical School; Elizabeth Jacobs, University of Wisconsin - Madison; Francesca Gany, Memorial Sloan-Kettering Cancer Center

**Presenter:** Lisa Diamond, MD, MPH, Assistant Attending Physician, Immigrant Health and Cancer Disparities, Memorial Sloan-Kettering Cancer Center; diamondl@mskcc.org

**Research Objective:** To evaluate the accuracy of a structured self-assessment of non-English language proficiency compared to a validated oral proficiency interview for clinicians.

**Study Design:** We asked clinicians with varying self-reported levels of proficiency in Cantonese, Mandarin, French, Portuguese, Spanish, and Vietnamese (the most common languages spoken by clinicians and patients at the study sites) to participate. Clinicians were recruited via email invitation. Participants completed a brief survey which asked them to self-assess their language proficiencies, followed by instructions on accessing a validated method for assessing their oral proficiency. Upon completion of the oral proficiency interview, participants were given a $50 gift card.

**Population Studied:** The study was conducted with clinicians in two settings, the Palo Alto Medical Foundation (PAMF) and several Massachusetts Community Health Centers (MA CHC).

**Principal Findings:** Sixteen PCPs in California and 51 in Massachusetts participated in the study. Spanish was the most common language tested (79%), followed by Cantonese, Mandarin, French, Portuguese, and Vietnamese. The respondents self-reported their proficiency level as “Excellent” 9% of the time, 24% rated “Very Good,” 46% “Good,” 18% “Fair,” and 3% rated “Poor” proficiency. The average CCLA score was 76/100. There was a positive correlation between self-reported ILR scale and CCLA score (rho=0.49, p<0.001). Respondents who
self-reported “Excellent” on the ILR scored an average of 87 on the CCLA. Respondents who self-reported “Poor” scored an average of 34 and those who self-reported “Fair” scored an average of 64. Scores for participants who self-rated as “Good” or “Very Good” were similar (78 vs. 80). The variance in CCLA scores was wider in the middle categories (“Good” or “Very good”) than in the low or high ILR categories (p=0.003).

**Conclusions:** Self-reporting of non-English language proficiency using the ILR correlates to tested language proficiency, particularly on the low and high ends of the self-rating scale. Participants who self-report in the middle of the scale may require additional testing. Further research needs to be done to identify the characteristics of PCP whose self-reported non-English proficiency levels are inaccurate and, thus, require proficiency testing.

**Implications for Policy, Delivery, or Practice:**
As language concordance has been shown to improve healthcare quality, it is essential that health care organizations and providers know how to accurately measure clinicians’ non-English language proficiency. There is a need for further research to identify the characteristics of PCPs whose self-assessed non-English proficiency levels are inaccurate and proficiency levels are inaccurate and, thus, require proficiency testing. It makes sense that true language concordance between LEP patients and clinicians would be beneficial but it is not known what level of non-English language proficiency is sufficient or necessary to provide safe and effective care.

**Geographic Distribution of Radical Hysterectomies and Gynecologic Oncologists in the United States**
Michaela Dinan, Duke Clinical Research Institute; Lesley Curtis, Duke Clinical Research Institute; Evan Meyers, Duke University Medical Center; Laura Havrilsky, Duke University Medical Center

**Presenter:** Michaela Dinan, Ph.D., B.S., Fellow, Center for Clinical and Genetic Economics, Duke Clinical Research Institute, michaela.dinan@duke.edu

**Research Objective:** Investigate the geographic distribution of gynecologic oncologist practice locations in relation to a surgical procedure recommended to be performed by gynecologic oncologists, specifically oophorectomy for women with a diagnosis of ovarian cancer.

**Study Design:** Retrospective cross-sectional study of state-based rates of inpatient oophorectomy performed on women with a diagnosis of ovarian cancer between 2000-2007 compared to 2007 practice locations of gynecologic oncologists provided by the Society of Clinical Gynecologic Oncologists.

**Population Studied:** Women with a diagnosis of ovarian cancer within the 2000-2007 Nationwide Inpatient Sample (NIS) who hand an oophorectomy and the 2007 practice locations of gynecologic oncologists provided by the Society of Clinical Gynecologic Oncologists.

**Principal Findings:** A total 26438 oncologic oophorectomy cases during the 8 year study period were identified for analysis. Gynecologic oncologist practice locations were concentrated in California, Texas, Florida, and in the Northeast and East (Ohio, Pennsylvania, New York, Virginia, and North Carolina). The highest ratio of oophorectomy volume to gynecologic oncologist availability was observed in the west (Utah, California, and Oregon), whereas the lowest volume per specialist was found in the Northeast (Maine, PA, Vermont). Rates of gynecologic oncologists relative to the population were highest in the Northeast. Overall rates of oophorectomy and gynecologic oncologists were highly correlated with the number of adult females within a state, but also exhibited significant regional variation.

**Conclusions:** Previous studies have documented substantial disparities in women who undergo initial surgical management by gynecologic oncologists as compared with general gynecologists or surgeons. In this study, we found that substantial geographic variability exists in the rate of state-based gynecologic oncologist surgical demand as compared to gynecologic oncologist availability. Future research is warranted to characterize the relationship between specialist supply and demand for specialist services and its potential to impact health disparities in ovarian cancer.

**Implications for Policy, Delivery, or Practice:** Ovarian cancer is the 5th leading cause of mortality from cancer in American women. For women diagnosed with ovarian cancer, initial surgical management by a gynecologic oncologist has been associated with increased survival and reduced morbidity. Geographic distribution of gynecologic oncologists in relation...
to women requiring gynecologic oncologic services may impact access to optimal ovarian cancer care.

**Dual Eligibility With Medicare: A Dual Problem For Veterans With Traumatic Brain Injury?**

Clara Dismuke, US Department of Veterans Affairs; Leonard E. Egede MD MS, Ralph H. Johnson VAMC and Medical University of South Carolina

**Presenter:** Clara Dismuke, Ph.D., Research Health Scientist, DHAP, US Department of Veterans Affairs, dismuke@musc.edu

**Research Objective:** There is evidence that dual eligibility (VA and Medicare beneficiary status) is associated with higher mortality rates among Veterans with colon cancer, stroke and multiple disease conditions. There is also evidence that the federal government is spending a substantial and increasing amount of potentially duplicative funds in the VA and Medicare. Traumatic Brain Injury (TBI) is a priority diagnosis in the VA. We examined the association of dual eligibility (VA and Medicare beneficiary status) with clinical (mortality) and economic (outpatient visit utilization) outcomes among Veterans diagnosed with Traumatic Brain Injury (TBI).

**Study Design:** We estimated the association of dual eligibility with mortality and VA outpatient visit utilization based on a national sample of 14,686 Veterans clinically diagnosed with TBI as of January 1, 2006 and followed for mortality until December 31, 2010 or death. We estimated a Cox model to examine the association of dual eligibility with mortality. We estimated a Poisson count model to examine the association of dual eligibility with the number of VA outpatient visits utilized in 2006. We adjusted for age, gender, race, marital status, rural residence, percent service connectedness, co-pay status, qualifying diagnosis code, and individual VA facility effect in both models and for months of survival in the Poisson model.

**Population Studied:** We identified all Veterans clinically diagnosed with TBI in 2006 based on VA criteria for ICD-9-CM codes: 800.xx — Fracture of the vault of skull, 801.xx — Fracture of the base of skull, 803.xx — Other and unqualified skull fractures, 804.xx — Multiple fractures involving skull or face with other bones, 850.xx — Concussion including commotio cerebri, 851.xx—Cerebral laceration and contusion, 852.xx — Subarachnoid, subdural, epidural, and extramural hemorrhage following injury, 853.xx 853.1 — Other unspecified intracranial hemorrhage following injury, 854.xx — Intracranial injury of other unspecified nature, or a patient episode with a V57.xx and TBI secondary diagnosis code from the list above or 310.2-Post-Concussion Syndrome, 905.0- Late Effect of fracture of skull and face bones, 907.0- Late effect of intracranial injury without mention of skull fracture.

**Principal Findings:** In a fully adjusted Cox survival model, we found that dual eligibility was associated with 53% (P<0.05) higher mortality relative to not having dual eligibility. In a fully adjusted Poisson model which included the clinical outcome (survival), we also found that dual eligibility was associated with a 5.2% higher rate of outpatient visit utilization.

**Conclusions:** We provide preliminary evidence that dual eligibility of VA and Medicare is associated with both worse clinical and economic outcomes among Veterans diagnosed with TBI. Possible explanations may include a lack of care coordination among VA and Medicare financed civilian providers, especially in a cognitively impaired population.

**Implications for Policy, Delivery, or Practice:** Our results suggest the need for further study to confirm whether these findings are short term or long term. Whatever the time frame may be, our results certainly highlight the need for interventions to improve care coordination between the VA and Medicare financed civilian providers for this cognitively impaired population of Veterans.

**Funding Source(s):** VA

**Latest USPSTF Updates in Screening Mammography Guidelines have had Minimal Impacts on Practice**

Martey Dodoo, Harvey L Neiman Health Policy Institute; Richard Duszak Jr, Harvey L Neiman Health Policy Institute; Geraldine B McGinty, NRAD Medical Associates, PC; Danny R. Hughes, Harvey L Neiman Health Policy Institute

**Presenter:** Martey Dodoo, Ph.D., Senior Research Fellow, Harvey L Neiman Health Policy Institute, mdodoo@acr.org
**Research Objective:** Based on a recently published comprehensive classification scheme for investigating “repeat testing” in medical imaging, we did the following: (1) Studied screening mammography rates (example of repeat testing) for Medicare beneficiaries; (2) Determined if the much heralded 2009 revisions in USPSTF breast screening guidelines have had any impacts on screening intervals; and (3) Investigated any variations in screening mammography rates and intervals due to geography of beneficiaries’ residence, age, race or ethnicity.

**Study Design:** Used the 5% national sample of Medicare beneficiary claims data (Limited Data Set) for the population of female elderly beneficiaries, 66 to 97 years old, (excluding new enrollees 65 years old and those above 97 years old). We selected beneficiaries enrolled continuously in Medicare and alive all 3 years in each of 2 periods: 2004–2006, and 2009–2011. These periods are approximately pre-post of the 2009 USPSTF breast screening guidelines which revised screening intervals from 12 to 24 months.

We compared average screening rates and screening intervals in the 2 periods for two cohorts defined as those that had screening mammograms in 2004 and 2009 respectively using interrupted time-series analysis methods. Screening mammography was identified as: HPCSC codes = "76092" (in 2004) or "77057" (in 2009-2011) or "G0202", and CPT diagnosis code = "V76.12". We undertook the analysis using SAS/ETS and JMP software.

**Principal Findings:** There were 1,074,781 beneficiaries in our 2004-2006 study population, and 860,846 in our 2009-2011 population. Average screening mammography rates were 51.1% in 2004-2006 and did not improve significantly in 2009-2011 (52.3%). Repeat screening intervals which were uni-modal in 2004-2005 and averaged 15.7 months, became mostly bi-modal but averaged 14.9 months in 2009-2010. During both time periods, screening intervals were uni-modal for whites and 66-69 year olds, but bi-modal for blacks and 70-97 year olds, and did not vary significantly between the 2 periods and by geography.

Preliminary findings from the interrupted time series analysis identified some seasonality in screening and confirmed that the latest USPSTF guidelines had minimal impact on screening intervals.

**Conclusions:** Screening mammography practice did not change significantly after the changes in the 2009 USPSTF breast screening guidelines. Screening intervals are still mostly 12 months and screening rates are 51 to 52%.

**Implications for Policy, Delivery, or Practice:** The 2009 USPSTF breast cancer screening guidelines disquieted and confused many patients and clinicians. Many clinician societies did not accept the revisions. As a result, patient and clinician practice has remained practically unchanged. These guidelines have focused on intervals while rates have remained inconceivable low. A focus on raising screening rates is long overdue.

**An Immigrant Diabetes Disadvantage? Diabetes among US Versus Foreign Born Immigrants in East Harlem, New York**

Ashley M. Fox, Mount Sinai School of Medicine; Ashley Fox, Mount Sinai School of Medicine; Euny Lee, Mount Sinai School of Medicine; Kezhen Fei, Mount Sinai School of Medicine; Janice Scobie, Mount Sinai School of Medicine; Carol R. Horowitz, Mount Sinai School of Medicine

**Presenter:** Ashley Fox, Ph.D., M.A., Assistant Professor, Health Evidence and Policy, Mount Sinai School of Medicine, ashley.fox@mountsinai.org

**Research Objective:** Results across a variety of health conditions generally show an immigrant health advantage. One potential exception to this immigrant health advantage is diabetes, which is high among both U.S. born Hispanics and Hispanics born in Latin America. The lack of a diabetes advantage may be because obesity rates are rapidly increasing in Latin American countries, especially Mexico or because diabetes may only be detected once people arrive in the US. Most studies rely on self-reported measures of diabetes, which may be biased. This study draws on a unique cohort of overweight residents of East Harlem, New York, an epicenter of the Hispanic diabetes epidemic in the U.S., which collected biomarker information on respondents’ fasting blood glucose over a period of 2 years to assess whether foreign born residents had higher or
lower rates of diabetes and potential explanatory mechanisms.

**Study Design:** Oral glucose tolerance test (OGTT) were administered to assess prevalence of diabetes and pre-diabetes and biological data on height and weight were collected to measure BMI. Respondents were asked about whether they were born in the US, how long they had been in the US, their race, ethnicity and nationality, and a series of questions about health related behaviors. Respondents were followed up at 6, 12 and 24 months. This study reports on data from their baseline and 6 month follow up assessments and compares rates of diabetes between foreign born and US born respondents controlling for race, gender, bmi, employment, education, income and insurance status. The study compares both foreign born to US born generally and between specific groups (i.e., Puerto Ricans born on the US mainland to Puerto Ricans born on the Island).

**Population Studied:** 646 overweight (BMI 25+) English and Spanish speaking adult (18+) residents of East Harlem.

**Principal Findings:** Sixty-three percent of the sample was foreign born, 22% were black, 74% were Hispanic. Thirty-three percent identified as Mexican, 22% were Puerto Rican, 11% were Dominican and the rest identified as Other. Unadjusted and adjusted logistic regression results showed that foreign born had were two times more likely be diabetic compared with individuals born in the U.S. Surprisingly, most of this immigrant health disadvantage was explained by being born in Puerto Rico whereas being born in Mexico and the Dominican Republic was protective. When compared with Puerto Ricans born in the U.S., Puerto Ricans born on the island had 5 times higher odds of being diabetic (p<0.05). Foreign born were no more likely than US born individuals to progress to diabetes over the study period. Few differences between Puerto Ricans born on the U.S. mainland and in Puerto Rico were found that could explain their higher diabetes risk and Puerto Ricans born in the U.S. had a significantly higher BMI than Puerto Ricans born on the island.

**Conclusions:** A immigrant health disadvantage exists for diabetes among Puerto Rican immigrants born on the island compared with U.S. born, but a diabetes advantage exists for other groups.

**Implications for Policy, Delivery, or Practice:** More research needs to explore the mechanisms, including the island food environment that may create a higher risk for diabetes among Puerto Rican immigrants.

**Is the Quality of Surgical and Pneumonia Care Lower in Minority Serving Hospitals?**

Darrell Gaskin, Johns Hopkins Bloomberg School of Public Health; Hossein Zare, Johns Hopkins Bloomberg School of Public Health

**Presenter:** Darrell Gaskin, Ph.D., Associate Professor Of Health Economics, Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, dgaskin@jhsph.edu

**Research Objective:** Prior studies have found that racial and ethnic disparities in hospital quality are due to differences across hospitals rather than differences within hospitals. This calls into question the quality of care provided by hospitals serving minority patients. These studies imply that minority serving hospitals generally perform lower on quality indicators possibly due to a lack of resources, inadequate budgets, the inability to attract and retain clinical expertise, and a culture of high quality, and inadequate risk adjustment that fails to account for unobservable risk factors associated with their patient populations. This study used Medicare Compare data to explore the relationship between quality of care for surgical and pneumonia patients and the racial/ethnic composition of the hospitals’ patients.

**Study Design:** This is a observational study of a cross section of US hospitals from selected states. We estimated the association between the race/ethnic composition of patient population and quality using linear and conditional quantile regression models controlling for bed size, ownership, teaching status, percentage of discharge for Medicare and Medicaid patients, urban-rural location, median household income, specialty services index, Electronic Medical Record indicators, case mix index, FTE per adjusted admission, market share index (Herfindahl Index), hospital efficiency index and state fixed effects.

**Population Studied:** In this study we focused on acute care general hospitals from 11 states: AZ, CA, FL, IA, MA, MD, NC, NJ, NY, WA and WI. We selected these states because we could use their state inpatient discharge data to measure the racial and ethnic composition of their hospitals’ patients. We combined this information with 2012 data from Medicare
Hospital Compare. Specifically, we look at 18 indicators of timely and effective care measures: 12 surgical care indicators and 6 quality process indicators for pneumonia. We estimated the association between percentage of hospital quality indicators (for each indicator) and percentage of hospital discharges for Black, Hispanic, Asian and all other minority patients. We defined minority serving hospitals as those whose minority census was 65% or more, integrated hospitals as those with minority census between 35%-65% and majority white hospitals as those with fewer than 35% minority patients.

**Principal Findings:** We found that compared to majority white hospitals, minority serving and integrated hospitals were more likely to be larger, publicly-owned, investor-owned, teaching facilities, and located in urban areas. They offer more specialized services, served more Medicaid patients, fewer Medicare patients and had fewer decision support systems and with less efficiency index. The linear regressions showed minority serving hospitals scored lower on 6 of the 12 surgical indicators and 4 of the 6 pneumonia indicators. However, the quintile regressions should that the differences were really between the lowest performing minority serving/integrated hospitals and majority white hospitals. As we moved from 10th to 90th percentile the quality differences between hospitals by racial composition disappears.

**Conclusions:** In conclusion, the best minority serving/integrated hospitals perform as well as the best majority white hospitals. However, below average minority serving/integrated hospitals were worst than below average majority white hospitals.

**Implications for Policy, Delivery, or Practice:** Efforts to improve care for patients in minority serving/integrated hospitals should focus on the lowest performers. Special attention should be paid to these hospitals because they are significantly worse than other below average hospitals.

**Compliance with CLAS National Standards (Culturally and Linguistically Appropriate Services) in a Southern State: Kentucky’s Local Health Departments**

Maria Gomez, University of Kentucky College of Nursing; Torrie Harris, DrPH, Kentucky Office of Health Equity; Richard Charnigo, PhD, University of Kentucky College of Public Health

**Presenter:** Maria Gomez, Dr.P.H., M.P.H., Program Manager Public Health, Minority Health Research, University of Kentucky College of Nursing, maria.gomez@uky.edu

**Research Objective:** Main objectives were to: (1) Measure the extent to which local health departments (LHDs) in Kentucky comply with the National Standards for Culturally and Linguistically Appropriate Services (CLAS Standards, USDHHS); (2) Provide health policy recommendations for program development by LHDs based on the research findings.

**Study Design:** This is a cross-sectional survey administered to LHDs’ administrators from 56 counties in Kentucky. Instrument: Self-Assessment Tool for CLAS Standards in Local Public Health Agencies (USDHHS). Eight (8) CLAS assessment domains were utilized as measurements. Data Analysis: Scores were determined by CLAS domain. Statistical techniques included: descriptive statistics, 2 sample T-test, linear and logistic regression.

**Population Studied:** Public health directors, nurses, and program managers serving local health departments in Kentucky.

**Principal Findings:** A total of 159 Kentucky LHDs’ administrators received the survey, and 123 (77%) were returned. Responses were obtained from 40 rural counties and 16 urban counties. Findings suggest that rural and urban LHDs comply at moderate levels on the following domains: Plans and Policies; Quality Monitoring and Improving; Management Information Systems for Clients; and Staff Training and Development. Rural and urban LHDs comply at minimum levels on CLAS domains: Organizational Governance; Culturally Inclusive Health Care Environment for Educational Materials; and Staff Recruitment. Staff Training on cultural competency alone reflects a range from moderate to strong level of compliance with CLAS in both groups. The role of the public health nurse was more frequently associated with the implementation of CLAS practices in general.

**Conclusions:** Local health departments in Kentucky have implemented policies that comply with CLAS National Standards to moderate and minimum levels. Areas that need more development include: Organizational Governance; Culturally Inclusive Health Care Environment for Educational Materials; and Policies to Recruit Diverse Personnel.
This is the first study to present findings of levels of compliance with CLAS National Standards in a quantitative manner within an entire local public health system. This study may set the grounds for other states to follow, specifically states situated in the Southern area and Appalachian region in the United States.

Implications for Policy, Delivery, or Practice:
A cultural and linguistic competency organizational assessment is an overarching strategy for health organizations to achieve higher levels of quality of care which in turn will improve the quality of life, improve health outcomes, and eliminate health disparities. In addition, the practices of CLAS Standards may allow state and local health departments to adhere to the National Public Health Accreditation Board (PHAB) Standards for ensuring a culturally and linguistically competent public health system.

The Health Transportation Shortage Index and Geomapping to Assess Risk of Transportation Barriers to Health Care Access
Roy Grant, Children's Health Fund; Grifin Goldsmith MPH, Children's Health Fund; Stephen Borders PhD, Grand Valley State University, Allendale Michigan; Delaney Gracy MD, MPH, Children's Health Fund; Tracy Rostholder MPH, Children's Health Fund; Dennis Johnson MPA, Children's Health Fund

Presenter: Roy Grant, M.A., Senior Director Of Research, Medical Affairs, Children's Health Fund, rgrant@chfund.org

Research Objective: Geospatial access and availability of transportation are important factors in a child’s access to timely health care services. Nationwide, 4% of children (9% with household income <$50,000) missed at least one health care appointment each year because transportation was not available. One-third later used a hospital emergency department. Rural areas have less available public transit and higher poverty rates than metropolitan areas, making personal vehicle ownership essential and potentially unaffordable. Using multiple data sets including original survey data, census demographics and hospital discharge data, we developed and validated a tool, the Health Transportation Shortage Index (HTSI), designed to help health planners identify areas where transportation is a significant access barrier to child health services. In this study we applied the HTSI to each county in two diverse states, Mississippi and Michigan, to test its utility in identifying and ranking counties in which transportation may be an access barrier.

Study Design: We computed a HTSI score for each county in Mississippi and Michigan to quantify risk and mapped each county using ArcGIS, locating every federally qualified health center and rural health clinic (“clinic”) within the county. Euclidian distances to nearest clinic (including those in contiguous counties) were computed using geographic- and population-weighted centroids as starting points. Data were analyzed in SAS (version 10.0).

Population Studied: County populations in two diverse states.

Principal Findings: A HTSI cut score (8) was determined that correctly identified 75.2% of counties with 1 or 0 pediatricians and correspondingly few family practitioners (p<0.01); 87.0% of these counties had populations <30,000 (p<0.01); 78.8% had the highest poverty rates in their state (p<0.01); 76.4% had no fixed route transit system including 17.6% with no public transit resources at all (p<0.01). The mean HTSI score of these counties was 8.4; for the 24.7% of counties with 1 or 0 clinics the mean score was 9.2. These results correlated with HPSA (health professional shortage area) designation (p<0.01); 83.5% were full and 14.1% partial county HPSAs. The results suggest the HTSI score supplements HPSA designation to facilitate more sensitive risk ranking. Population-weighted analysis seems to best reflect travel distances for the majority of county populations. Geomapping revealed that clinic resources are well located relative to population centers, with mean travel distances generally <7 miles for the county. The longest travel distances were in the least populous (most rural) counties (p<0.01). For rural residential areas distant from population centers, travel distances to nearest clinic often ranged from 20 to 34 miles. HTSI scores reflect county populations, not population distributions. Supplementing HTSI scores with geomapping allows for further recognition of high-risk counties based on population distribution.

Conclusions: The Health Transportation Shortage Index is useful in assessing the relative need for additional resources to facilitate child health access and can help planners
prioritize among medically underserved counties.

Implications for Policy, Delivery, or Practice: Some families, especially in rural areas, have long travel distances and limited resources. Transportation availability should be assessed when scheduling appointments so assistance to facilitate adherence can be offered if needed.

Barriers to Psychosocial Services among Women Veterans Who Were Homeless
Alison Hamilton, VA Greater Los Angeles; Ines Poza, PhD, Poza Consulting; Vivian Hines, MSW, VA Greater Los Angeles; Donna L. Washington, MD, MPH, VA Greater Los Angeles & UCLA

Presenter: Alison Hamilton, Ph.D., M.P.H., Research Health Scientist, Desert Pacific MIRECC, VA Greater Los Angeles, alison.hamilton@va.gov

Research Objective: To provide a grounded description of barriers to psychosocial services among women veterans who were homeless.

Study Design: Focus group interviews subsequent to surveys.

Population Studied: 29 women veterans who had spent at least one night of the prior 30 in a shelter or transitional residential facility, a hotel paid for with a voucher, a car, an abandoned building, a nonresidential building, or another non-dwelling, or on the street.

Principal Findings: Participants described three main barriers to social and psychosocial services: (1) lack of information about services available to them, (2) limited access to services, and (3) lack of coordination across services. A sense of isolation and abandonment permeated women’s descriptions of their experiences of seeking and receiving services that were inappropriate or uncomfortable. Substance abuse was often a factor contributing not only to prolonged homelessness but also to utilization of services: many women found that they could only access services if they had—or claimed they had—substance abuse problems. Several participants who received appropriate and effective services were eager to share their experiences and concrete information about which services were worth utilizing. Participants enthusiastically endorsed the idea of women helping one another through the challenges of homelessness.

Conclusions: Homeless women deserve consideration as a distinct group within the homeless population, a group that perhaps exhibits unique ways of becoming homeless, responses to being homeless, and needs to prevent cycling in and out of homelessness. Furthermore, women veterans should be considered as a distinct subgroup of homeless women, especially considering their pathways into homelessness, including experiences specific to their military service. Our findings suggest the need for: (1) safe and stable housing for women veterans; (2) greater geographic availability of women-only treatment programs; (3) tailoring of mixed-gender programs to address safety concerns of women veterans and to improve coordination of care; (4) greater attention to the needs of women veterans without substance abuse and/or other mental health problems, and women veterans without children; and (5) interventions that incorporate a peer support and strengths-based or empowerment-oriented approach.

Implications for Policy, Delivery, or Practice: Understanding women veterans’ service needs and experiences related to homelessness, and the phenomenological underpinnings of those experiences, is critical to the development of relevant and appropriate services that move women away from vulnerability, into safety. Findings from this study improve our understanding of these issues, and inform actions to begin to address these needs. Future research should be directed toward identifying best practices for implementing these actions in VA clinical settings as well as settings outside the VA where homeless women veterans may seek care.

Impact of Massachusetts Health Reform on Hospitalizations, Length of Stay and Costs of Inpatient Care: Does Safety-Net Status Matter?
Amresh Hanchate, VA Boston Healthcare System/Boston Medical Center/Boston University School of Med.; Danny McCormick, Cambridge Health Alliance/Harvard Medical School; Chen Feng, Boston Medical Center/Boston University School of Medicine; Karen Lasser, Boston Medical Center/Boston University School of Medicine; Nancy R. Kressin, VA Boston Healthcare System/Boston
Medical Center/Boston University School of Med.

**Research Objective:** There is widespread concern that large-scale insurance expansion—such as that anticipated from the Affordable Care Act—has the potential to cause sharp increases in health care utilization and costs. In the setting of Massachusetts' landmark 2006 health care reform, we estimated pre-reform to post-reform changes in inpatient care volumes and costs, contrasting the experience of safety-net hospitals (SNH) as the predominant providers of care for targeted reform beneficiaries, with that of non-SNH.

**Study Design:** We analyzed MA Hospital Inpatient Discharge Data on all non-federal MA hospital discharges from 2004-2010 for 2,636,326 non-elderly patients (age 18-64) across all 66 short-term acute care hospitals. Safety-net hospitals were identified as those in the top quartile of hospitals (N=16) in the proportion of hospital admissions with Medicaid, Free Care (state-funded program for uninsured) and self-pay as the primary payer. Using the quarter as the unit of time, we examined longitudinal hospital-level changes in (a) number of admissions, (b) average length of stay (LOS; days), (c) average charge per day ($) and (d) average charge per stay ($), separately for SNH and non-SNH. We also examined changes for acute and non-acute admissions, and for subpopulations by race/ethnicity and socioeconomic status (SES; defined using patient zip code median income). We used linear regression models to estimate the average change between pre-reform (1/2004 to 6/2006) and post-reform (1/2008 to 6/2010) periods, adjusting for longitudinal changes in patient demographics and comorbidities. To better isolate the impact of reform from secular state-wide trends, we treated the elderly as the “control” population and used a difference-in-differences model specification.

**Population Studied:** MA-residing patients aged ≥18 and discharged from all non-federal MA hospital (2004-10).

**Principal Findings:** There was no significant post-reform change in the number of admissions; quarterly number of admissions per hospital were 1,480 pre-reform and 1,520 post-reform (p=0.68). A similar pattern was found for admissions at hospitals by safety-net status, for acute and non-acute admissions, and for minority and low-income subpopulations.

Average LOS increased by a smaller amount among SNH (0.20 days; 95% CI=[0.15, 0.25]) than among non-SNH (0.30 days; 95% CI=[0.27, 0.33]). Average charges per day decreased among SNH ($198; 95%CI=[$251, $145]) and increased among non-SNH ($249; 95%CI=[$215, $284]). A similar trend with a larger difference was found for average charges per stay (SNH=$477; 95%CI=[$768, $187]) and non-SNH=$1,442; 95%CI=[$1,248, $1,635]). Similar trends were found for both acute and non-acute admissions. Among blacks and Hispanics, none of the measures indicated larger increase in SNH compared to that in non-SNH; for low-income patients, increases in LOS and charges were smaller in SNH.

**Conclusions:** Following MA health reform, utilization of inpatient care did not increase at SNH, the predominant providers of inpatient care for populations targeted by the reform, compared to non-SNH. A similar trend was found for acute and non-acute admissions, and for minority and low-income subpopulations. Future analyses in the coming months will test robustness of these findings using the non-elderly patients from comparison states as the control population.

**Implications for Policy, Delivery, or Practice:** Insurance coverage expansion in MA may not have increased overall use of inpatient use and costs.

**Funding Source(s):** NIH

**Understanding Perceived Barriers to Fruit and Vegetable Consumption among Low-Income Individuals: A Qualitative Study**

Lindsey Haynes-Maslow, University of North Carolina Gillings School of Global Public Health; Sarah E. Parsons, MEM, Department of Environmental Management, Duke University; Stephanie B. Wheeler, PhD, MPH, University of North Carolina Gillings School of Global Public Health; Lucia A. Leone, PhD, University of North Carolina Gillings School of Global Public Health

**Presenter:** Lindsey Haynes-Maslow, M.H.A., B.S.P.H., Doctoral Student, Health Police and Management, University of North Carolina Gillings School of Global Public Health, lhaynes5@email.unc.edu
Research Objective: Obesity is the leading preventable cause of illness and a major contributor to chronic disease. Consuming fresh fruits and vegetables can help manage and prevent weight gain and reduce the risk of chronic diseases. Low-income individuals often lack access to stores that sell fresh fruit and vegetables and live closer to stores that sell low nutritional value foods. The purpose of this study is to understand perceived community-level barriers to fruit and vegetable consumption among low-income individuals.

Study Design: We used a qualitative approach to examine barriers to fruit and vegetable consumption. We conducted eight focus groups involving 68 low-income participants in two North Carolina counties from May 2011-August 2011. The socio-ecological model of health guided data analysis and two trained researchers coded the transcripts and used memo writing.

Population Studied: North Carolina is the 14th most overweight state in the nation (1). Orange and Durham County are a mix of urban and suburban communities. Approximately 25% of adults are obese, 16% are living in poverty; and 30% of residents of these counties lack access to healthy foods. Four focus groups were conducted in each county; one was all-male, five all-female, and two mixed-sex. Most participants were African American, female, and had a high school education or less.

Principal Findings: Five of the focus groups were predominately African American, two focus groups were elderly, and one was Latina. Almost half received either Supplemental Nutrition Assistance Program or another government assistance program. We identified six major community-level barriers affecting fruit and vegetable access: cost, transportation, quality, variety, changing food environment, and changing societal norms around food.

Conclusions: Participants identified six main barriers to eating fruit and vegetables: cost, transportation, lack of quality and variety, changing food environment, and changing societal norms. Cost was the most commonly and extensively described barrier to purchasing F&V. Across all focus groups, participants expressed a desire for increased quality and variety of fresh fruit and vegetables in the community. There also seemed to be an unmet demand for convenient locations to purchase high quality, fresh fruit and vegetables in low-income communities is an important finding.

Implications for Policy, Delivery, or Practice: Our study increases understanding of low-income individuals’ experiences in NC that may be relevant to other settings. Improving cost, quality, variety, and convenience of fresh fruit and vegetables are important issues in reducing chronic diseases. Policymakers should consider supporting programs that decrease cost and increase the supply of high quality fruit and vegetables in low-income communities. This may be done by encouraging grocery stores to locate into these communities, incentivizing convenience stores to carry more produce, or restricting the number of fast food restaurants that can locate into these communities. Additionally, policymakers should consider decreasing fruit and vegetable prices, either through subsidies or vouchers to address cost barriers. Lastly, policymakers should invest in culturally-appropriate nutrition programs that focus on increasing fruit and vegetable consumption among low-income individuals.

The PCMH Effect on Racial/Ethnic Minorities

Susan Hernandez, University of Washington;
Paul L. Hebert, PhD, Department of Veterans Affairs; Edwin S. Wong, PHD, Department of Veterans Affairs; Chuan-Fen Liu, PhD, Department of Veterans Affairs; Adam J. Battan, Department of Veterans Affairs; Jaclyn Lemon, Department of Veterans Affairs

Presenter: Susan Hernandez, MPA, Research Assistant, Health Services, University of Washington, seh315@uw.edu

Research Objective: In 2010 the Veteran Health Administration (VHA) began implementing a patient-centered medical home model system wide, the Patient Aligned Care Teams (PACT), to transform primary care into team-based care. Similar to other settings, within the VHA healthcare for minorities is concentrated among few providers, with 28% of all VHA hospitals caring for 75% of Black veterans. Disparities are also prevalent within the VHA system and across VHA facilities. This study tests whether the national PACT differentially affects facility level rates of hospitalizations for ambulatory care sensitive conditions (ACSCs) depending on the percent minority.
Study Design: We use an interrupted time series design, a mixed effects model, and the US Agency for Healthcare Research and Quality (AHRQ) definition of hospitalizations for ambulatory care sensitive conditions, which consist primarily of hospitalizations for heart failure, pneumonia, COPD, and diabetes. We adjust for clinic characteristics, and patient population characteristics, and the market level unemployment rate. Changes in hospitalizations for ACSC trends were assessed by incorporating separate intercepts and time trend slopes for the pre- and post-PACT periods. Wald tests were used to assess statistically significant differences between the pre- and post-PACT parameters. Using the estimated models, we compared the estimated post-PACT utilization trend with the projected hospitalization for ACSCs trend in the absence of PACT. We limit the analyses to veterans under 65 because nearly half of all healthcare utilization by Medicare-eligible Veterans occurs outside the VA, and these data are available to us only with a significant time lag. Clinics were categorized as low (<5%), medium (5%-15%), and high (>15%) based on the percent of black patients comprising their patient population.

Population Studied: The study sample included veterans who were under 65 and were assigned to a primary care provider from 2003 through 2012. The total number of facilities was 972, although 65 did not have unemployment rate data and were excluded from the main analyses. All patients were included regardless of whether they survived or remained a primary care patient through the PACT initiation period. Thus, patients who appeared only in the pre-PACT period contributed observations to estimate the trend in utilization pre-PACT. We aggregate individual level observations to facility level, so the unit of analysis was the facility-quarter.

Principal Findings: Overall, blacks represented less than 5% of patients in 49% of facilities; 5-15% in 28% of facilities, and more than 15% in 23% of facilities. Preliminary results based on collapsed pre- and post-PACT time periods indicate ACSCs rates increase with increase percent of blacks in a facilities.

Conclusions: Datasets are ready for the next steps including incorporating other racial/ethnic groups and incorporating other utilization categories. In addition, we will conduct the full time-series and veteran level analyses to calculate facility level ACSC rates for racial/ethnic groups.

Implications for Policy, Delivery, or Practice:
The VHA presents a unique opportunity to test whether the PCMH differentially affects rates of hospitalizations for ACSC within an integrated delivery system among varying levels of racial diversity in medical facilities. This study contributes to the growing evidence regarding the effectiveness of the PCMH and is the first to look at its effect on racial/ethnic groups.

Poster Session and Number: A, #231

Disparities in Evaluation of Regional Lymph Nodes among Black and White Women with Non-Disseminated Breast Cancer and Subsequent Outcome
Marianne Hillemeier, Penn State University; Weihong Kong, Penn State University

Presenter: Marianne Hillemeier, Ph.D., Penn State University, mmh18@psu.edu

Research Objective: One in three cancers diagnosed among women is breast cancer. Despite the fact that research has advanced breast cancer diagnosis and treatment dramatically over the past decades, black-white gaps in breast cancer-related mortality persist. In this paper, we examine whether race is significantly associated with the likelihood of lymph node evaluation among black and white women with non-disseminated breast cancer, and whether lymph node evaluation is independently associated with risk of dying within the follow-up period, controlling for race. We also assess whether the odds of having lymph node examination have improved since 2004, overall and by race.

Study Design: Data were drawn from 2012 Surveillance, Epidemiology, and End Results Data –linked to county attributes. Multivariate logistic regression models predicting lymph node evaluation among women with non-disseminated breast cancer were estimated controlling for explanatory variables including individual factors (race, age, stage at diagnosis, tumor grade, and marital status), treatment factors (surgery, radiation), and county-level factors (metropolitan county or not, median household income, percentage of the population with at least a college degree, and percentage of the female population aged 40+ receiving mammography within the previous two years). We also conducted Kaplan-Meier survival analyses and Cox proportional hazard
disparities in care have changed overtime. We examined whether quality of care differs for black, Latino, and white Medicaid beneficiaries with schizophrenia, and whether quality and disparities in care have changed overtime. We focused on Medicaid because Medicaid is the largest payer for this population.

Study Design: We used 2002-2008 inpatient, outpatient, and pharmacy data from the Medicaid Analytic Xtract database for a large and diverse state program. We created cohorts of continuously enrolled adults aged 18-64 years with at least two outpatient or one inpatient claim with a schizophrenia diagnosis. Subjects’ service use information was assembled into treatment episodes. We used 15 quality measures adapted from the schizophrenia PORT and generic chronic care standards to characterize quality of care. The measures covered pharmacological and psychosocial practices as well as indicators of appropriateness of care. We created a composite quality score for each treatment episode using the individual measures via item response theory [IRT] modeling. Using this composite score as our primary outcome, we estimated random regression models to quantify the association of race/ethnicity and time on quality, accounting for between-county variation.

Population Studied: 119,178 schizophrenia treatment episodes (29% black, 17% Latino, 54% white) for 48,225 beneficiaries across 58 counties.

Principal Findings: Although 83% of episodes had filled at least 1 antipsychotic prescription and 67% were fully adherent, rates of routine psychiatric care and timely follow-up following discharge were modest (both at 55%). Measures most discriminating of quality in the IRT model were routine psychotherapy, routine psychiatric care, and timely follow-up. The mean composite quality score for the state was 0.06 [SD = 1.26], ranging from -2.19 (low quality) to 2.38 (high quality).
quality) across the episodes. Statewide, in 2002 and compared to whites, blacks had lower quality (0.16 units lower [SE = 0.026]) and so did Latinos (0.07 units lower [SE = 0.027]). Annual rates of quality improvement were 0.057 [SE = 0.012] per year for whites, but improvement grew slower, by 0.015 annual units, for both blacks and Latinos.

Conclusions: Using a composite measure of quality of schizophrenia care encompassing a broad spectrum of treatment practices, we found evidence of disparities in quality, larger for blacks than Latinos, among Medicaid beneficiaries residing in a state where counties finance and administer health and mental health services. Although quality of care improved over the study period, it improved more for whites and hence, disparities grew.

Implications for Policy, Delivery, or Practice: Our findings have important implications for efforts to improve quality while also reducing disparities among vulnerable populations. Quality improvement efforts need to be designed to target all racial/ethnic groups equally, thus effecting progress in both quality and equity of care. Further research is needed to understand county-level policy and other contextual factors that may be associated with gains in both dimensions.

An Intervention to Extend Breastfeeding among Black and Latina Postpartum Mothers
Elizabeth Howell, Mount Sinai School of Medicine; Susan Bodnar-Deren, Department of Sociology, L. Douglas Wilder School of Government and Public Affairs, Virginia Commonwealth University; Amy Balbierz, Mount Sinai School of Medicine; Nina Bickell, Mount Sinai School of Medicine

Presenter: Elizabeth Howell, M.D., M.P.P., Associate Professor, Department of Health Evidence & Policy and Obstetrics, Gynecology, and Reproductive Science, Mount Sinai School of Medicine, elizabeth.howell@mountsinai.org

Research Objective: To evaluate the effectiveness of a randomized controlled trial with the secondary aim to test whether a behavioral educational intervention increased breastfeeding duration among low-income, self-identified black and Latina postpartum mothers.

Study Design: Randomized controlled trial at a large inner-city urban hospital. Participants were randomized to intervention or enhanced usual care groups. Participants randomized to the intervention arm received a culturally-tailored 2-step intervention that prepares and educates mothers about postpartum symptoms and experiences (including tips on breastfeeding and breast/nipple pain), bolstered social support and self-management skills, and included an in-hospital educational session with a social worker, educational materials, and a 2-week follow-up call. Mothers in both trial arms were interviewed prior to randomization (during their postpartum hospital stay), 3-weeks, 3-months, and 6-months postpartum and asked a series of questions about breastfeeding, (including how long they breastfed), physical and emotional symptoms, social support, and healthcare factors. Data were collected by bilingual research coordinators blinded to intervention status. Enhanced usual care participants received a list of community resources and a 2-week control call. We conducted intention-to-treat analyses examining breastfeeding duration (measured in weeks) at 3-weeks and 3-months postpartum. Intervention status was the key independent variable in our analysis. Bivariate analysis was conducted to assess any demographic, clinical and breastfeeding characteristics of study participants. Among women who initiated breastfeeding, Kaplan Meier analysis was used to test the effect of the intervention on breastfeeding duration for up to 3-months of follow-up.

Population Studied: 540 self-identified black and Latina postpartum women were recruited during their postpartum hospital stay. Eligible subjects were women >18 years of age, English or Spanish Speaking, had working telephones, and had infants whose birthweights were > 2500 grams and 5-minute Apgar scores >6.

Principal Findings: Mean age was 28 (range 18-46); 62% were Latina and 38% were black. Sixty-three percent had Medicaid insurance, 56% earned < $30,000 annually, 35% were foreign born, and 21% spoke Spanish. Among the 540 mothers enrolled, rates for follow-up interviews were 87% at 3-weeks, and 89% at 3. Of the 540 participants, 425 women (79%) initiated breastfeeding. There were no important differences between intervention and control groups in baseline sociodemographic, clinical, psycho-social, and breastfeeding characteristics including rates of initiating breastfeeding. Among 425 women who initiated breastfeeding, women in the intervention group versus controls breastfed for longer (mean of 14.6 vs. 12.5
weeks p=.02) and were more likely to breastfeed at 3-weeks (84% vs. 75%, p=.04) and at 3-months postpartum (60% vs. 48%, p<.02). Kaplan Meier analysis revealed a statistically significant difference in time to cessation between the intervention and control group (log rank test, p=0.02).

Conclusions: A behavioral educational intervention increased breastfeeding duration among low-income, self-identified black and Latina women during the three-month postpartum period.

Implications for Policy, Delivery, or Practice: A simple, inexpensive culturally tailored intervention increased duration of breastfeeding among low-income, black and Latina mothers. More research is needed to determine whether this intervention is effective in other settings.

Guideline-Concordant Cancer Care among American Indian/Alaskan Native Patients with Cancer

Sara Javid, University of Washington; Thomas Varghese, MD, MS, University of Washington Department of Surgery; Arden Morris, MD, University of Michigan Department of Surgery; Michael Porter, MD, MS, University of Washington Department of Surgery; Dedra Buchwald, MD, University of Washington Division of General Internal Medicine; David Flum, MD, MPH, University of Washington Department of Surgery

Presenter: Sara Javid, M.D., Assistant Professor Of Surgery, Surgery, University of Washington, sjavid@uw.edu

Research Objective: American Indians/Alaskan Natives (AI/ANs) have the worst 5-year cancer survival among all racial/ethnic groups in the United States. Improved cancer survival is linked to the receipt of guideline-concordant care. We sought to compare the receipt of guideline-concordant cancer care among AI/AN patients to White patients.

Study Design: Nationally accepted guidelines for surgical therapy, adjuvant (chemoradiation) therapy, and post-therapy surveillance were selected as metrics of optimal, or guideline-concordant, care. The proportion of patients receiving optimal care was compared across subgroups. Analyses comparing AI/AN patients to Whites utilized random sampling and bootstrapping methods along with matching for defined covariates. To analyze the association between receipt of each optimal care metric and survival among AI/AN and Whites, we performed Cox proportional hazards regression analyses.

Population Studied: Using Surveillance, Epidemiology, and End Results (SEER) registry data linked to Medicare claims, we identified 338,204 patients diagnosed at age 65 or older with the four most common solid tumors (breast, colon, lung, prostate) between January 1, 1996 and December 31, 2005. In order to ensure complete claims data, we required continuous enrollment in both Medicare Parts A and B, with no health maintenance organization (HMO) coverage for the entire or partial study period as defined for each metric.

Principal Findings: Across cancer types and points of care, AI/AN patients received less optimal care than White patients. AI/AN patients were universally less likely to have a curative surgical resection (p less than 0.02 across all cancer types). Adjuvant therapy rates were significantly lower for AI/AN patients with breast (p less than .0001) and colon cancer (p=.004). Rates of post-treatment surveillance were also lower among AI/AN patients across cancer types, and statistically significant for breast (p=.002) and prostate (p less than .001) cancer. Non-receipt of optimal cancer treatment was associated with significantly worse survival across cancer types. Survival hazard ratios for those who did not undergo surgery versus those who did were significantly lower for breast (HR 0.58), colon (HR 0.68), prostate (HR 0.6), and lung (HR 0.34) cancer. Survival rates were also significantly lower for those patients who did not receive adjuvant therapy for breast (HR 0.52) or colon cancer (HR 0.56).

Conclusions: AI/AN patients received lower quality care than White patients across the four most common cancer types and across the continuum of cancer care, including surgery, receipt of adjuvant therapy, and surveillance.

Implications for Policy, Delivery, or Practice: Efforts to explain these differences, including the associated geopolitical, community, and individual factors, are critical to advancing the delivery of optimal cancer care for AI/AN patients. Ongoing CINCO collaborative efforts will focus on more micro level analyses in collaboration with AI/AN communities, including key informant interviews and patient-provider dyad surveys, to elucidate the barriers to receiving cancer treatment and inform appropriate targets for intervention.

**Differential Response Rates Explain Disparities in Hospital Performance on HCAHPS**

Karen Joynt, Harvard School of Public Health; Sidney T. Le, Harvard School of Public Health; E. John Orav, Harvard School of Public Health; Ashish K. Jha, Harvard School of Public Health

**Research Objective:** Patient experience is an important metric of the quality of care delivered by a hospital, and is increasingly being used to rate hospitals’ performance and to determine reimbursement. Prior studies have shown that hospitals that serve a high proportion of poor and minority patients perform worse on the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. However, some have raised concerns that response rate may impact these differences, since disadvantaged patients may be less likely to respond to surveys. Therefore, our objective was to determine if response rate differed between safety-net or minority-serving hospitals and their peers, and to determine if these differences impacted HCAHPS scores.

**Study Design:** We used national hospital-level HCAHPS survey data from 2010. We linked this data to the 2010 American Hospital Association (AHA) survey to obtain hospital characteristics including size, ownership, location, teaching status, region, and Disproportionate Share (DSH) Index, a measure of the proportion of care that is provided to the poor. We used national Medicare data from 2010 to calculate the proportion of Medicare patients at each hospital that were black. We first calculated the performance on each HCAHPS domain across quartiles of DSH Index and across quartiles of the proportion of black patients served. We then repeated these calculations adjusting for the hospital characteristics listed above, and finally adjusting for response rate.  

**Population Studied:** 3,651 acute care US hospitals that reported in the HCAHPS and AHA surveys in 2010.  

**Principal Findings:** Prior to adjusting for response rate, we found that hospitals in the highest quartile of DSH Index, commonly referred to as safety-net hospitals, scored significantly worse on overall measures of patient experience. For example, 63.3% of patients at safety-net hospitals rated the hospital as a 9 or 10, compared with 71.6% at hospitals in the lowest quartile of DSH Index (difference 8.3%, p<0.001). Similarly, hospitals in the highest quartile of the proportion of black patients served scored significantly worse on patient experience, with 65.2% of patients rating the hospital a 9 or 10 compared with 70.9% at hospitals with the lowest proportion of black patients (difference 5.7%, p<0.001). However, after adjusting for response rate, these findings changed. For safety-net hospitals versus low-DSH hospitals the difference shrank (66.5% versus 68.6%, difference 2.1%, p<0.001) and for minority-serving versus low-minority hospitals the difference vanished (67.6% versus 68.2%, difference 0.6%, p=0.17). These patterns were very similar for each of the 10 HCAHPS domains examined.

**Conclusions:** Accounting for differential response rates attenuates or eliminates differences in patient experience ratings between safety-net and non-safety-net or minority-serving versus non-minority-serving hospitals.

**Implications for Policy, Delivery, or Practice:** Response rates may explain a large amount of the perceived difference in performance between hospitals on metrics of patient experience, particularly for hospitals with vulnerable patient populations. Given that these metrics are being used for hospital reimbursement, the consequences of failing to account for response rate may include worsening disparities in care.

**Racial Disparity in Duration of Patients’ Visits to the Emergency Department: Teaching vs. Non-Teaching Hospitals**

Zeynal Karaca, Social and Scientific Systems, Incorporated; Herbert S. Wong, Agency for Healthcare Research and Quality

**Presenter:** Zeynal Karaca, Ph.D., Health Economist, Center for Delivery, Organization, and Markets, Social and Scientific Systems, Incorporated, zeynal.karaca@ahrq.hhs.gov

**Research Objective:** The sources of racial disparity in duration of patients’ visits to emergency departments (EDs) have not been
documented well enough for policymakers to distinguish patient-related factors from hospital- or area-related factors. This study explores the racial disparity in duration of routine visits to EDs at teaching and non-teaching hospitals.

**Study Design:** Retrospective data analyses and multivariate regression analyses were performed to investigate the racial disparity in duration of routine ED visits at teaching and non-teaching hospitals. Duration for each visit was computed by taking the difference between admission and discharge times.

**Population Studied:** The Healthcare Cost and Utilization Project (HCUP) State Emergency Department Databases (SEDD) were used in the analyses. The data include 4.3 million routine ED visits encountered in Arizona, Massachusetts, and Utah during 2008. In general, the SEDD provide detailed diagnoses, procedures, total charges, and patient demographics. Demographics include gender, age, race, and insurance coverage (i.e., Medicare, Medicaid, private insurance, other insurance, and uninsured). However, the SEDD from these three states also provide admission and discharge time for each visit, from which duration may be calculated. We obtained information about hospital characteristics (i.e., urban versus rural, ownership status, teaching status, bed size, and system membership) from the 2008 American Hospital Association Annual Survey Database. In addition, we obtained information about the trauma level of the hospital using the Trauma Information Exchange Program database, collected by the American Trauma Society and the Johns Hopkins Center for Injury Research and Policy. Finally, we used the 2008 Area Resource File to obtain county-level income information.

**Principal Findings:** The mean duration for a routine ED visit was 238 minutes at teaching hospitals and 175 minutes at non-teaching hospitals. There were significant variations in duration of routine ED visits across race groups at teaching and non-teaching hospitals. The risk-adjusted results show that the mean duration of routine ED visits for black/African American and Asian patients when compared to visits for white patients was shorter by 10.0 and 3.4 percent, respectively, at teaching hospitals; and longer by 3.6 and 13.8 percent, respectively, at non-teaching hospitals. Hispanic patients, on average, experienced 8.7 percent longer ED stays when compared to white patients at non-teaching hospitals.

**Conclusions:** There is significant racial disparity in the duration of routine ED visits, especially in non-teaching hospitals where non-white patients experience longer ED stays compared to white patients. The variation in duration of routine ED visits at teaching hospitals when compared to non-teaching hospitals was smaller across race groups.

**Implications for Policy, Delivery, or Practice:** Our findings inform public and private policymakers on a broad range of issues including, but not limited to, admission day of the week, hospital volume, and the impact of hospital bed size on the mean duration of ED visits.

**Funding Source(s):** No Funding

**Racial Disparity in Hospital Inpatient Cost: Homeless vs. Non-Homeless Patients**

Herbert S. Wong, Agency for Healthcare Research and Quality; Zeynal Karaca, Social and Scientific Systems, Incorporated

**Presenter:** Zeynal Karaca, Ph.D., Health Economist, Center for Delivery, Organization, and Markets, Social and Scientific Systems, Incorporated, zeynal.karaca@ahrq.hhs.gov

**Research Objective:** There is limited literature addressing the racial disparity in hospital inpatient services among homeless patients. However, there is no study empirically comparing the racial disparity in hospital inpatient cost between homeless and non-homeless patients. This paper compares hospital inpatient costs between homeless and non-homeless patients across race groups using novel methodological approaches involving propensity score matching techniques. This study also provides comprehensive descriptive information on patient characteristics, insurance coverage, disease prevalence, and severity of illness for homeless patients and non-homeless patients by race groups.

**Study Design:** We employed propensity score matching to create two cohorts, where inpatient hospital visits between homeless and non-homeless patients were matched based on patients’ demographics and clinical information, and hospital types. These new similar cohorts were then used to compare the cost per hospital visit between homeless and non-homeless patients through multivariate regression analysis. We further verified our matching algorithm by testing the mean values of
covariates on our individuals where inpatient hospital visits encountered by homeless patients were paired with inpatient hospital visits encountered by non-homeless patients. **Population Studied:** The Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID) for 2009 were used. Data were drawn from 579 hospitals reporting data on homelessness in Arizona, California, Colorado, Florida, Georgia, Massachusetts, Missouri, New York, Pennsylvania, and Wisconsin. SID provide detailed diagnoses, procedures, total charges and patient demographics including homelessness. We linked SID files with American Hospital Association Annual Survey Database and Area Resource File to obtain hospital and area level characteristics. **Principal Findings:** Our risk adjusted results show that homeless patients generally have lower inpatient costs when compared to non-homeless patients. We find that homeless white patients have higher inpatient costs and non-homeless white patients have lower inpatient costs when compared to their homeless non-white and non-homeless non-white counterparts respectively. We also find that the majority of homeless children at hospital inpatient departments are non-white. In addition, about a third of all inpatient hospital visits by white homeless patients are for female individuals. We further found that about 29 percent of hospitalized homeless patients were uninsured, and that rate was dramatically lower for their non-homeless counterparts. Nearly half of inpatient hospital visits by homeless patients and about a quarter of inpatient hospital visits by non-homeless patients were covered by Medicaid. We observed a disproportionally higher prevalence of mental disorders relative to other disease groups within homeless patient populations in inpatient hospitals. Finally, we found that about 21 percent of all inpatient hospital visits by homeless individuals were related to mental disorders—mostly alcohol-related disorders, mood disorders, and schizophrenia and other psychotic disorders. **Conclusions:** We find significant variations in inpatient costs between homeless and non-homeless patients across race groups. While the majority of our results confirm the findings of previous research, we make several important new observations regarding hospital admission rates through emergency departments and substantial differences in racial composition across several categories, including age, gender, insurance coverage, and prevalence of major disease groups. **Implications for Policy, Delivery, or Practice:** This study provides comprehensive empirical evidence for racial disparity in hospital inpatient costs between homeless and non-homeless patients. **Funding Source(s):** No Funding **Poster Session and Number:** A, #238 **Racial and Diagnostic Disparities in Hospice Use and Effects of Hospice on Use of Acute Care Services at the End-of-Life** Pauline Karikari-Martin, Rush University; Judith J. McCann, PhD, RN, Rush University, CON & Rush Institute for Healthy Aging; Carol J. Farran, DNSSc., RN, Rush University, CON; Liesi Hebert, ScD, Rush Institute for Healthy Aging; Samuel C. Haffer, PhD, Centers for Medicare & Medicaid Services; Marcia Phillips, PhD, RN, Rush University, CON **Presenter:** Pauline Karikari-Martin, Ph.D(c), M.P.H., M.S.N., Nurse Officer, College of Nursing(CON), Rush University, pauline_karikari-martin@rush.edu **Research Objective:** This study examined racial and diagnostic differences associated with hospice use and duration of hospice use among individuals aged 65 years or older at the end-of-life (EOL). Secondly we examined the effect of race, diagnosis, and hospice use on acute care services: hospitalizations, intensive care unit/coronary care unit (ICU/CCU) admissions, and emergency room (ER) visits. **Study Design:** The Hospice Use Model guided this secondary analysis. Existing interview data from the Chicago Health and Aging Project (CHAP), a NIH-funded longitudinal community study of more than 10,000 people age 65 or older, were merged with Medicare claims information. Data were analyzed using logistic and Poisson regression using forward stepwise selection. **Population Studied:** CHAP participants who died as of December 31, 2009 and were enrolled in Medicare for at least one year before death (n=2,954) were included in the analytic sample. **Principal Findings:** Compared to Whites (45%), Blacks (55%) were less likely to use hospice (OR = .54; CI .38, .77). Compared to individuals with a non cancer diagnosis (61%), individuals with a cancer diagnosis (39%) were more likely to use hospice (OR=2.22; CI 1.79,
2.70). There were no racial or diagnostic differences in duration of hospice use. In models that considered race and diagnosis, hospice users (34%) were less likely than non-users (66%) to be hospitalized (RR=.53; CI .40, .69), have an ICU/CCU admission (RR=.38; CI .20, .71), or an ER visit (RR=.15; CI .11, .22) at the EOL.

**Conclusions:** Disparity in hospice use exists by race (Blacks vs. Whites) and by diagnosis (cancer vs. non-cancer) at the EOL. The effect of hospice use on hospitalizations, ICU/CCU admissions, and ER visits is statistically and clinically significant. In multivariate models, hospice use had a more powerful effect on use of acute care services than any other variables and it eliminated racial and diagnostic disparities in ER visits at the EOL. Overall, hospice use is more influential on use of acute care services at the EOL than race, diagnosis, age, education, physical function activities of daily living, and change in cognitive function.

**Implications for Policy, Delivery, or Practice:** Appropriate use of hospice services at the EOL can reduce the use of aggressive interventions and conserve health care resources. Efforts to disseminate and increase awareness of benefits of hospice should employ innovative educational strategies targeting minorities (Blacks) and individuals with a non-cancer diagnosis using a three-pronged approach: 1) Community – faith-based organizations, community leaders, family/caregivers, patient advocates, Medicare beneficiaries, and lay patient navigators; 2) Providers – nurse practitioner/physician residency programs, annual continuing education training, certification/seminar in palliative care, and medical encounter checklist that includes hospice benefit information; and 3) Payors – include hospice benefit information for enrollees during enrollment and re-enrollment periods.

**Survivors Foregoing or Delaying Care: A Lasting Effect of Cancer-Related Financial Problems?**

Erin Kent, National Cancer Institute; Laura P. Forsythe, Patient-Centered Outcomes Research Institute; K. Robin Yabroff, National Cancer Institute; Kathryn E. Weaver, Wake Forest School of Medicine; Janet S. de Moor, National Cancer Institute; Juan L. Rodriguez, Centers for Disease Control and Prevention; Julia H. Rowland, National Cancer Institute

**Presenter:** Erin Kent, Epidemiologist, National Cancer Institute, erin.kent@nih.gov

**Research Objective:** Financial problems caused by cancer and its treatment can substantially affect survivors and their families and create barriers to seeking healthcare. Little research has examined the effects of self-reported financial problems among cancer survivors. Our research objective was to identify factors associated with cancer-related financial problems in survivors and examine whether having financial problems was associated with delaying or foregoing medical care over the past 12 months.

**Study Design:** We used data from the cancer control supplement of the 2010 National Health Interview Survey (NHIS), a nationally representative, population-based cross sectional survey, which included the following question and responses: “to what degree has cancer caused financial problems for you and your family – a lot, some, a little, or not at all.” Using multivariable logistic regression analyses, we report sociodemographic, clinical, and treatment-related factors associated with perceived cancer-related financial problems and the association between financial problems and foregoing or delaying healthcare because of cost. We report adjusted percentages using the predicted margins method and incorporated sampling weights in the analyses to account for the complex sampling design.

**Population Studied:** Individuals with a self-reported history of cancer (excluding non-melanoma skin cancer) in adulthood from the 2010 NHIS study were included in the analyses (n= 1,556).

**Principal Findings:** Cancer-related financial problems were reported by 31.8% (CI 29.3-34.5%) of survivors. Factors significantly associated with cancer-related financial problems in survivors included younger age at diagnosis, minority race/ethnicity, history of chemotherapy or radiation treatment, recurrence or multiple cancers, and shorter time from diagnosis. After adjustment for covariates, respondents who reported financial problems were more likely to report delaying (14.6% vs. 7.5%) or foregoing overall medical care (11.2% vs. 5.0%), prescription medications (14.3% vs. 7.4%), dental care (18.5% vs.9.1%), eyeglasses (11.7% vs. 6.1%), and mental health care (3.5% vs. 1.5%) than their counterparts without financial problems (all p<0.05).
Conclusions: Almost one third of individuals with a history of cancer report cancer-related financial problems. Cancer-related financial problems are not only disproportionately represented in survivors who are younger, minority, and have a higher treatment burden, but may also contribute to poor healthcare access after cancer, which may have important implications for the health status of many cancer survivors.

Implications for Policy, Delivery, or Practice: Future research should utilize longitudinal study designs, such as those found in the Medical Expenditure Panel Survey, to examine economic trajectories of cancer survivors and their caregivers and whether cancer survivors who delay or forego care because of cost experience worse health outcomes. Questions about financial burden could also be added to existing, longitudinal survivor cohort studies. Findings also suggest the need for system and environmental-level solutions to minimize financial barriers to healthcare access for the growing population of cancer survivors.

Funding Source(s): NIH

Concluding Remarks: The targeted population of this study was congregants and churches that comprised a voluntary church network established to engage churches in collaborative research and education. This analysis includes a total of 1,194 African American congregants from 11 participating churches.

Principal Findings: Using Generalized Estimating Equations (GEE) models with a logistic link function, results suggest that, according to the multivariate models, congregants who reported having two or more health conditions, participated in a research project in the past two years, and were trying to lose weight were more likely to actively help in their church’s health ministry.

Conclusions: These findings suggest that congregants may be potentially driven to promote healthy behavior because of their own health challenges. Further, in looking at our original hypothesis, the findings highlight the need for further research to explore levels of active participation in health promotion and the variability between different ethnicities with regard to motivating factors such as personal health and research participation.

Implications for Policy, Delivery, or Practice: Identification of specific characteristics can significantly inform and enhance the design of future interventions that more effectively target
agents of change with the objective of furthering health promotion in church communities.

**Funding Source(s):** NIH

**Poster Session and Number:** A, #241

**Cardiovascular Disease Among African American Men: Partnering with the Church to Promote Better Health and the Value of Participant Observations**

Mimi Kim, University of North Carolina at Chapel Hill; Keon Gilbert, University of St Louis; Geni Eng, University of North Carolina at Chapel Hill; Daniel Howard, The Robert Wood Johnson Foundation for Health Policy at Meharry Medical College; Giselle Corbie-Smith, University of North Carolina at Chapel Hill; Paul Godley, University of North Carolina at Chapel Hill

**Presenter:** Mimi Kim, PhD, Investigator, Cecil G. Sheps Center for Health Services Research, University of North Carolina at Chapel Hill, mimi@unc.edu

**Research Objective:** American men have the highest mortality rate from cardiovascular disease (CVD) in this nation. Researchers have found that behaviors associated with managing and controlling CVD, such as seeking treatment, controlling diet, and exercising, may be significantly influenced not only by a man’s awareness and knowledge, but also by his racial/ethnic identity, gender role socialization, and culture, among other influences. Further, religious involvement and social support have been positively associated with a range of health outcomes, including cardiovascular functioning. However, efforts to translate this research to church-based, social support interventions that benefit African-American men have been rare and largely unsuccessful. In order to better bridge effective, research-based interventions with positive change for African-American men, this study initially examined the African-American church contexts through participant observation.

**Study Design:** Participant observations were used as an effective method for data collection to familiarize the research team with the participating churches; to observe the culture within the various churches; to observe any potentially significant cultural tools; to begin to build rapport with the congregation and broader community; and to encourage the insight of the research team.

**Population Studied:** A total of 20 participant observations were conducted in a variety of contexts across 4 southern, rural African-American churches including: Sunday service, Bible study, fellowship hour, men’s meetings, NAACP Chapter Meeting, Sunday school, and intercessory prayer.

**Principal Findings:** These observations proved to be an effective strategy for accessing hard-to-reach African-American men within a religious setting. These findings identify specific themes related to ethnicity, culture, religion, and other personal and social characteristics that provide insight into the lives of these men who have historically dealt with CVD. Further, the findings also identify specific elements of our particularly rigorous participant observation process and subsequent analysis that may assist future researchers to conduct effective and ethical observations in other hard-to-reach populations and/or settings.

These results provide evidence about the spaces and places men gather to express themselves and how they build community among themselves separate and in tandem with the rest of the community.

**Conclusions:** The process of conducting participant observations provided a rich and valuable picture of the cultural context in these rural African American churches. The data also provides a good balance of the strengths and areas to improve on for reaching African American men’s awareness of the importance of cardiovascular disease and health in general. Finally, this study and the observations in particular provide a strong foundation for how future studies can build a partnership with churches to promote health behaviors from a peer based model.

**Implications for Policy, Delivery, or Practice:** Identifying cultural contexts is critical to community based participatory research and enriches the positive impact of health interventions delivered in faith-based contexts. Participant observations are one method that can invaluably inform intervention design and subsequent clinical practices for promoting positive cardiovascular health in African American churches.

**Funding Source(s):** NIH

**Poster Session and Number:** A, #242

**Examining Characteristics of Individuals Who have Previously Participated in Research to Address Disparities in Minority Study Recruitment**

Mimi Kim, University of North Carolina at Chapel Hill; Adebowale Odulana, University of North
Research Objective: There is a well-established understanding that African American churches can serve as a significant portal to promote healthy living. As a result, it is important to identify the characteristics of individuals who have participated in research in the past for the following several reasons: provides a measure of the congregations “readiness” for participation in community based participatory research; informs the tailoring of health interventions that speak to the needs and experiences of the members of that specific church community; inform pastors of various ways to partner with research entities to address relevant health behaviors and conditions for their congregation members; and allow community academic research partners to understand what has successfully engaged congregation members in the past that may potentially motivate them and their peers to engage in future research. This analysis measured the odds of congregation members having participated in research in the past when controlling for various basic demographics, health factors, beliefs on the role of the church in health, lifestyle & environmental issues, and other variables related to participation in church based research.

Study Design: This analysis tests the hypothesis that individuals who have previously participated in research are more likely to be individuals who have had a family member or loved one who has been diagnosed with a health condition but maintain good health and wellness for themselves. The outcome variable was based on the following item: “In the past two years, I have participated through my church in a research project that promotes health”. The independent variables included variables across the following domains of determinants: personal, health factors, beliefs about the role of the church, and lifestyle & environmental issues.

Population Studied: The target population in this study was congregants and churches that were predominately African American in North Carolina that comprised a voluntary church network established to engage churches in collaborative research and education. The analysis included a total of 1,194 African American congregants from 11 participating churches.

Principal Findings: Using Generalized Estimating Equations (GEE) models with a logistic link function. According to the multivariate model results, physical activity was significantly associated with increased odds of prior research participation, as did readiness to participate and willingness to use computer to find health information. Smoking and physical inactivity in neighborhood were associated with lower odds of prior research participation.

Conclusions: These findings suggest that congregants who are physically active and proactively seek relevant health information via web-based technology are more likely to have prior research participation. Further, the findings highlight the need for further research to explore motivating factors such as personal health, technological expertise and their association to research participation and the variability between different ethnicities with regard to these kinds of factors.

Implications for Policy, Delivery, or Practice: Identification of specific characteristics can significantly inform and enhance the design of future interventions that more effectively target individuals who have previously participated in research with the objective of furthering identifying ways to ensuring the continued participation of those individuals in addition to increased minority recruitment via strategies that are informed by findings such as ours.

Racial/Ethnic Differences in Medical Care Access among Adult Cancer Survivors
Christopher King, MedStar Heath; Jie Chen, PhD, University of Maryland

Presenter: Christopher King, M.H.S., Assistant Vice President, Health Services Administration, MedStar Heath, cking@umd.edu

Research Objective: To investigate differences in the likelihood of having health care access barriers among white, African American and Hispanic cancer survivors and to quantify factors that can explain the differences.

Study Design: Logistic regressions were applied to examine the likelihood of reporting
each barrier, while controlling for demographic and socioeconomic variables. The Fairlie decomposition technique was applied to explore contributing factors that contribute to disparities in accessing medical care and treatment.

**Population Studied:** Data were merged from the 2000-2011 National Health Interview Survey (NHIS) to identify 12,148 adult cancer survivors who reported one or more of the following barriers to care: 1) delay or forgo medical care or treatment because of cost; 2) delay medical care because of organizational barriers; and 3) delay medical care because of transportation.

**Principal Findings:** Compared to whites, African Americans were more likely to delay medical care due to organizational barriers in the adjusted model (OR: 1.72; 1.43-2.06). The predicted probability of delaying medical care or treatment because of cost was higher for Hispanic (.38) and African American (.35) survivors than whites (.29). The predicted probability of delaying care due to organizational barriers was .14 for whites, .18 for African Americans and .21 for Hispanics. For delaying care due to transportation barriers, the probability was .04 for whites, .09 for African Americans and .06 for Hispanics. Age, marital status, insurance, perceived health, source of care, and language were identified as leading covariates that contribute to access-to-care disparities among minority cancer survivors.

**Conclusions:** Affordability, organizational and transportation barriers negatively impact survivors’ ability to obtain timely medical care and treatment. While expanded coverage under the Patient ProtecToin and Affordable Care Act may increase the percentage of Americans with medical coverage, socio-cultural factors may still contribute to disparities in access.

**Implications for Policy, Delivery, or Practice:** Health services leaders and cancer care providers should integrate culturally and linguistically tailored best practices in their day to day operations. Incentives should be offered for organizations that adopt national standards, such as the Office of Minority Health’s Culturally and Linguistically Appropriate Standards.

**Health Care Access Barriers among Cancer Survivors by Race/Ethnicity**

Christopher King, MedStar Heath; Rada K. Dagher, PhD, University of Maryland

**Presenter:** Christopher King, M.H.S., Assistant Vice President, Health Services Administration, MedStar Heath, cking@umd.edu

**Research Objective:** To examine the prevalence of three common access-to-care barriers and determine whether cancer history and race/ethnicity are associated with the likelihood of reporting barriers.

**Study Design:** Data from the National Health Interview Survey (NHIS) from 2006-2010 were used to identify 2,281 adult cancer survivors (ages 18-64) and 243,925 adults without a history of cancer. Self-reported barriers for delaying medical care because of costs, organizational barriers and transportation were explored by race/ethnicity and cancer history using multivariate logistic regression.

**Population Studied:** Data from the National Health Interview Survey (NHIS) from 2006-2010 were used to identify 2,281 adult cancer survivors (ages 18-64) and 243,925 adults without a history of cancer.

**Principal Findings:** Overall, 31% of cancer survivors reported at least one of the three barriers to medical care, compared to 15% of the general population. Eighteen-percent of survivors reported cost barriers, 14% reported organizational barriers and 3% reported transportation barriers. Cancer survivors who were African American or Hispanic were more likely to report cost barriers, compared to Whites in logistic regression models. Survivors with a history of cancer were more likely to report organizational barriers compared to the general population.

**Conclusions:** As cancer survivorship increases in the United States, findings suggest that survivors are less likely to receive routine and timely medical care than the general population. Specialized interventions aimed to reduce or eliminate access to care barriers for cancer survivors should be tested and implemented. Moreover, disparities in reported barriers by race/ethnicity underscore the need for additional research to examine socio-cultural factors that impede access.

**Implications for Policy, Delivery, or Practice:** Incentives should be provided for organizations that adopt local or national standards around culturally and linguistically appropriate care. Due to the effectiveness of patient navigators, reimbursement or payment should be considered for providers that offer such services.

**Funding Source(s):** N/A

Healthcare Disparities in the Developing Context: Hospital Childbirths in Northern Thailand

Stephanie Koning, University of Wisconsin-Madison School of Medicine and Public Health; Elizabeth A. Jacobs, MD MAPP, University of Wisconsin School of Medicine and Public Health-Madison

Presenter: Stephanie Koning, B.S., Doctoral Student, Population Health Sciences, University of Wisconsin-Madison School of Medicine and Public Health, smgay@wisc.edu

Research Objective: Despite many health campaigns, childbirth remains a dangerous experience for women and infants in many developing countries. Childbirths are considered safest at a hospital; however, many women still give birth at home. Our study examines the socio-demographic characteristics that contribute to the likelihood of women giving birth at hospitals in northern Thailand.

Study Design: We used a hierarchical logistic regression to model the odds of women giving birth to their children in a hospital as related to certain socio-demographic characteristics—including ethnicity, education level and languages spoken at home—while controlling for age, wealth, village-level, and district-level effects.

Population Studied: Our study uses cross-sectional data from the United Nations Educational, Scientific and Cultural Organization Highland Peoples Survey (HPS) of 13,534 ethnic Thai and minority women living in highland villages near the Thai-Burma border.

Principal Findings: Women’s odds of giving birth in a hospital are lowered by 90% when they do not have citizenship (p<0.001), 39% when they are of a minority ethnicity (p<0.01), 50% when they have not had any schooling—compared to having finished upper secondary school (p<0.001), 30% if Thai language is not spoken at home, and 49% if a minority language is spoken at home (p<0.001).

Conclusions: Maternal and child health disparities exist in Thailand, likely due to unequal access to and unequal utilization of obstetric care services between women of different ethnicities, legal statuses, education levels, and language abilities.

Implications for Policy, Delivery, or Practice: Cultural competence and language services in hospitals must improve. Additionally, policies improving education access, healthcare coverage, and citizenship are important for addressing healthcare disparities.

Research Objective: Although breast cancer is amenable to screening, many women are diagnosed at advanced stages, when prognosis is least favorable. We examine the occurrence of advanced stage cancer in Ohio, in a multi-level context. We hypothesize that 1) area-level attributes are associated with advanced-stage breast cancer diagnosis, even after adjusting for individual-level characteristics; and 2) there are significant cross-level (individual- by area-level socioeconomic measures) interactions.

Study Design: We used 2005-2009 data from the Ohio Cancer Incidence Surveillance System (OCISS). Demographic characteristics (age, race, and marital status), as well as cancer stage (local, regional, distant, and unknown-stage/unstaged (U/U) cancer) were retrieved from the OCISS. Using geocoded patient’s residence address, we obtained data from the 2005-2009 American Community Survey on poverty, educational attainment, employment, and female-headed households at each of the census block group and census tract levels. Because we approximated the census block group-level measures to that of the individual, we referred to them as individual-level socioeconomic measures. We used census tract-level measures to reflect area-level measures. Furthermore, we identified patients according to their residence in various types of county (Appalachian/Rural, Metro, and non-
Metro counties) and in areas/populations that are federally-designated as Medically Underserved Areas/Populations (MUA/MUP). Our outcome of interest was the occurrence of advanced-stage cancer (regional- or distant-stage, excluding the U/U cases). In addition to descriptive analysis, we conducted multivariable logistic regression models to identify individual- and area-level correlates of advanced-stage cancer after excluding U/U cancers. We employed multi-level logistic models using the HLM software (Scientific Software International, Inc., version 7) to account for the clustering of patients within census tracts.

**Population Studied:** Women residing in Ohio and diagnosed with incident breast cancer.

**Principal Findings:** Our study population included 40,112 women. The mean and median age were 62.8 years and 62, respectively. Nearly 60% were diagnosed with localized disease, while 4.38% had U/U cancer. Thirty six percent were diagnosed with advanced-stage cancer. The highest proportion of advanced-staged cancers was observed in women younger than 45 (47.4%) and the lowest proportion was observed in women 75-84 years of age (30.9%). Results from the multivariable models indicated that after excluding U/U cases, and compared to women 55-64 years of age, women younger than 45 years were 45% more likely to be diagnosed with advanced-stage cancer (adjusted odds ratio: 1.45, 95% Confidence Interval [CI]: 1.35, 1.58). Advanced-stage cancer was also significantly independently associated with African-American race (1.29 (1.17, 1.44)); being married (0.90 (0.86, 0.95)); being in the highest poverty quartile both at the individual- and the area-level (1.12 (1.02, 1.23), and 1.20 (1.12, 1.30), respectively)); and with residing in MUA/MUPs (1.13 (1.07, 1.20)). Similarly, lower area-level education and employment, as well as higher proportions of female-headed households were positively associated with advanced cancer stage. We detected no cross-level interactions, however.

**Conclusions:** Area-level attributes accounted for in this study are significantly associated with advanced-stage breast cancer at diagnosis, even after adjusting for individual-level characteristics.

**Implications for Policy, Delivery, or Practice:** The findings highlight the importance of the place of residence relative to cancer stage and carry significant implications for targeted screening efforts.

**Political Ideology and Health: An Investigation into the Nature of Political Endorsement of Healthy Individuals**

Sanjeev Kumar, Yale School of Public Health; Jason Fletcher, Yale School of Public Health; Elizabeth Bradley, Yale School of Public Health

**Presenter:** Sanjeev Kumar, Ph.D., Postdoctoral Fellow, Department of Health Policy and Management, Yale School of Public Health, sanjeev.kumar@yale.edu

**Research Objective:** The aim of this study was to examine the association between self assessed health (SAH) and endorsement of conservative political ideology. Although previous research has identified many correlates of political ideology, we could find no study that has evaluated the association between self-assessed health (SAH) and political ideology. Information from this study could be useful to understand how health could be a factor in inducing policy volatility over time in social welfare and health promoting programs, through its impact on citizen’s political ideology.

**Study Design:** We used the National Longitudinal Study of Adolescent Health dataset, a longitudinal study of a nationally representative sample of 7th-12th grade students (N=20,745) surveyed through their 30s (N=15,701). We used data on SAH from Wave 1 (1994-1995) and changes in SAH from Wave 1 to Wave 3 (2001-2002). Our outcome was reported political ideology in Wave 4 (2008). We measured change in SAH using a 3-level variable indicating positive change (from not excellent to excellent health), no change, or negative change (from excellent to not excellent health). Political ideology was measured with an item with 5-point scale, which we dichotomized into very conservative (=1) versus other (=0). We used multivariate logistic regression to estimate the adjusted association between SAH (and change in SAH) and subsequent political ideology after controlling for state and cohort fixed effects, sex, race, income, assets, education, home ownership, weight at birth, cognitive score, health insurance status, and education and working status of mother.

**Population Studied:** A total of 13,034 had complete data in Waves 1, 3, and 4. Of these, 46 were eliminated due to missing sampling
weights and 227 were eliminated due to missing information on the state of residence, resulting in a final analytic sample of 12,061 individuals. **Principal Findings:** In a multivariate analysis, having excellent SAH in Wave 3 was significantly associated with endorsement of very conservative political ideology in Wave 4 (adjusted odds ratio (AOR) 1.37, P-value (P) 0.03). Similarly, people who experienced a positive change in SAH between Waves 1 and 3 were more likely to endorse a very conservative ideology by Wave 4 (AOR 1.44, P 0.02). Women and people of Asian background were less likely to report being very conservative (Ps<0.05); home ownership, household income, religion, and health insurance status were not significantly associated with reported political ideology. **Conclusions:** People reporting excellent (compared with poorer) SAH status in their adolescence were more likely to have strongly conservative political ideology in their adulthood. People in excellent health during formative years may attribute their wellbeing to their own efforts rather than publicly financed social and health programs, a narrative which is consistent with more conservative ideology. **Implications for Policy, Delivery, or Practice:** The findings highlight that support for expansive social welfare and health promoting programs are more likely to be centered among people who have suffered from health problems as adolescents than people who considered themselves in excellent health during their formative years. A challenge for public policy is to engage people in excellent health in fostering political support for social welfare and health promotion programs. **Funding Source(s):** AHRQ

**Health Benefits Mandates and Their Potential Effects by Racial and Ethnic Groups: Measuring Disproportionalities among Insured Populations**

Shana Lavarrada, University of California, Los Angeles; Joy Melnikow, UC Davis; Jenny Kempser, UC San Diego; Ninez Ponce, UCLA; Sylvia Guendelman, UC Berkeley; Dominique Ritley, UC Davis; John Lewis, California Health Benefits Review Program

**Presenter:** Shana Lavarrada, Ph.D., M.P.P., Research Scientist and Director of Health Insurance Studies, Center for Health Policy Research, University of California, Los Angeles, shana@ucla.edu

**Research Objective:** The effect of mandated health benefits coverage on racial/ethnic (R/E) health disparities is generally unknown, due to the lack of reliable R/E data in the insured population. We present our method for estimating California’s R/E distribution in the insured population and examine the potential implications of health insurance benefit mandates on access to care for different racial/ethnic groups. **Study Design:** We applied R/E information about the insured population from the 2009 California Health Interview Survey (CHIS) to the California Health Benefits Review Program (CHBRP) Costa and Coverage Model, which identifies the market segments that comprise the California health insurance market. The CHBRP model distinguishes segments in the private sector by regulator (the Departments of Insurance and Managed Health Care) and group size (large, small or individual plans); and in the public sector by type coverage (CalPERS, Medicaid, CHIP). For each R/E group (Latinos, non-Latino whites, Asian Americans and Native Hawaiian /Pacific Islanders, African Americans, and Other single or multiple races), we constructed age- and gender-specific disproportionality measures by dividing the R/E distribution within each insurance market segment by the R/E distribution of the entire market. Coverage may vary considerably between these segments, thus mandates may affect segments differently. Mandated coverage for tobacco cessation treatment was used as an example. **Population Studied:** California’s insured population, including those enrolled in large and small group plans and policies, individual plans and policies, Medicaid, and CalPERS plans. **Principal Findings:** Within California’s insured population, R/E group representation is disproportional among the different market segments. Latinos constitute 31% of large group HMO plans, and 33% of the small group plans, but comprise 66% of nonelderly enrollees in Medi-Cal managed care (California’s Medicaid program). Non-Latino whites constitute 66% of the non-HMO individual policies, but only 45% of the large group HMO population, and 14% of the nonelderly Medi-Cal managed care group. Males (both Latino and non-Latino white) were overrepresented in large group non-HMO plans. African Americans comprised 11% of Medi-Cal
managed care, but 2% of large group non-HMO plans. A public health impact analysis of a bill mandating tobacco cessation coverage illustrated that these disproportionalities have differential impacts by R/E group depending on the level of coverage already existing in that market segment. Since the individual market had the lowest rate of pre-existing coverage for tobacco cessation treatment, the projected impact of the mandate would disproportionately benefit non-Latino whites by providing more coverage that brings their insurance benefits up to par with the other market segments.

**Conclusions:** The disproportional effects of health insurance benefit mandates on access to care by R/E can be evaluated using available demographic and health insurance market data. For the specific bill examined, the largest gains accrued to the mostly non-Latino white individual market.

**Implications for Policy, Delivery, or Practice:** Because of R/E disproportionality by market segment, policymakers should be aware that benefit mandates will likely affect some market segments more than others and may have unintended consequences (both positive and negative) on R/E disparities.

**Racial, Ethnic, and Linguistic Disparities in Patients' Experiences and Diabetes Control in Community Health Centers**

Lucinda Leung, UCLA Ronald Reagan Hospital; Arturo Vargas-Bustamante, UCLA School of Public Health; Ana E. Martinez, UCLA Center for Health Policy Research; Xiao Chen, UCLA Center for Health Policy Research; Hector P. Rodriguez, UCLA School of Public Health

**Presenter:** Lucinda Leung, MD, MPH, Resident, Pgy-2, Internal Medicine, UCLA Ronald Reagan Hospital, lleung@mednet.ucla.edu

**Research Objective:** Racial, ethnic and linguistic disparities are known to exist in diabetes control and patient experience of care in the insured patient population. Few research studies, however, have examined racial, ethnic and linguistic disparities in patient experiences of care and diabetes control exclusively in safety net clinics. Community health centers (CHCs) primarily serve low-income and racial/ethnic minority patients with high incidence of diabetes; they often face resource constraints and lack the infrastructure to measure clinical quality of care. We aim to examine racial, ethnic and language disparities in patients' experiences of care and glycemic control among CHC patients.

**Study Design:** Observational cross sectional study. We analyzed early intervention patient survey data in fourteen clinics participating in a comparative effectiveness demonstration project in CHCs. Patients' experiences of care were assessed using the Clinician and Group CAHPS survey core composites: clinician-patient communication and access to care. Patient-reported diabetes control using HA1c and a hypoglycemia measure and self-management support using the PACIC-11 were also assessed. Patient covariates include socioeconomic and demographic characteristics (age, gender, education, race/ethnicity, language, health status, comorbidities). We conducted multivariable analyses, including controlling for patient sociodemographic and clinical characteristics and cluster adjustment by clinic. In order to understand the extent to which disparities between groups can be explained by modifiable factors, decomposition technique was used to parse out differences into observed and unobserved components.

**Population Studied:** Patients with type II diabetes mellitus (n=1203) from California CHCs.

**Principal Findings:** HA1cs were the following: 7.3 (5.7 to 10.8) for non-Latino Whites; 6.9 (5.5 to 11.9) for Chinese-speaking Asians; 7.7 (5.8 to 11.8) for English-speaking Latinos. Unadjusted scores (0-100 scale) on CG-CAHPS communication, CG-CAHPS access, PACIC, and hypoglycemia measures were respectively the following: 67.0, 51.9, 39.8, 72.9 for non-Latino Whites; 61.8, 51.4, 36.2, 80.3 Chinese-speaking Asians; 76.3, 57.5, 55.8, 72.1 English-speaking Latinos. Compared to English-speaking Latino patients, Chinese-speaking Asians patients in CHCs are more likely to have a lower HA1c (p<0.01, r^2=0.15); however, Chinese-speaking Asians are more likely to report worse experiences of clinician communication (p<0.001, r^2=0.11), worse access to care (p<0.01, r^2=0.23), and less receipt of patient-centered care and diabetes self-management support (p<0.02, r^2=0.13). Interestingly, non-Latino White patients in CHCs are also more likely to report lower satisfaction, particularly with provider communication (p<0.02, r^2=0.13) and diabetes patient-centered care (p<0.02, r^2=0.14). There were no disparities in hypoglycemic events after...
The Availability of Medical Oncologists and Timely Access to Adjuvant Chemotherapy for Patients with Stage III Colon Cancer

Anna Lin, American Cancer Society; Ahmedin Jemal, DVM, PhD, American Cancer Society; Elizabeth Ward, PhD, American Cancer Society

Implications for Policy, Delivery, or Practice: Given that decomposition analyses did not reveal many observable factors that explain disparities, more research on developing culturally and linguistically appropriate interventions for Chinese-speaking Asians are needed. Further inquiry is warranted to clarify the determinants of disparities seen between non-Latino Whites and Latinos in CHCs.

Funding Source(s): AHRQ

Poster Session and Number: A, #250

Research Objective: Timely access to adjuvant chemotherapy after resection improves overall survival for stage III colon cancer patients. Previous studies found that colon cancer patients who were older, with comorbid conditions, not currently married, and with poorly differentiated tumor were less likely to receive timely access to adjuvant chemotherapy. However, to date, no study has examined whether uneven geographic distribution of medical oncologists may contribute to delay treatment. In this study, we explore the association between the availability of medical oncologists within the health service area (HSA) in which the patient resides and time to initiate adjuvant chemotherapy treatment.

Study Design: A retrospective analysis of linked Surveillance, Epidemiology, and End results (SEER) – Medicare database. Medical oncologists were identified by physician specialty code. HSAs are geographic areas where medical resources were distributed and used based on the analysis of travel patterns between counties for routine hospital care. Time to initiate chemotherapy is calculated from the date of curative surgery to the date of initiation of chemotherapy. Generalized estimating equations (GEE) analysis clustered by HSA was used to investigate the association between the availability of medical oncologists and time to initiate chemotherapy after adjusting for clinical and patient characteristics.

Population Studied: Patients diagnosed with first primary stage III nodes positive colon cancer between 2000 and 2005, aged 66 and older, with continuous, non-HMO, Medicare part A and B benefits, survived six months or more, underwent colectomy within three months of diagnosis and initiated adjuvant chemotherapy within six months.

Principal Findings: There were 5,805 stage III colon cancer patients who underwent colectomy and initiate chemotherapy during study period. 74.8% patients initiated chemotherapy within 56 days after surgery. 6.39% of the cohort resided in a HSA with no medical oncologists; 9.84% with one to three oncologists; 18.35% with four to eight oncologists; 65.43% with nine or more oncologists. After controlling for clinical and patient characteristics, the results of GEE analysis showed that the availability of medical oncologists was not statistically significant associated with timely access to adjuvant chemotherapy. Patients who were older than 70 years (p<.001), African American (p<.05), currently not married (p<.05), dually eligible for Medicare and Medicaid (p<.05), with more comorbid conditions (p<.01), diagnosed later than 2001 (p<.01), and residing in Northeast region (p<.05) had a decreased likelihood of receiving chemotherapy within 56 days.

Conclusions: Timely access to adjuvant chemotherapy for patients with stage III colorectal cancer was not associated with the geographic availability of medical oncologists.

Implications for Policy, Delivery, or Practice: Since this study did not find greater availability of medical oncologists could shorten time to access treatment, future researches are needed.
to determine other factors related to delay
treatment.

**Educational Attainment and Premature Mortality: An Analysis of Disparities in the United States and Implications for Health Care Policy**

Jacob Lippa, Institute for Healthcare Improvement; David Radley, PhD, MPH, Institute for Healthcare Improvement; Pamela Riley, MD, MPH, The Commonwealth Fund; Cathy Schoen, MS, The Commonwealth Fund

**Presenter:** Jacob Lippa, MPH, Senior Research Associate, Commonwealth Fund Health System Scorecard Project, Institute for Healthcare Improvement, jal@cmwf.org

**Research Objective:** The objective of this study was to measure disparities and geographic variation in premature mortality by educational attainment, using years of potential life lost (YPLL) as the main outcome measure.

**Study Design:** Using mortality data from the national vital statistics system (NVSS), we calculated national and state-level age-standardized rates (per 100,000) of YPLL before age 75 for the time period 2007 to 2009. We stratified our analysis by education and cause of death, both recorded on the death certificate, comparing rates among adults with a high school education or less to those having completed at least a four-year college degree.

**Population Studied:** Adults over age 25 in the United States.

**Principal Findings:** The rate of YPLL per 100,000 for the United States was 8,100. We found a threefold difference, however, between adults with a four-year college degree (3,951) and those with, at most, a high school education (12,846). In all states, the rate of YPLL among the less-educated group is at least twice that of the college-educated.

Among the college-educated cohort, rates are strikingly similar across states (median 3,922; interquartile range 792). Conversely, rates vary widely among the less-educated group, ranging from 8,561 to 17,892 across states; rates are lowest in the Northeast and upper Midwest and highest in the South. In 27 states, YPLL for the less-educated group is more than 50 percent higher than the lowest state.

Cancers (27%) and cardiovascular disease (24%) account for the greatest share of total YPLL, followed by external causes (20%) such as motor vehicle accidents, assaults, and suicides. Comparing the two education groups, we found a two to fourfold difference within each of these causes of death; no one source accounted for the disparities by education.

**Conclusions:** A strong association exists between educational attainment and risk of premature mortality, as measured by YPLL. No one cause of death accounts for the disparity. Looking across states, premature mortality rates are strikingly similar for college-educated populations but vary widely for those with a high school education or less. Indeed, most of the variation in YPLL across states is driven by differences in years of life lost among the latter, less-educated, group.

**Implications for Policy, Delivery, or Practice:** Our findings indicate that reducing premature mortality and improving population health will require a particular focus on those at risk due to lower socio-economic status, as measured by education. The scheduled health insurance expansions, including the Medicaid expansions, offer a historic opportunity to reduce the observed disparities across and within states by improving access to primary care and holding care systems accountable for better health and care experiences for vulnerable populations. However, improving population health will likely require a community and population health approach, given the pervasive underlying disparities in causes of death. The state variation among vulnerable populations indicates substantial opportunity to improve with such a strategic approach.

**Racial/Ethnic Disparities in Preventive Care Practice**

Huabin Luo, Mount Olive College; Xinzhi Zhang, MD, PhD, University of Alabama at Birmingham; Bei Wu, PhD, Duke University

**Presenter:** Huabin Luo, Ph.D., Associate Professor, Management/Health Care, Mount Olive College, hluo@moc.edu

**Research Objective:** The 2003 Institute of Medicine (IOM) report defines a disparity as a difference in treatment provided to members of different racial or ethnic groups that is not justified by the underlying health conditions or
treatment preferences of patients. To implement IOM definition of disparity, the objectives of this study were: 1) To assess racial/ethnic disparities in use of eight preventive care practices among U.S. nursing home residents in 2004. 2) To evaluate the trends of disparity in pneumococcal and influenza vaccination in the past decades.

**Study Design:** Data used in this study are from the National Nursing Home Survey (NNHS) in 1995, 1997, 1999, and 2004. First, using 2004 NNHS data, we assessed use of eight preventive care services among white, black and other race/ethnicity residents, including influenza and pneumococcal vaccination, scheduled toilet plan/bladder retraining, pain management, behavioral problem management, skin/wound care, continence management, and restorative care. Second, we evaluated the trend of disparity in having influenza and pneumococcal vaccination (available in all the four NNHS). We implemented the IOM definition of disparity of care and used the rank-and-replace adjustment method (Cooks et al. 2012, HRS, 47(3):1232-54) to create a counterfactual resident population of black or other races/ethnicities to approximate the distribution of health status of the white residents. Data were analyzed using Stata 11.

**Population Studied:** National representative samples of nursing home residents in 1995, 1997, 1999, and 2004 NNHS.

**Principal Findings:** The 2004 NNHS data show significant differences in receipts of four of the eight preventive care practices examined. White residents were more likely to have pain management (6.71% vs. 3.53%, p<0.001), scheduled toilet plan/bladder retraining (34.26% vs. 25.03%), influenza vaccination (77.09% vs. 67.95%, p<0.001), and pneumococcal vaccination (56.31% vs. 43.31%, p<0.001) than black residents. White residents were also more likely to have scheduled toilet plan/bladder retraining (34.26% vs. 21.94%, p<0.001) than residents of other race/ethnicity. The overall trends of disparity in receipt of influenza vaccination and pneumococcal vaccination were not significant from 1995 to 2004. However, significant white-black disparity in receipt of influenza vaccination was found in 1997 and 2004 NNHS (p<0.01), and significant white-black disparity in pneumococcal vaccination was found in 1997, 1999, and 2004 NNHS (p<0.001).

**Conclusions:** Racial/ethnic disparities in preventive care among nursing home residents are still persistent.

**Implications for Policy, Delivery, or Practice:** It is critical to developed targeted interventions to improve quality of preventive care for minority residents in nursing home.

### Impact of Medical and Psychiatric Comorbidity Burden and Mortality in Veterans with Type 2 Diabetes

Cheryl Lynch, Ralph H Johnson Veterans Affairs Medical Center; Mulugeta Gebregziabher, PhD, Medical University of South Carolina; Kelly J Hunt, PhD, Medical University of South Carolina; Yumin Zhao MS, Ralph H Johnson Veterans Affairs Medical Center; Leonard E Egede, MD, MS, Ralph H Johnson Veterans Affairs Medical Center

**Presenter:** Cheryl Lynch, M.D., M.P.H., Assistant Professor Of Medicine, Medicine, Ralph H Johnson Veterans Affairs Medical Center, cheryl.lynch@va.gov

**Research Objective:** Multimorbidity, or the presence of multiple chronic diseases, is a major problem in clinical care with burdens such as higher risk of depression, lower quality of life, poorer physical functioning, and higher healthcare utilization and costs. Studies have shown greater disease burden measured by number of comorbid conditions is associated with poor clinical outcomes and increased morbidity for a variety of chronic diseases. However, few studies have examined the incremental effect of medical and psychiatric comorbidity burden on mortality in adults with type 2 diabetes. Therefore, we examined the specific question of which types of comorbidities, medical or psychiatric, drives differences in outcomes as well as the impact of individual comorbidities.

**Study Design:** Cox regression methods were used to analyze data from a linked database of multiple patient and administrative files. Diabetes and medical and psychiatric comorbidities were defined using ICD-9 codes based on validated algorithms.

**Population Studied:** A national cohort of 629,563 veterans with type 2 diabetes followed until death, loss of follow up, or study end.

**Principal Findings:** Hypertension (78%) and depression (13%) were the most prevalent medical and psychiatric comorbidities, respectively. Of the medical and psychiatric comorbidities examined, congestive heart failure...
(sample prevalence of 11.2%) and substance abuse (sample prevalence of 3.9%) carried the greatest mortality risks (HR=1.92; 95% CI 1.89-1.95 and HR=1.50; 95% CI 1.46-1.54, respectively). In unadjusted Kaplan-Meier survival curves, within each strata of psychiatric comorbidity burden the probability of survival was highest in those with no medical comorbidity. However, within each strata of medical comorbidity similar probabilities of survival were shown across different levels of psychiatric comorbidity. In adjusted regression analyses, the mortality hazard associated with having a single psychiatric comorbidity, compared to zero comorbidities, remains constant across all levels of medical comorbidities (respective HR 1.23, 95% CI 1.14-1.32 and HR 1.24, 95% CI 1.22-1.27) in veterans from zero up to 3+ medical comorbidities. In contrast, compared to zero psychiatric comorbidities, the mortality hazard associated with having 2+ psychiatric comorbidities decreases from 1.69 (95% CI 1.47-1.94) in veterans with zero medical comorbidities to 1.38 (95% CI 1.32-1.43) in veterans with 3+ medical comorbidities.

**Conclusions:** Multi-morbidity with respect to medical as well as psychiatric disorders is a significant predictor of mortality among veterans with type 2 diabetes. After adjusting for demographic factors, there is a clear graded relationship between an increasing number of medical and an increasing number of psychiatric comorbidities and increased mortality risk. However, the threshold at which the comorbidity burden becomes significant occurs at having two medical comorbidities or a single psychiatric comorbidity.

**Implications for Policy, Delivery, or Practice:** These findings suggest greater emphasis is needed on recognizing mental health issues earlier in the course of chronic physical conditions and of targeting psychiatric comorbidities in patients with a lower burden of medical comorbidity.

**Poster Session and Number:** A, #254

---

**Presenter:** Lisa Marceau, MPH, Vice President, Media and Communications, , New England Research Institutes, lmarceau@neriscience.com

**Research Objective:** Disparities in access to traditional health care have been extensively documented: some 90 million lack ready access to health care (45 million are uninsured, as many again underinsured). Disparities have traditionally reflected inability to access a physical entity (doctor’s office, clinic, hospital) by selected population groups lacking adequate health insurance. With increased availability of high-speed internet, many can go online for their health care: 65% of adults seek health information online and 35% use the internet for diagnosis. Some suggest a new era of electronic or digital medicine is emerging (ubiquitous smartphones, bandwidth, connectivity, social-networking) providing easier web access to a virtual health care system, promising a reduction of pervasive health care disparities. While some gaps in internet connectedness have narrowed over the past decade, demographic disparities still exist, particularly for the elderly, Hispanics and lower SES. We identify disparities in digital connectivity, and question whether a new era of electronic medicine will bring the promised reduction in health care disparities.

**Study Design:** The BACH Survey is a community-based random sample survey of men and women from Boston, Massachusetts. Participants aged 30-79 at baseline (2002-2005) were followed approximately 5- (2006-2010) and 7- (2010-2012) years later.

**Population Studied:** BACH is racially/ethnically diverse with distribution of race/ethnicities at the second follow-up of: Black: 1,026; Hispanic: 1,036; White: 1,093. Sociodemographics, healthcare access/utilization, lifestyle/behavior, health status, internet connectivity, and other measures were collected.

**Principal Findings:** Having a home computer, home internet connection, and access to a computer somewhere other than home differed significantly by race/ethnicity (p<.001 for all). Whites (84.7%) were more likely than Blacks (72.1%) or Hispanics (65.2%) to have a desktop or laptop computer. Whites (82.4%) were more likely to have an internet connection at home than Blacks (65.3%) and Hispanics (58.9%). Hispanic participants were least likely to access a computer outside their home (30%), compared with Black (64.0%) and White (64.6%) subjects. There were racial/ethnic differences in whether
Participants had a smartphone (p=0.02) with Black participants more likely to report that they had one than White participants (35.2% vs. 33.1%) and Hispanics (21.9%). Males (36.5%) were more likely to report having access to a smartphone than females (28.6%) (p=0.012), and were more likely to access a computer at work (p=0.005).

**Conclusions:** These results suggest internet connectedness mirrors existing patterns of racial/ethnic and SES disparities in access to the traditional health care system. It therefore appears the emerging era of electronic medicine and digital access may not achieve the promised reduction in health care disparities.

**Implications for Policy, Delivery, or Practice:** Efforts over several decades to reduce worrisome disparities in accessing traditional medical care have had limited success. Providing wider population coverage with health insurance may not reduce disparities in an era of electronic medicine. Persistent health care disparities in the era of electronic medicine will almost certainly require novel new models to explain utilization behavior, and innovative approaches to reach the underserved. The imminence of electronic medicine is not widely recognized by researchers and planners, and health services research will need to employ different intervention strategies and adaptive methods to measure their effectiveness.

**Variations in the Diagnosis and Quality of Care for Pain by Primary Care Physicians: Results from a Factorial Experiment**

Nancy Maserejian, New England Research Institutes; Felicia Trachtenberg, PhD, New England Research Institutes; Michael Fischer, MD, Brigham and Women's Hospital; Jeffrey Katz, MD, MSc, Harvard Medical School and Brigham and Women's Hospital; Jing Yu, MS, New England Research Institutes; Lisa Marceau, MPH, New England Research Institutes; John McKinlay, PhD, New England Research Institutes

**Presenter:** Nancy Maserejian, Sc.D., Senior Research Scientist and Associate Director, Epidemiology, Department of Epidemiology, New England Research Institutes, nmaserejian@neriscience.com

**Research Objective:** Pain management decisions have been shown to vary by sociodemographic characteristics of patients and providers, and differences exist in the prevalence of diagnosed pain conditions by patient race/ethnicity, sex, age, and socioeconomic status (SES). The objective of this experiment was to disentangle characteristics such as patient SES and race to test the hypothesis that patient, physician, and practice organizational factors influence clinical decision-making for pain conditions.

**Study Design:** Randomized factorial experiment. Physician subjects viewed two clinically-authentic videos of patients (actors) presenting with pain either as undiagnosed sciatica symptoms or diagnosed knee osteoarthritis. Patient gender, SES, and race (white, black, Hispanic), and physician gender and experience (<10 years vs. => 10 years in practice) systematically varied, permitting estimation of unconfounded effects. Analysis of variance was used for outcomes of physician decision-making, including diagnosis of sciatica and pain management (test ordering, behavioral counseling, prescriptions, referrals).

**Population Studied:** Purposeful sample of 192 U.S. primary care physicians from 2010-2012 to fill design cells of gender and experience.

**Principal Findings:** Most (93.7%) physicians appropriately diagnosed sciatica, but there was considerable variation in pain treatment decisions largely unexplained by patient race, gender or provider gender. The treatment of lower vs. higher SES patients with sciatica symptoms were generally similar, e.g., x-ray (55% vs. 49%, P=0.4), MRI (32% vs. 35%, P=0.7), exercise counseling (33% vs. 32%, P=0.9), and referrals (20 vs. 23%, P=0.6). However, lower SES patients less frequently received narcotics for sciatica (52.1% vs. SES 68.7%, P=0.01). Patient race had no impact on management of the sciatica patient, yet for the osteoarthritis patient, whites were more likely to receive narcotics (47%, vs. blacks 27%, Hispanics 33%; P=0.03), with no significant interaction with SES. Findings were also similar by gender (e.g., narcotics for 63% of females, 57% males, P=0.3), with the exception of muscle relaxants, which were more frequently prescribed for females (57% vs. 36%, P=0.002). Physicians in practice <10 years (vs. =>10 years) ordered fewer tests, particularly basic lab work or urinalysis, were more likely to prescribe NSAIDs for pain relief, and to provide advice on lifestyle, particularly exercise (P<=0.01). MRI for osteoarthritis pain was more commonly used by physicians who reported not using clinical...
practice guidelines (21% vs. 13%, P=0.04). Overall test ordering decreased as organizational emphasis on business or profits increased.

Conclusions: We observed inconsistent results between the two pain conditions regarding whether prescription of narcotics was affected by race or SES. Since the same physicians viewed both scenarios, physicians may be differentially influenced by race vs. SES depending on the situation. Additional research is warranted to identify cognitive processes underlying physician variations in pain management.

Implications for Policy, Delivery, or Practice: The finding that physicians' length of time in practice, as well as organization emphasis on business, influences pain management decisions indicates a need for the systematic implementation of quality measures. Policy-makers should also develop methods to assure that narcotic analgesics, when appropriate, are prescribed and monitored for patients of various races and socioeconomic levels.

Pregnancy Intention and Use of Birth Control among Hispanic Women in the United States: Data from the National Survey of Family Growth, 2006-2010
Melissa A. Simon, Department of Obstetrics and Gynecology and Preventive Medicine, Northwestern University; Lisa Masinter, Northwestern University; Joe Feinglass, Department of General Internal Medicine, Northwestern University

Presenter: Lisa Masinter, M.D., M.P.H., Fellow, Center for Healthcare Studies, Northwestern University, lisa.masinter@northwestern.edu

Research Objective: Hispanic women have the highest fertility rate, the highest unintended birth rate and the highest teenage birth rate in the United States. The goal of this study is to further characterize the rates of pregnancy, childbearing and contraceptive use in this population.

Study Design: We performed a cross sectional analysis of the 2006-2010 National Survey of Family Growth (NSFG). In self-identified Hispanic respondents, we assessed the relationship between ever having a pregnancy or live birth and social, demographic and cultural characteristics, including age, education, income, marital status, immigration status, preferred language and country of origin. We obtained the proportion of pregnancies from those respondents that were identified as intended or unintended as well as the outcomes of those pregnancies. We also determined the proportion of unintended pregnancies associated with contraceptive use during the month of conception, specific contraceptive methods employed, and reasons expressed for having had an unintended pregnancy. Descriptive statistics were obtained with Stata Version 12 (College Station, TX) and findings are nationally representative estimates based on weights provided by the NSFG.

Population Studied: A total of 2723 self-identified Hispanic women, aged 15-44, were included and 983 of their pregnancies were examined. The NSFG only asked questions about contraceptive use prior to unintended pregnancy for pregnancies within three years of the interview. Therefore, we limited our pregnancy analysis to the same time period.

Principal Findings: Almost 70% of Hispanic women reported ever having been pregnant, including 96% of women over the age of 35. Among teenagers, ages 15-19, approximately 18% reported having had at least one pregnancy. Being married, Catholic or an immigrant, having a lower socioeconomic status, and speaking Spanish were associated with a higher likelihood of pregnancy or live birth (p.<0.05). Mexican women did not differ from other Hispanic subgroups. Half (51%) of Hispanic pregnancies were described as unintended, including 81% among teenagers. Of those, 15% ended in elective abortion and 53% ended in live birth, although abortions are likely underreported. Contraceptive use during the month of conception occurred in 50% of unintended pregnancies with no differences noted among the different socio-cultural variables. The most common methods used were oral contraceptives, patch, or ring (22%), condoms (21%) and withdrawal (16%). The most frequent reason for unintended pregnancy despite contraception was “improper use” (45%). and the leading reason for not utilizing contraception prior to an unintended pregnancy was “I did not think I could get pregnant.” (37%).

Conclusions: In Hispanic women, half of all pregnancies are unintended and over 80% of teenage pregnancies are unintended. Over 40% of unintended pregnancies that occurred while using contraception were due to improper use and almost 40% of pregnancies with no
Implications for Policy, Delivery, or Practice: These findings demonstrate the critical need for improved education and counseling strategies about reproductive health and contraception in the Hispanic population.

The Effects of Patient Medication Requests on Physician Prescribing Behavior: Results from a Factorial Experiment

John McKinlay, New England Research Institutes; Felicia Trachtenberg, PhD, New England Research Institutes; Lisa Marceau, MPH, New England Research Institutes; Jeffrey Katz, MD, MSc, Harvard Medical School and Brigham and Women's Hospital; Michael Fischer, MD, Brigham and Women's Hospital

Research Objective: Because of exposure to pharmaceutical advertising in different media outlets, especially direct to consumer advertising (DTCA), as well as suggestions from family and friends, patients are increasingly activated to request a specific medication during an encounter with a physician. To estimate the effect of patient requests for specific medications on physician prescribing behavior, unconfounded by selected patient attributes (age, race/ethnicity, SES), physician characteristics (gender, experience) and many practice setting factors.

Study Design: Balanced factorial experiment using two clinically authentic video-based scenarios; an undiagnosed “patient” with symptoms strongly suggesting sciatica, and a “patient” with already diagnosed chronic osteoarthritis of the knee. Half of the patients with sciatic symptoms specifically requested oxycodone, while the other half simply requested something to help with pain. Similarly, half of those with knee osteoarthritis specifically requested Celebrex.

Population Studied: Community-based primary care physicians from several different U.S. states were recruited as experimental subjects (n=192)

Principal Findings: The primary outcome was whether physicians would accede to a patient request for a specific medication. Alternative pain medications that would be prescribed were secondary outcomes. 19.8% of the sciatic patients specifically requesting oxycodone would receive a prescription, compared with just 1% of those making no request (p=0.001). 53% of patients with knee osteoarthritis requesting celebrex would receive it, compared with 24% of patients making no specific request (p=0.001). Assertive patients requesting oxycodone were more likely to receive a strong narcotic (p=0.001) and less likely to receive a weak narcotic (p=0.01), or an NSAID. Assertive patients requesting celebrex were much less likely to receive a narcotic (p=0.008), or an NSAID. None of the patient attributes, the physician characteristics or the organizational factors influenced a physician’s willingness to accede to a patient request for a specific medication.

Conclusions: Patients making a request for a specific medication are highly likely to have it prescribed, with the high likelihood of receiving the requested medication consistent across the two scenarios. Who the patient and physician are, and numerous features of the practice setting in which the encounter occurs, have no effect on the success of a medication request.

Implications for Policy, Delivery, or Practice: This study suggests that the impact of activated patients on physician decisions potentially increases the total number of patients who become activated and make specific requests of their physicians. Our findings indicate that these requests are often likely to succeed. Since DTCA is used exclusively for expensive medications, generally those like celecoxib that are still available only in branded forms, this effect is likely to increase medication costs.

Nonsteroidal Anti-inflammatory Drug [NSAID] Risk Awareness: Results of a Shared Decision-Making Intervention

Michael J. Miller, The University of Oklahoma College of Pharmacy; Michael Miller, The University of Oklahoma; Jeroan J. Allison, University of Massachusetts Medical School; Daniel J. Cobaugh, American Society of Health-System Pharmacists Research and Education Foundation; Midge N. Ray, The University of Alabama at Birmingham Department of Health Services Administration; Kenneth G. Saag, The University of Alabama at Birmingham Center for Education & Research on Therapeutics of Musculoskeletal Disorders

Nonsteroidal Anti-inflammatory Drug [NSAID] Risk Awareness: Results of a Shared Decision-Making Intervention

Michael J. Miller, The University of Oklahoma College of Pharmacy; Michael Miller, The University of Oklahoma; Jeroan J. Allison, University of Massachusetts Medical School; Daniel J. Cobaugh, American Society of Health-System Pharmacists Research and Education Foundation; Midge N. Ray, The University of Alabama at Birmingham Department of Health Services Administration; Kenneth G. Saag, The University of Alabama at Birmingham Center for Education & Research on Therapeutics of Musculoskeletal Disorders
**Presenter:** Michael Miller, Dr.P.H., M.Pharm., B.S.Pharm., Associate Professor, College of Pharmacy, The University of Oklahoma, michael-miller@ouhsc.edu

**Research Objective:** Although NSAID risks are well-appreciated in the medical community, improving patient risk awareness remains a challenge. Isolated patient-based or provider-based interventions may produce, at best, modest change. The partial success of single-focus interventions has led to interest in combined approaches that include patient activation and shared decision-making between patient and physician. While the literature is replete with complex, multi-modal interventions aimed at changing patient behavior, there is little to guide researchers on the incremental impact of simple, direct interventions to improve patient risk awareness and safety. Few studies have focused on direct-to-patient approaches to improve patient safety. Therefore, the objective of this research was to test whether a combined patient- and physician-based intervention contributed to increased patient-reported awareness of any prescription or over-the-counter (OTC) NSAID risk.

**Study Design:** A group randomized trial was used to promote patient-physician communication about NSAID risks between June 2005 and February 2007. Cross-sectional data were collected from different patients at baseline and after the intervention. Intervention physician practices were randomly assigned to receive a combination of continuing medical education (CME) about NSAIDs and patient activation tools designed to promote personal risk assessment and communication during the clinical encounter. Control physician practices received only CME about NSAIDs. The primary outcome measure was self-reported patient awareness of any problems or risks with either prescription or OTC NSAIDs. A multivariable logistic Generalized Linear Latent and Mixed Model was used to collectively test the relationship between the intervention, study phase, intervention study phase interaction, and primary study endpoint while controlling for differences in patient characteristics in the baseline and follow-up phases.

**Population Studied:** 347 eligible adult patients 65 years or older at baseline and 355 eligible adult patients 50 years or older at follow-up were recruited from 39 physician practices in the Alabama Practice-Based Network. The age criterion was relaxed at follow-up to ensure adequate enrollment.

**Principal Findings:** In multivariable analyses, the intervention was not associated with patients reporting awareness of any prescription NSAID risk [(Adjusted Odds Ratio [AOR]=0.74, p=0.100]. Whereas, patients participating in the follow-up study phase had significantly higher odds of reporting awareness of any prescription NSAID risk [(AOR=1.52, p=0.053] as did those patients with at least some college education [(AOR=1.78, p=0.001]. Patients reporting black race had significantly lower odds of reporting awareness of any prescription NSAID risk [(AOR=0.59, p=0.008]. A similar pattern of relationships was observed for the endpoint defined as patients reporting awareness of any OTC NSAID risk. The intervention study phase interaction term was not significant and removed from final analysis.

**Conclusions:** While the point of care intervention encouraging patient activation and shared decision-making did not have an observed effect, there was an increase in the percentage of patients from physicians in private, community-based practice in Alabama self-reporting awareness of any prescription or OTC NSAID risk during the study period. Significant racial and educational disparities in NSAID risk awareness were observed.

**Implications for Policy, Delivery, or Practice:** Future interventions should be designed to target racial and educational disparities related to NSAID risk awareness observed in this research.

**Patient Risk Knowledge about Nonsteroidal Anti-inflammatory Drugs [NSAIDs]: Evaluating the Impact of a Patient Storytelling Intervention**

Michael J. Miller, The University of Oklahoma College of Pharmacy; Michael Miller, The University of Oklahoma; Robert Weech-Maldonado, The University of Alabama at Birmingham Department of Health Services Administration; Ryan C. Outman, The University of Alabama at Birmingham Center for Outcomes and Effectiveness Research (COERE); Daniel J. Cobaugh, American Society of Health-System Pharmacists Research and Education Foundation; Lang Chen, The University of Alabama at Birmingham Center for Education & Research on Therapeutics of Musculoskeletal Disorders; Midge N. ray, The University of
Colon cancer was included because NSAIDs are associated with significant toxicity. Previous research has identified suboptimal as well as racial and ethnic differences in NSAID risk awareness, behavior, and communication with NSAID users. Given this understanding, practical interventions are needed to strengthen patient skills for medication self-management and communication to ensure optimal understanding of NSAID risks in vulnerable populations. Therefore, this research sought to evaluate the impact of a culturally-sensitive patient storytelling intervention for enhancing patient NSAID risk knowledge.

**Research Objective:** Despite common and frequent use, NSAIDs are associated with significant toxicity. Previous research has identified suboptimal as well as racial and ethnic differences in NSAID risk awareness, behavior, and communication with NSAID users. Given this understanding, practical interventions are needed to strengthen patient skills for medication self-management and communication to ensure optimal understanding of NSAID risks in vulnerable populations. Therefore, this research sought to evaluate the impact of a culturally-sensitive patient storytelling intervention for enhancing patient NSAID risk knowledge.

**Study Design:** A group randomized trial tested the effectiveness of a patient storytelling intervention in promoting NSAID risk knowledge among patients between March 2011 and March 2012. Thirty-six physician practices from the Alabama Practice-Based Continuing Medical Education network were randomly assigned to an intervention or control arm. Patients from the 18 practices in the intervention arm received an educational DVD with the intervention while the 18 practices in the control arm received usual care. All patients participated in a baseline and follow-up telephone interview 4 months after assignment. The 10-minute DVD included patient interviews and stories related to their experiences with NSAIDs, NSAID-related adverse effects, importance of communication with healthcare providers, and use of a medication list. Health educator informational segments were integrated to reinforce important points. Prior to deployment, the DVD was reviewed by an expert multidisciplinary panel of healthcare providers and pilot-tested with actual patients. The primary outcome was a composite measure of knowledge as to how the use of NSAIDs may affect 5 conditions (i.e., colon cancer, high blood pressure, kidney disease, stomach/intestinal disease, and heart attack). Colon cancer was included because NSAIDs are associated with a protective effect while increasing the risk of the 4 other conditions.

**Population Studied:** A total of 259 patients [124 in the intervention and 135 in the control arm] were enrolled in the study and 233 remained at follow-up. Forty percent of the sample was African-American. Eligibility was determined from exit cards at the physician practice and included patients 19 years or older currently taking a prescription NSAID or over-the-counter ibuprofen or naproxen as recommended by their physician. NSAID use was verified at the time of interview.

**Principal Findings:** Intervention and control groups were comparable at baseline. Bivariable logistic regression analyses accounting for clustering of patients within physician practices revealed higher, but statistically nonsignificant, odds of overall or any improvement in NSAID risk knowledge for those who received and watched the educational DVD compared to the control group (Odds Ratio [OR]=1.45, p=0.29; OR=1.35, p=0.40, respectively). Whereas, those who received the DVD and did not watch the DVD had nearly identical odds of overall or any improvement in NSAID risk knowledge compared to the control group (OR=1.01, p=0.97; OR=0.96, p=0.92, respectively).

**Conclusions:** While showing promise, if watched, the educational patient storytelling intervention did not significantly improve NSAID risk knowledge.

**Implications for Policy, Delivery, or Practice:** Although simple and practical, the use of an educational DVD for the patient storytelling intervention may not realize it is full potential without more active encouragement of use from healthcare providers.

**The Quality of Surgical Care in Safety Net Hospitals: A Systematic Review**

Charles A. Mouch, BS, University of Michigan; Arden Morris, University of Michigan; Christy H. Lemak, PhD, University of Michigan; Scott E. Regebogen, MD, MPH, University of Michigan; Sandra L. Wong, MD, MPH, University of Michigan; Arden M. Morris, University of Michigan

**Presenter:** Arden Morris, M.D., M.P.H., Associate Professor, Surgery, University of Michigan, ammsurg@umich.edu
Research Objective: The quality of care in safety net hospitals (SNHs) is subject to frequent speculation based on conflicting data and small studies. We hypothesized that, on average, SNHs provide lower quality of care for surgery patients than non-SNHs.

Study Design: We performed a systematic review of the literature using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines with the PubMed, CINAHL, and Scopus online databases. Inclusion criteria were English language, publication in a peer-reviewed scientific journal between 1995-2012, analysis of primary or secondary data, study of surgical care in a hospital or system that met the Institute of Medicine (IOM) definition of a safety net hospital, location in the United States, and measurement of at least one of the IOM-designated domains of quality (Safety, Effectiveness, Efficiency, Timeliness, Patient Centeredness, and Equity). Studies of trauma care and rural hospitals were excluded. Each article was independently reviewed by at least two co-investigators. A data abstraction tool was used to record the eligibility, purpose, design, results, conclusion, and overall quality of each reviewed article. Disagreements over eligibility and data were resolved by group discussion. The main results and conclusions abstracted from the included articles were then analyzed and presented according to the quality domains most clearly addressed by each article.

Population Studied:

Principal Findings: Our initial search identified 1556 articles and resulted in a total of 18 studies that met all inclusion criteria. Articles that addressed Safety revealed conflicting data regarding the safety of surgical care in SNHs compared to non-SNHs. SNHs performed significantly lower in measures of Timeliness and Patient-centeredness within single institutions and when compared to non-SNHs. Several papers indicated statistically significant differences in Equity, both within individual SNHs and between SNHs and non-SNHs.

Conclusions: Although our results were mixed, many papers suggested a clear need for improvement in the quality of surgical care provided by SNHs. Given these data, SNHs may provide excellent testing sites for future quality improvement measures. Not only would improvements in quality be more readily appreciated in a SNH setting, but these measures would also provide a direct means of addressing health care disparities among the poorest, most underserved, and most vulnerable populations in the United States.

Implications for Policy, Delivery, or Practice:

Disparities in Hypertension control among African-American Men: Do Demographics, Disease Characteristics and Medication Adherence Explain Differences?

David Mosen, Kaiser Permanente Northwest; Adrienne Feldstein, MD, MPH, Kaiser Permanente Northwest; Center for Health Research; Nancy Louie-Lee, Rph, MS, Kaiser Permanente Northwest; Clinical Quality Support Services; Nancy Perrin, PhD, Kaiser Permanente Northwest; Center for Health Research; Delilah Moore PhD, Kaiser Permanente Northwest; Clinical Quality Support Services

Presenter: David Mosen, Ph.D., M.P.H., Senior Program Evaluation Consultant, Center for Health Research, Kaiser Permanente Northwest, david.m.mosen@kpchr.org

Research Objective: Poor blood pressure control is associated with increased morbidity and mortality. Previous research has found significant disparities in blood pressure control among African-American men, compared to white men. Little is known about what factors explain these disparities. The objective of this work was to determine: 1) whether disparities in blood pressure control exist among African-American men vs. white men and 2) whether demographics, disease characteristics, primary care utilization, use of hypertension medications and medication adherence explain differences in blood pressure control.

Study Design: Using an observational study design, we studied African-American (n=686) and white men (15,055) ages 45-85, with a diagnosis of hypertension (HTN) and a valid blood pressure (BP) measurement between 12/1/2010 and 11/30/2011. Patients received care in Kaiser Permanente Northwest (KPNW), a group model health plan, and maintained continuous enrollment in the 12 months prior to the BP measurement. Good BP control was defined as: 1) systolic value < 140 and 2) diastolic value < 90. We constructed a series of logistic regression models to assess the independent association of race (white vs. African-American) with blood pressure control,
adjusting for covariate measures assessed in the 12 months prior to BP measurement. These covariates include: age (45-64 vs. 65-85; as of BP date), income (continuous), body mass index (BMI), diabetes status (yes vs. no), chronic kidney disease (CKD) status (yes vs. no), primary care utilization (>= 1 visits vs. none), use of HTN medications (>= 1 dispensings vs. none) and medication adherence (>= 80% of HTN medication coverage in 12 months prior to BP date vs. < 80%). Seven logistic models were constructed: model 1 (race) + model 2 (model 1+ race and demographics [income, age]), model 3 (model 2 + BMI), model 4 (model 3 + diabetes status, CKD status), model 5 (model 4 + primary care utilization), model 6 (model 5 + use of HTN medications) and model 7 (model 6 + medication adherence).

**Population Studied:** African-American and white men (ages 45-85) with HTN diagnosis and valid BP measurement.

**Principal Findings:** Whites were more likely to have good BP control in unadjusted models (OR=1.70, 95% CI = 1.44-2.00; p < .0001). This point estimate remained consistent across all logistic models examined; even after adjusting for all covariate measures: demographics, disease status, primary care utilization, use of HTN medications and medication adherence (OR= 1.80, 95% CI = 1.50-2.15; p < .0001).

**Conclusions:** Our findings suggest that disparities in BP control among African-American men remain when compared to white men, even after adjusting for the influence of demographics, key comorbidities, and clinical and medication utilization.

**Implications for Policy, Delivery, or Practice:** Our results suggest further research is needed to explain disparities in BP control among African-American men v. white men. More work is needed to understand whether lifestyle choices, biological and other factors explain differences in BP control and whether targeted interventions can reduce these disparities.

**Has the VA Found a Way to Reduce Racial Disparities in Kidney Transplant Evaluation? Preliminary Results from the National VA Kidney Transplant Study**

Larissa Myaskovsky, VA Pittsburgh Healthcare System; John Pleis, VA Pittsburgh Healthcare System, Pittsburgh, PA; Mohan Ramkumar, VA Pittsburgh Healthcare System, Pittsburgh, PA; Anthony Langone, VA Tennessee Valley Healthcare System, Nashville, TN; Somnath Saha, Portland VA Medical Center, Portland, OR; Christie Thomas, Iowa City VA Healthcare System, Iowa City, IA

**Presenter:** Larissa Myaskovsky, Ph.D., Associate Professor, Center for Health Equity Research and Promotion, VA Pittsburgh Healthcare System, larissa.myaskovsky@va.gov

**Research Objective:** End-stage kidney disease is more common in African Americans (AA) and other minorities (OM) (e.g., Hispanic/Latinos) than Whites (WH). Reports from national data indicate that AA & OM are less likely to be evaluated for kidney transplant (KT), and when they do get evaluated, take significantly longer to complete evaluation than WH. Race disparities persist even after controlling for medical factors, and non-medical reasons for race disparities are poorly understood. Ours is the first multi-site, prospective study to recruit the majority of Veterans evaluated for KT within the National VA KT System. Preliminary results from our ongoing longitudinal study will (a) compare rates of evaluation and time to evaluation between AA, OM, and WH Veterans; and (b) show how cultural factors (e.g., perceived discrimination, medical mistrust), psychosocial characteristics (e.g., anxiety, depression), and transplant knowledge are related to time to complete transplant evaluation.

**Study Design:** Longitudinal study, in which patients completed telephone interviews after their first clinic appointment, and again after they were accepted or found ineligible for KT.

**Population Studied:** AA, OM, and WH end-stage kidney disease patients being evaluated for KT.

**Principal Findings:** AA (n=200) and OM (n=149) Veterans were younger, less educated, and less likely to be married than WH (n=272). AA and OM experienced significantly more healthcare discrimination, perceived more overall healthcare racism, had higher levels of medical mistrust, greater family loyalty, and more religious objections to KT than WH (all ps less than .05). WH had higher levels of KT knowledge, but were less likely to endorse external health beliefs than AA and OM. Despite these differences, we found no significant difference between groups in any other predictors or outcomes, including time to complete evaluation or proportion accepted for transplant. Age, preference for a living donor KT, education, private health insurance, and having
a potential living donor, predicted time to complete evaluation independently of race.  

Conclusions: We found expected race differences on demographic, cultural and psychosocial factors, but not in outcomes, across all 4 VA kidney transplant centers in the US (Iowa, Nashville, Pittsburgh, and Portland).

Implications for Policy, Delivery, or Practice: Because the procedures for KT evaluation in the VA are markedly different than those in non-VA settings, we believe that healthcare system factors may have contributed to reduced disparities in outcomes. Interventions to reduce disparities in kidney transplant should thus focus on system-level factors, such as altering transplant clinic procedures or methods of processing patients through the transplant evaluation process.

Cultural and Psychosocial Factors Predict Racial Disparities in Kidney Transplant Evaluation  
Larissa Myaskovsky, University of Pittsburgh, School of Medicine; John Pleis, VA Pittsburgh Healthcare System and University of Pittsburgh, Graduate School of Public Health; Mary Amanda Dew, University of Pittsburgh, School of Medicine; Galen E. Switzer, VA Pittsburgh Healthcare System and University of Pittsburgh, School of Medicine; Ron Shapiro, University of Pittsburgh, School of Medicine

Presenter: Larissa Myaskovsky, Ph.D., Associate Professor, Medicine, University of Pittsburgh, School of Medicine, larissa.myaskovsky@va.gov

Research Objective: African Americans (AA) wait significantly longer for, and are less likely to receive, a kidney transplant (KT) than Whites (WH). Race disparities persist even after controlling for medical factors, and non-medical reasons for race disparities are poorly understood. Data from our ongoing longitudinal study will show how cultural (e.g., perceived discrimination, medical mistrust) and psychosocial factors (e.g., anxiety, depression), and transplant knowledge contribute to race disparities in KT.

Study Design: Longitudinal study, in which patients completed telephone interviews after their first clinic appointment, and again after they were accepted or found ineligible for KT.

Population Studied: AA and WH end-stage kidney disease patients being evaluated for KT.

Principal Findings: AA (n=257) were younger, had lower incomes, were more likely to be on public insurance, and less likely to be married than WH (n=776). AA reported experiencing significantly more healthcare discrimination, perceived more overall healthcare racism, had higher levels of medical mistrust, greater family loyalty, and more religious objections to KT than WH (ps less than .01). WH had higher KT knowledge (p less than .001), engaged in more learning activities (p less than .01), and spent more time learning about KT than AA (p less than .05). While WH were more likely to accept a living donor volunteer (p less than .01), AA were more willing to ask for a live kidney donation (p less than .001). AA took 58% longer to complete transplant evaluation (p less than 0.001), were less likely to be accepted for transplant (p less than .001), and took significantly longer to be accepted for transplant (p less than .001) than WH. Demographics, cultural and psychosocial factors, and transplant knowledge predicted time to complete evaluation independently of race.

Conclusions: Interventions to address racial disparities in KT should incorporate non-medical risk factors in patients.

Implications for Policy, Delivery, or Practice: Suggestions for interventions include: fast-track evaluation for at-risk patients, increase contact with patients to ensure follow-through with necessary testing, facilitate scheduling of appointments, recruit former recipients as peer mentors, and enhance the cultural competency of transplant teams to learn about the reasons that patients may take longer to complete evaluation.

Effectiveness of Multicomponent Asthma Intervention for Children with Asthma from Low Income Families Living in East Harlem, New York City

Tursynbek Nurmaganbetov, Centers for Disease Control and Prevention; Veronica Uzoebo, NYC Department of Health and Human Hygiene; Roger Hayes, NYC Department of Health and Human Hygiene

Presenter: Tursynbek Nurmaganbetov, MS, MA, PhD, Senior Science Fellow, National Center for Environmental Health, Centers for Disease Control and Prevention, ten7@cdc.gov
Research Objective: To analyze the effectiveness of a multicomponent home environmental asthma intervention targeting children from low-income families in East Harlem, New York City.

Study Design: Three hundred eighty children with persistent asthma participated in the study. All families were assessed for baseline characteristics including asthma symptoms and health care utilization experienced by a child; presence of home environmental triggers; and parents’ knowledge and skills in managing the child’s asthma. Based on baseline characteristics and their consent, families were divided between intervention (200) and control (180) groups. Families were assigned a licensed asthma counselor who coordinated all specialized services as part of the intervention; services included asthma case management, home environmental assessment, and assistance with remediation of asthma triggers. The main asthma outcomes included in the study were the rates of emergency department visits (edv), hospitalizations (hsp), asthma symptom days (asd), school days missed (sdm), and work days missed (wdm) due to asthma. Observable baseline variables included age, gender, race, and baseline rates of edv, hsp, asd, sdm, and wdm. The effect of the intervention was measured as the difference in the main asthma outcomes at the baseline and at a post-intervention assessment. This was not a randomized control study. To reduce the influence of confounding factors we applied the propensity score method to estimate the effect of the intervention on the primary asthma outcomes.

Population Studied: Children aged 17 years or younger were referred to the study by hospitals or clinics following an emergency room visit or hospitalization, by school based clinics, or by day care centers. Families were included in this study if they completed an initial assessment to establish their baseline status and at least one follow-up questionnaire. All families were enrolled in the study between January 2008 and December 2010. All resided in East Harlem of NYC and had combined household incomes of $20,000 or less; about 63 percent of the sample lived in public housing. A majority of the families were Hispanic (55%) and Black (33%).

Principal Findings: Baseline main asthma outcomes were: 2.56 (intervention group) and 2.64 (control group) for edv, 0.44 and 0.62 for hsp, 7.35 and 5.86 for asd, 5.38 and 6.96 for sdm, and 6.95 and 3.57 for wdm. Based on the propensity score method, the average treatment effect of the intervention was 2.13 for edv, 0.92 for hsp, 2.67 for asd, 1.95 for sdm, and 1.89 for wdm. All estimates, except hospitalizations, were significant. The unmatched outcomes for the same outcomes were 3.36, -0.17, 3.80, 1.66, and 1.48 respectively.

Conclusions: The results of the study suggest that low-income families can benefit from the intervention by significantly reducing emergency department visits, asthma symptom days, and missed school and work days.

Implications for Policy, Delivery, or Practice: Asthma interventions that include a home environmental assessment and assistance with remediation of in-door asthma triggers in combination with asthma counseling can be very effective, especially for low-income, inner-city families. Insurance organizations should develop policies to reimburse the cost of these interventions.

Racial Disparities in Physical and Mental Health-Related Quality of Life among Medicare Managed Care Cancer Patients

Chintan Pandya, University of Rochester Medical Center; Yue Li, PhD, Department of Public Health Sciences, University of Rochester Medical Center; Chunkit Fung, MD MSCE, James P. Wilmot Cancer Center, University of Rochester Medical Center; Supriya Mohile, MD MPH, James P. Wilmot Cancer Center, University of Rochester Medical Center

Presenter: Chintan Pandya, MD MPH, Graduate Student, Department of Public Health Sciences, University of Rochester Medical Center, chintan_pandya@urmc.rochester.edu

Research Objective: Over 50 percent of newly diagnosed malignancies are found in people aged 65 years and older and over 60 percent of the cancer survivors are in this age range. Under-representation of older and minority patients in cancer clinical trials have resulted in disparities in their treatment and outcomes. The study aims to examine racial differences in health-related quality of life (HRQOL) outcomes and assess the association of sociodemographic, cancer-specific and general health characteristics with these outcomes among Black and White Medicare managed care patients diagnosed with cancer.
**Study Design:** We used the Surveillance, Epidemiology, and End Results-Medicare Health Outcomes Survey (SEER-MHOS) linkage population-based database developed by National Cancer Institute (NCI) and Center for Medicare & Medicaid Services (CMS) collaboration for this analysis. The MHOS assesses measures of HRQOL through SF-36, a valid and reliable instrument, which has eight scales representing separate constructs of HRQOL. The physical component summary (PCS) score of SF-36 incorporates physical functioning, role limitation-physical, bodily pain, and the general health scales and mental component summary (MCS) score of SF-36 includes the mental health, role limitation-emotional, social functioning, and vitality scales. Difference in median PCS and MCS scores (range from 0-100) among Black and White patients were tested using Wilcoxon rank-sum test. Multivariable linear regression analysis was performed to assess the association between race and HRQOL after controlling for socio-demographic variables including age, gender, marital status, education, and income; cancer-specific variables including time since diagnosis, stage of cancer, and treatment; and general health related variables including non-cancer comorbidities, depression and activities of daily living (ADL) deficits.

**Population Studied:** We conduct cross-sectional analysis on 13,091 (9.1% Black vs. 90.9% White) 65 years or older patients diagnosed with breast, colorectal or prostate cancer included in 8 MHOS cohorts (1998-2007). The first available survey after cancer diagnosis was used.

**Principal Findings:** The median PCS and MCS scores for all cancer patients were 39 and 54 respectively. Black cancer patients had lower median PCS (36.7 vs. 38.9, p<0.001) and MCS (48.7 vs. 51.3, p<0.001) scores compared to their White counterparts. After controlling for socio-demographic, cancer-specific and general health variables, PCS scores were lower (least-square mean: 38 vs. 40; p=0.003) for Black compared to White patients; MCS scores were not statistically different between the two racial groups. The interaction term between race and non-cancer comorbidities categories was significant (F-ratio=3.09, p=0.04). Factors associated with lower PCS scores include being female, older age, lower household income, lower education, advanced cancer stage, recent cancer diagnosis, having comorbidities, depressed and having ADL deficits (all p<0.05).

Similarly, factors associated with lower MCS scores include older age, low income, lower education, depressed and having ADL deficits (all p<0.05).

**Conclusions:** Overall HRQOL for older Medicare cancer patients is very low in this study population. PCS scores are lower for Black compared to White patients. The racial disparities in HRQOL are likely to be moderated by number of non-cancer comorbidities present.

**Implications for Policy, Delivery, or Practice:** The SEER-MHOS data suggest worse HRQOL for Black compared to White cancer patients among Medicare managed care beneficiaries that require targeted action plan by health care delivery system.

**Risky Business: Understanding the Role of Health Behaviors, Race and Insurance on Human Papilloma Virus Initiation and Completion in U.S. Women Aged 18-26**

Susanne Schmidt, University of Texas Health Science Center at San Antonio; Helen Parsons, University of Texas Health Science Center at San Antonio

**Presenter:** Helen Parsons, Ph.D., M.P.H., Assistant Professor, University of Texas Health Science Center at San Antonio, parsonsh@uthscsa.edu

**Research Objective:** To investigate disparities in Human Papilloma Virus (HPV) vaccination initiation and completion among young U.S. women, estimating time trends and variation in vaccination as well as identifying reasons why young females forgo vaccination.

**Study Design:** We used the 2008-2011 National Health Interview Survey (NHIS). Logistic regression models adjusted for survey design were computed to estimate the effect of demographic, socioeconomic, health status and behavior, and other vaccination behavior characteristics on HPV initiation (i.e., >=1 dose) and completion (i.e. >=3 doses). Logistic regression was also used to investigate factors significantly associated with choosing to forgo vaccination.

**Population Studied:** Females aged 18 to 26 (n=7,957) who participated in the 2008-2011 NHIS. A subsample of females who chose to forgo the vaccine (n=1,770) in 2008 and 2010 was also analyzed.
**Principal Findings:** HPV vaccination increased significantly among young women from 2008 to 2011. Vaccine initiation increased from 11.3% to 27.7% of young women, while vaccine completion increased from 5.9% to 14.9% over the study period. Multivariate regression demonstrated that women who were insured, had more than a High School education, exhibited moderate to heavy alcohol consumption, and those who participated in other health-seeking behavior (e.g., doctor visit in last 12 months, had flu shot in past year) had higher odds of both initiating and completing HPV vaccination (p<0.05 for all). Interestingly, neither poverty status nor financial hardships (defined as having delayed or forgone medical care because of associated costs) were significantly associated with vaccination. While we identified no significant association between race/ethnicity and vaccination initiation, Non-Hispanic blacks (OR[95% CI]: 0.48[0.35-0.66]) and Hispanics (OR[95% CI]: 0.75[0.57-0.99]) were both less likely to complete vaccination than non-Hispanic Whites respectively. Among women who chose to forgo vaccination, the most common reasons women identified included not needing vaccine (38.3%), not knowing enough about the vaccine (14.5%), and concern about the safety of the vaccine (12.5%). Further, among the non-vaccinated, multivariate regression demonstrated that minorities were more likely to identify lack of knowledge as the main reason for non-vaccination compared to non-Hispanic Whites.

**Conclusions:** While HPV vaccination rates are increasing for 18-26 year old women, vaccination rates are still low. Factors including minority status, insurance and health behaviors continue to play an important role in both vaccination uptake and completion. Additionally, minorities are more likely to state that they do not know enough about the HPV vaccine, which may contribute to their lower levels of vaccine completion.

**Implications for Policy, Delivery, or Practice:** Our research contributes to knowledge of the determinants and continued disparities in HPV vaccination in young women. Future implementation research should focus on improving vaccination among high-risk subgroups, particularly among the uninsured, minorities and those with high-risk behaviors. Specifically, the role of educational strategies in minorities and the role of insurance as the Affordable Care Act is implemented should be evaluated for determining best-practices to reduce disparities, improving overall vaccination rates in the population.

**The Role of Neighborhood Socioeconomic Status in Racial/Ethnic Disparities in Type 2 Diabetes**
Rebecca Piccolo, New England Research Institutes; Andre Araujo, New England Research Institutes; John McKinlay, New England Research Institutes

**Presenter:** Rebecca Piccolo, Sc.M., Project Manager/Biostatistician, Health Services and Disparities Research, New England Research Institutes, rpiccolo@neriscience.com

**Research Objective:** Racial/ethnic disparities in type 2 diabetes (T2D) are a major public health problem in the US, with African Americans (AA) and Hispanic Americans (HA) at a greater risk relative to Caucasians (CA). The search for contributors to disparities in T2D tends to focus on three major areas of research: (1) lifestyle and behavioral risk factors, (2) early biochemical changes, and (3) genetics. We hypothesize two additional, complementary contributors to racial/ethnic disparities: (4) individual and (5) neighborhood level socioeconomic factors.

**Study Design:** Participants were drawn from the Boston Area Community Health (BACH) Survey, a racially/ethnically diverse, (AA: 866; HA: 871; CA: 995) longitudinal cohort study of community-dwelling residents of Boston. Participants’ residential addresses were geocoded and merged with neighborhood-level data obtained from the US Census. Within this cohort, we identified 2,732 subjects without diabetes at baseline who were followed for diabetes incidence. The in-person interview included validated questionnaires on demographics, health care access/utilization, lifestyles, health status and behaviors, physical measures, and biochemical parameters.

**Population Studied:** The BACH Survey is a racially/ethnically diverse, prospective, longitudinal cohort study of Boston Massachusetts residents aged 30-79 at baseline. Non-diabetic participants (n=2,732) were followed for an average of 7.2 years for T2D incidence.

**Principal Findings:** In age-, gender-, and BMI-adjusted models, black and Hispanic participants were twice as likely to develop T2D over the 7.2 year study period (AA: OR=2.27,
adjusting for known risk factors including socioeconomic status (SES), suggesting that genetic factors may explain some of this population difference in risk. However, recent genetic studies examining the association of genetic ancestry (as measured by Ancestry Informative Markers (AIMs)) and T2D have been inconclusive with results of genetic ancestry being attenuated, or completely eliminated, when adjusting for SES. Therefore, the Boston Area Community Health (BACH) Survey performed an admixture analysis in a racially/ethnically diverse population in order to determine the association between genetic ancestry, socioeconomic factors, and incident T2D.

**Study Design:** The BACH Survey is a racially/ethnically diverse, (AA: 866; HA: 871; CA: 995) longitudinal cohort study of men and women from Boston, Massachusetts. Participants aged 30-79 at baseline (2002-2005) were followed approximately 5- (2006-2010) and 7- (2010-2012) years later. A panel of 63 AIMs designed to discriminate percent African, Native American, and European ancestry were collected from 2,732 non-diabetic participants, along with a breadth of measures including: sociodemographics, health care access/utilization, lifestyle/behavior, health status, physical measures, and biochemical parameters.

**Population Studied:** The BACH Survey is a racially/ethnically diverse, prospective, longitudinal cohort study of Boston Massachusetts residents aged 30-79 at baseline. Non-diabetic participants (n=2,732) were followed for an average of 7.2 years for T2D incidence.

**Principal Findings:** We examined the relationship between % African and % Native American ancestry on incident T2D. In age- and gender-adjusted models, the odds of developing T2D were 14% higher (Odds Ratio (OR)= 1.14, 95% CI [1.07-1.22]) for every 10% increase in African ancestry, relative to European ancestry. Results were similar for Native American ancestry although not statistically significant (OR=1.14 [0.97-1.33]). As in previous studies, these results were attenuated with further adjustment for socioeconomic factors (African ancestry: OR=1.07, [0.99-1.15]; Native American ancestry: OR=0.99, [0.83-1.18]). Further, genetic ancestry only accounted for 0.3% of the variation in T2D incidence (by comparison, income, education, and occupation combined accounted for 1.4% and body mass index 1.6%).
Conclusions: We conclude that while African and Native American genetic ancestry are associated with incidence of T2D in minimally adjusted models, the effect of genetic ancestry on T2D is likely explained by differences in socioeconomic factors.

Implications for Policy, Delivery, or Practice: Genetic ancestry appears to have little association with T2D beyond its association with socioeconomic factors. Furthermore, genetic studies have failed to identify genes that can explain a large portion of the observed population difference in risk of T2D. It is likely that non-genetic factors, namely socioeconomic factors, lead to the observed racial/ethnic disparities in T2D incidence.

Are There Racial Disparities in Psychotropic Drug Use and Expenditures in a Nationally Representative Sample of Men in the United States? Evidence from the Medical Expenditure Panel Survey

Geraldine Pierre, Johns Hopkins Bloomberg School of Public Health; Roland J. Thorpe Jr., Department of Health Policy and Management, Hopkins Center for Health Disparities Solutions, Johns Hopkins Bloomberg School of Public Health; Gniesha Y. Dinwiddie, African American Studies Department, University of Maryland; Darrell J. Gaskin, Department of Health Policy and Management, Hopkins Center for Health Disparities Solutions, Johns Hopkins Bloomberg School of Public Health

Presenter: Geraldine Pierre, MSPH, PhD Candidate, Department of Health Policy and Management, Hopkins Center for Health Disparities Solutions, Johns Hopkins Bloomberg School of Public Health, gpierre@jhsph.edu

Research Objective: To determine whether racial disparities exist in psychotropic drug use and expenditures in a nationally representative sample of men 18-64 who access the health care system in the United States.

Study Design: We employed a pooled cross-sectional design for this study and used a two-part probit-GLM model for analyses. First, a probit model was run to determine the likelihood of drug use by race. Second, generalized linear modeling (GLM) assessed differences in expenditures, by race, among individuals who reported use of one or more psychotropic drugs.

Population Studied: Data was extracted from the 2000-2009 Medical Expenditure Panel Survey (MEPS), a longitudinal survey that covers the U.S. civilian non-institutionalized population. Full Year Consolidated, Medical Conditions, and Prescribed Medicines data files were merged across 10 years of pooled data. Only individuals who were interviewed across all three components were included in the final analyses. The sample of interest was limited to adult males 18-64, who reported their race as White, Black, Hispanic, or Asian. Appropriate survey weighting techniques were applied according to MEPS documentation.

Principal Findings: We found minority men had a lower probability of psychotropic drug use (Black = -4.3%, 95% Confidence Interval [CI] = -5.5, -3.0; Hispanic = -3.8%, 95% CI = -5.1, -2.6; Asian = -4.5%, 95% CI = -6.2, -2.7) compared to White men. While average spending varied by race (White: $664.59, Black: $990.87, Hispanic: $725.80, Asian: $932.96), after controlling for demographic and health status variables, there were no statistically significant race differences in expenditures.

Conclusions: This paper reveals that racial and ethnic disparities exist in the use of psychotropic drugs for men, presenting problems of access to mental health care and services.

Implications for Policy, Delivery, or Practice: Implications of our findings suggest public health interventions must ensure equitable access to psychotropic drugs for men. Practical solutions to addressing this access problem include greater community outreach and cultural sensitivity training for practitioners. Policymakers also play a role in passing and enforcing legislation that promotes safe and necessary psychotropic drug access.

Do Discontented Physicians Provide Poorer Quality Medical Care?

David Pober, New England Research Institutes; Felicia L Trachtenberg, New England Research Institutes; Lisa D Marceau, New England Research Institutes; John B McKinlay, New England Research Institutes

Presenter: David Pober, Ph.D., Senior Research Scientist / Biostatistician, New England Research Institutes, dpober@neriscience.com
Research Objective: Surveys of primary care physicians report alarming levels of dissatisfaction within the evolving medical workplace. Reports suggest physician discontent adversely affects the content and quality of medical care, and possibly patient outcomes. We examine the relationship between physician discontent and clinical decision making for two commonly encountered pain conditions.

Study Design: A balanced factorial experiment was conducted with primary care physicians who viewed two clinically authentic videos of “patients” with symptoms suggesting either undiagnosed sciatica, or diagnosed symptomatic knee osteoarthritis (OA). Half of the patients with sciatic symptoms assertively requested oxycodone, while half of those with OA requested Celebrex. The other half of each cohort simply requested pain relief. The “patients” were professional actors, differing by gender, race/ethnicity and socioeconomic status. The well-validated Physician Worklife Survey (Williams et al., 1999) was employed to measure physician discontent. We differentiated actions any physician should or should not take when encountering the two conditions. Physician actions were modeled as a function of physician discontent using logistic regression models controlled for all patient and physician design factors, as well as any significant interactions between physician discontent and the style of the patient request.

Population Studied: 192 eligible physicians, stratified by years of clinical experience and gender, were recruited to participate.

Principal Findings: Results were generally consistent across the two scenarios. Regarding actions physicians “should” take (e.g. prescribe non-COX-2 NSAIDs, provide advice on health behaviors) there were no significant main effects of physician discontent on these outcomes. However, there were interactive effects such that assertive patients received more advice about ergonomics (Odds Ratio (OR) = 2.88, p = 0.04 for the interaction) and more advice about changing exercise habits (OR = 2.24, p = 0.05) with increasing physician discontent. OA patients assertively requesting medication received more advice about structured physical therapy and stretching (Odds Ratio (OR) = 6.54, p = 0.007) with increasing physician discontent. Among actions that physicians “should not” take, the probability of ordering an MRI in sciatica cases with assertive requests was lower with increasing physician discontent (OR = 0.44, p = 0.08), while OA cases exhibited a simple main effect of physician discontent with increasing probability of having an MRI ordered (OR = 1.66, p = 0.08). In sciatica cases, the probability of being prescribed narcotic analgesics increased with physician discontent (OR = 1.48, p = 0.04).

Conclusions: Physician discontent appears to result in some significantly different clinical decisions for “patients” with symptoms of two common conditions. There is noteworthy consistency across the two scenarios. Physicians prescribed appropriate NSAIDs equivalently, regardless of discontent. However, discontented physicians may not wish to take the time to offer advice, and may somewhat dismissively prescribe narcotic analgesics and order MRIs inappropriately.

Implications for Policy, Delivery, or Practice: Consistent with related research, we find patient assertiveness appears to modify usual patterns of clinical decision making. More assertive patients may receive improved medical care, reducing healthcare disparities associated with physician discontent.

Changes in Patient Activation and Self-Management: Are There Racial and Ethnic Disparities?

Javiera Pumarino, Northwestern University; Raymond H. Kang, Northwestern University; Megan C. McHugh, Northwestern University

Presenter: Javiera Pumarino, B.A., Research Assistant, Feinberg School of Medicine, Center for Healthcare Studies, Northwestern University, j-pumarino@northwestern.edu

Research Objective: Chronically ill patients are frequently expected to make behavioral changes in order to improve their health status and quality of life. Highly activated patients—or those who have the ability and disposition to manage their health—are more likely to engage in self-management behaviors. Thus, successful management of a chronic condition is intimately related to high levels of patient activation. Race and ethnicity have been widely recognized as drivers of health care disparities. Relative to whites, racial and ethnic minorities have lower levels of activation, higher prevalence of chronic conditions, and poor self-management.

Our objective was to assess whether changes in patient activation were associated with changes...
in self-management behaviors for chronically ill patients, and to explore the influence of patients’ race and ethnicity on this association.

**Study Design:** We used panel data from two rounds (2007-2008 and 2011-2012) of the Aligning Forces for Quality Consumer Survey. The first round was a random digit dial telephone survey of adults (18 years or older) with at least one chronic condition. The response rate was 48%. The second round had a retention rate of 60%.

Patient activation was measured using the 13-item Patient Activation Measure. Self-management behaviors were assessed through questions about patients’ diet and exercise. Race (African American or white), ethnicity (Hispanic), sex, age, number of chronic conditions, insurance status, education level, and usual source of care were included in the models as control variables.

All health behavior measures were analyzed using a random-effects (RE) logistic. Interaction terms for Black race and Hispanic ethnicity with patient activation were also included.

**Population Studied:** 4,792 individuals completed both rounds of the survey. 24% self-identified as African American, 6% as Hispanic, and 66% as Caucasian. All participants reported having at least one of the following chronic conditions: diabetes, hypertension, heart disease, asthma, or depression.

**Principal Findings:** Increases in patient activation were associated with positive changes on all self-management behaviors (p<0.001).

Analyzing the interaction terms for Black race and Hispanic ethnicity with patient activation, we found that, relative to whites, changes in patient activation had a weaker association with self-management for Hispanics (eating 5 servings of fruits and vegetables most days of the week OR=0.98, p<0.05) and for African Americans (maintaining low fat diet OR=0.99, p<0.05; exercising on a regular basis OR=0.99, p<0.05).

**Conclusions:** Our findings suggest that, for the chronically ill, improved patient activation has a positive effect on self-management behaviors. However, patient activation has a lower effect on improving self-management behaviors for racial and ethnic minorities.

**Implications for Policy, Delivery, or Practice:** Interventions aimed at improving the health of chronically ill patients should include efforts to increase patient activation. However, this may not be enough to successfully improve the self-management behavior of racial and ethnic minority patients. Future research should focus on components that may complement interventions based on patient activation.

**Does Dual-Eligibility Affect Post-Acute Nursing Home Care Outcomes?**

Momotazur Rahman, Brown University; Kali Thomas, Brown University; Denise Tyler, Brown University; David C Grabowski, Harvard University; Vincent Mor, Brown University

**Presenter:** Momotazur Rahman, Ph.D., Investigator, Community Health, Brown University, momotazur_rahman@brown.edu

**Research Objective:** Dual-eligibles (Medicaid-eligible Medicare beneficiaries) are a particularly vulnerable group: they tend to be poor, report lower health status and utilize more health care services than other beneficiaries. This paper has two goals. The first is to examine whether dual eligibility affects health and utilization outcomes following skilled nursing facility admission. The second is to examine whether such dual-non-dual differences in outcomes are associated with state policies regarding long-term care.

**Study Design:** We used four outcome measures: becoming a long-stay resident (i.e. stayed more than 100 days following nursing home admission), discharge to home within 30 days of nursing home admission without any adverse event like hospitalization or death in following 30 days, 30-day re-hospitalization and 180 day mortality. We estimated dual-non-dual difference in outcomes controlling for patients’ clinical and neighborhood characteristics and nursing home fixed effects among groups patients with same primary diagnosis (hip fracture, heart failure and stroke) and similar Elix-Hauser co-morbidity index and. We also estimated such difference in outcome measure within groups of patients with same likelihood (propensity score) of being dually eligible. To examine the role of state policies, we estimated logit models with four different outcomes onto patients’ clinical and neighborhood characteristics, state fixed effects, and interactions of state variables with the dual-eligibility dummy variable. These interactions demonstrate how state policies affect the outcomes differently for the dual-eligibles compared to the non-duals.

**Population Studied:** 690,596 Medicare fee-for-service beneficiaries residing in the contiguous 48 states who had not had a previous nursing
home stay who were discharged to skilled nursing facility from a general hospital following acute stay between July 2004 and June 2005. **Principal Findings:** Dually eligible individuals comprised 22.2% of our cohort. Duals were two times more likely to become long-stay nursing home residents than the non-duals and there was no significant difference in re-hospitalization and mortality. These findings are very robust to alternative sample or method specification. Higher Medicaid reimbursement rates were associated with increased difference in length-of-stay between duals and non-duals and higher assisted living penetration in states was found to increase such differences in terms of re-hospitalization and mortality. Compared to the rest, the four states that pay SNF copayments for duals have smaller dual-non-dual difference in length of stay. **Conclusions:** Health conditions, residential neighborhood characteristics and treating nursing facility explained most of the observed difference in mortality and re-hospitalization, but only a very small fraction of the observed difference in likelihood of becoming a long-stay resident. **Implications for Policy, Delivery, or Practice:** Duals are being kept at nursing for relatively longer time because they have lower incentives (no cost sharing, poor quality home) to go back to community. This suggests that these patients could have been discharged from the SNFs quickly and kept in relatively less expensive settings without increasing health risk. Assisted living has the potential to serve as a cost-effective substitute for higher-intensity nursing home care for some people. Higher Medicaid payment rates potentially provide additional incentive to keep the dual-eligibles in the nursing home for longer periods of time. **Funding Source(s):** NIH  **Poster Session and Number:** A, #273  

**Tackling Disparities with the Patient-Centered Medical Home: A Mixed Methods Study**  
Nadine Reibling, Harvard School of Public Health; Meredith Rosenthal, Harvard School of Public Health

Poster: Nadine Reibling, Harkness Fellow in Healthcare Policy and Practice, Health Policy and Management, Harvard School of Public Health, nreiblin@hsph.harvard.edu

**Research Objective:** Persistent disparities in health and healthcare utilization are identified as one of the big challenges of healthcare policy. A strong primary care system is often put forward as a remedy for disparities in the receipt of healthcare services. Thus recent initiatives promoting the patient-centered medical home (PCMH) promise to enhance equity in healthcare utilization. The aim of this study is to find out if patient-centered medical homes have the potential to reduce racial/ethnic and socioeconomic disparities in healthcare services. Moreover, we investigate the role disparities play in existing medical home pilots and how this might affect outcomes.  

**Study Design:** The study uses a mixed methods design. A quantitative analysis based on the 2010 Medical Expenditure Panel Survey investigates to what extent having a medical home reduces disparities in preventive care use between racial/ethnic and socioeconomic groups. The second part of the study includes an extended document analysis and 30 qualitative interviews with key actors in five medical home initiatives (Colorado, Massachusetts, Pennsylvania, Rhode Island, and New Orleans).  

**Population Studied:** The quantitative analysis covers a nationally representative sample of civilian, non-institutionalized persons in the United States. The medical home initiatives studied cover pilots in different parts of the country which vary on a number of crucial characteristics (start date, number of practices included, physician payment, size of the minority population, policy process/initiation).  

**Principal Findings:** In line with earlier research, the study finds that medical homes have the potential to improve quality of care. Having a medical home also reduces socioeconomic disparities in care utilization but this effect is mainly based on persons having a usual care provider. Although mostly motivated by cost and quality considerations, existing medical home pilots often focus on providers of vulnerable populations such as Community Health Centers. By increasing resources and quality for those providers, existing between-provider disparities might be reduced. On the other hand, Community Health Centers seem to struggle more with the implementation of PCMH principles so that disparities might increase; at least temporarily. The low priority given to disparities compared to quality and cost outcomes might undermine the potential of
We used logistic regression to evaluate the claims data from California's Medicaid program. The study examined 12 months of administrative data among HIV-positive beneficiaries. This study examines whether disparities in receipt of CD4 monitoring are likely to adhere to treatment guidelines. The analysis was conditional on continuous enrollment and at least one outpatient healthcare encounter during the 12-month study period.

**Research Objective:** CD4 tests are an essential service for people with Human Immunodeficiency Virus (HIV). Treatment decisions related to lifesaving antiretroviral (ARV) medications are contingent on CD4 cell count. Patients who do not receive recommended CD4 monitoring are unlikely to receive ARVs when indicated. This study examines whether disparities in receipt of CD4 tests exist among HIV-positive Medicaid beneficiaries.

**Study Design:** This retrospective observational study examined 12 months of administrative claims data from California's Medicaid program. We used logistic regression to evaluate the association of patient demographics (age, gender, race/ethnicity, and language), mental health status, use of ARV medications, and provider volume with receipt of at least one CD4 test over a 12 month period from March 2008 through February 2009.

**Population Studied:** The study population included 3,310 HIV-positive Medicaid beneficiaries in Southern California. The analysis was conditional on continuous enrollment and at least one outpatient healthcare encounter during the 12-month study period.

**Principal Findings:** Descriptive analysis showed that only 64% of the study population received any CD4 test during the study year despite having continuous enrollment in coverage and at least one outpatient medical encounter. Appropriate (at least once per year) CD4 testing was significantly associated with being younger, white, speaking English as primary language, a history of mental illness or substance abuse, using ARV medications, and having a primary treating provider more experienced with HIV patients.

**Conclusions:** Substantial disparities in receipt of CD4 tests between racial/ethnic, age and language groups indicate differential treatment that may result from cultural norms, self-efficacy, perceived stigma, knowledge of clinical guidelines, or provider discrimination. The association of CD4 screening with provider experience or volume suggests that providers with fewer HIV-positive patients may be less likely to adhere to treatment guidelines.

**Implications for Policy, Delivery, or Practice:** Because ARV treatment is predicated on CD4 cell count, identification of disparities in receipt of CD4 testing elucidates one important potential pathway for previously reported disparities in ARV treatment, which may be susceptible to intervention at the provider and patient level. Further research is needed to better understand the specific factors driving observed disparities and potential mechanisms to improve equity of care for HIV-positive Medicaid beneficiaries.

Disparities in CD4 Monitoring among HIV-Positive Medi-Cal Beneficiaries: Evidence of Differential Treatment at the Point of Care

Dylan Roby, University of California at Los Angeles, Fielding School of Public Health; Greg Watson, University of California at Los Angeles, Center for Health Policy Research; Anna Davis, University of California at Los Angeles, Fielding School of Public Health

**Research Objective:** CD4 tests are an essential service for people with Human Immunodeficiency Virus (HIV). Treatment decisions related to lifesaving antiretroviral (ARV) medications are contingent on CD4 cell count. Patients who do not receive recommended CD4 monitoring are unlikely to receive ARVs when indicated. This study examines whether disparities in receipt of CD4 tests exist among HIV-positive Medicaid beneficiaries.

**Study Design:** This retrospective observational study examined 12 months of administrative claims data from California’s Medicaid program. We used logistic regression to evaluate the association of patient demographics (age, gender, race/ethnicity, and language), mental health status, use of ARV medications, and provider volume with receipt of at least one CD4 test over a 12 month period from March 2008 through February 2009.

**Population Studied:** The study population included 3,310 HIV-positive Medicaid beneficiaries in Southern California. The analysis was conditional on continuous enrollment and at least one outpatient healthcare encounter during the 12-month study period.

**Principal Findings:** Descriptive analysis showed that only 64% of the study population received any CD4 test during the study year despite having continuous enrollment in coverage and at least one outpatient medical encounter. Appropriate (at least once per year) CD4 testing was significantly associated with being younger, white, speaking English as primary language, a history of mental illness or substance abuse, using ARV medications, and having a primary treating provider more experienced with HIV patients.

**Conclusions:** Substantial disparities in receipt of CD4 tests between racial/ethnic, age and language groups indicate differential treatment that may result from cultural norms, self-efficacy, perceived stigma, knowledge of clinical guidelines, or provider discrimination. The association of CD4 screening with provider experience or volume suggests that providers with fewer HIV-positive patients may be less likely to adhere to treatment guidelines.

**Implications for Policy, Delivery, or Practice:** Because ARV treatment is predicated on CD4 cell count, identification of disparities in receipt of CD4 testing elucidates one important potential pathway for previously reported disparities in ARV treatment, which may be susceptible to intervention at the provider and patient level. Further research is needed to better understand the specific factors driving observed disparities and potential mechanisms to improve equity of care for HIV-positive Medicaid beneficiaries.

Comparing AHRQ Maternal Quality and Safety Indicators for Asian and Pacific Islander Subgroups in Hawaii

Tetine Sentell, University of Hawaii at Manoa; Hyeong Jun Ahn, Biostatistics Core, University
Hospitalizations for this indicator were significantly across racial/ethnic groups. From Cesarean delivery, which did not vary
safety indicators except for obstetric trauma rate
significant differences were seen across
Principal Findings: In unadjusted analyses,
significant differences were seen across racial/ethnic groups for all maternal quality and safety indicators except for obstetric trauma rate from Cesarean delivery, which did not vary significantly across racial/ethnic groups. (Hospitalizations for this indicator were extremely low (less than 10 total) across all groups and were not considered in further analyses). Differences were seen specifically between Asian and Pacific Islander subgroups. For instance, Chinese had the lowest unadjusted percentage (23.95) of Cesarean deliveries, while Filipino women had the highest percentage (29.11). Chinese (7.69) and Japanese (5.65) had high percentage of obstetric trauma from vaginal deliveries with instruments while Hawaiians had the lowest percentages (2.07).

Significant differences by race/ethnicity overall and among Asian and Pacific Islander subgroups specifically remained in multivariable models. In particular, both Chinese (RR: 1.84; CI: 1.45-2.27) and Japanese (RR: 1.31; CI: 1.12-1.54) retained higher rates of obstetric trauma for vaginal deliveries compared to Whites, while Native Hawaiians (RR: 0.57; CI: 0.48-0.67) had significantly lower rates and other racial/ethnic comparisons were not significantly different. Similarly, Filipino (RR: 1.11; 95% CI: 1.06-1.16) and other Pacific Islander women (RR: 1.20; CI: 1.13-1.27) had significantly higher rates of Cesarean deliveries compared to White women, while other racial/ethnic groups did not differ significantly.

Conclusions: Significant variation was seen for Asian and Pacific Islander subgroups across AHRQ maternal quality and safety indicators. Notably, high rates of obstetric trauma were seen among Chinese and Japanese women with vaginal deliveries and high rates of Cesarean deliveries were seen among Filipino and other Pacific Islander women.

Implications for Policy, Delivery, or Practice: Asian and Pacific Islanders subgroups must be disaggregated to understand patterns, to identify possible disparities, and to design effective interventions. This is particularly important to consider in childbirth, which is the most common reason for hospital admission among women.

The Promotora Explained Everything:
Participant Experiences During a Household-Level Diabetes Education Program for Rural Hispanics Living in Washington State
Megan Shepherd-Banigan, University of Washington; Sarah Hohl, Fred Hutchinson Cancer Reserach Center; Catalina Vaughn, Fred Hutchinson Cancer Reserach Center; Beti Thompson, Fred Hutchinson Cancer Reserach Center
**Presenter:** Megan Shepherd-Banigan, MPH, Student, Health Services, University of Washington, msb23@uw.edu

**Research Objective:** In the United States Hispanics, particularly those living in rural areas, are at higher risk for diabetes than non-Hispanic whites. There is a need to design and evaluate community-based, culturally-relevant interventions targeting diabetes education, prevention and self-management for this vulnerable population. This study describes participant experiences of a household-level, community health worker-led intervention to increase social support, behavioral skills, and self-efficacy in an effort to improve diabetes-related health behaviors and outcomes.

**Study Design:** The Home Health Party (HHP) intervention, a component of the Hispanic Diabetes Education and Prevention Project, employed constructs of the Social Cognitive Theory and used trained promotores (community health workers) to deliver a series of household-level education sessions and distribute incentives to support diabetes-related behavior change. Forty open-ended, structured interviews were administered to a randomly selected sample of 430 intervention participants. Qualitative methods were used to code and analyze the interview transcripts.

**Population Studied:** Diabetic and pre-diabetic Hispanics living in a rural, agricultural area in Washington State.

**Principal Findings:** Four primary themes emerged from interviews: 1. participants desire for and the process of improving knowledge about diabetes; 2. experiences of building skills for diabetes management; 3. developing social support and 4. embracing change. Respondents viewed the HHPs as an opportunity to gain new knowledge about diabetes and diabetes management. Participants regarded the promotor as a credible role model who imparted advice, skills demonstrations, and social support to help them achieve positive lifestyle changes. Incentives, such as a Mexican cookbook and pedometer, provided instant gratification and motivation to achieve behavior change by allowing participants to tangibly gauge their progress. Almost all participants articulated at least one detail about specific behavior changes they had made, particularly in regards to diet and physical activity. Several participants reported positive impacts on family-level behaviors, generally in the area of improved nutrition. Further, respondents reported reduced HbA1C levels, weight loss, and a general sense of improved well-being.

**Conclusions:** This intervention is a promising, culturally and linguistically relevant strategy for addressing diabetes among this underserved, vulnerable population and this study suggests how the intervention and other similar programs might be strengthened to achieve greater impact.

**Implications for Policy, Delivery, or Practice:** Interventions that involve family members and aim to improve social support may be an effective strategy for improving health behaviors and chronic health outcomes among vulnerable Hispanic populations. Despite this, many behavior change interventions continue to target individuals. This intervention builds on theory-based behavior change approaches and extends the emphasis from the individual to the household. Our study highlights several important considerations regarding the design of diabetes management interventions for rural Hispanic populations. Promotores, trusted members of the community, are a critical component for any intervention as they provide social support and encourage behavior change by building relationships based on trust and cultural understanding. Well-designed tools that provide step by step examples of behaviors, such as cookbooks, and that aid participants to monitor behavior change and behavioral outcomes, such as pedometers and glucose monitors, serve to build skills and improve confidence to achieve behavior change goals. Finally, targeting households is a promising strategy for creating a supportive environment for individual and family lifestyle changes that benefit the entire family unit.

**Friends, Families, and Schools: What Matters Most in Latino Youth Violence?**

Rashmi Shetgiri, University of Texas Southwestern Medical Center and Children’s Medical Center; Hua Lin, PhD, University of Texas Southwestern Medical Center; Glenn Flores, MD, University of Texas Southwestern Medical Center and Children's Medical Center

**Presenter:** Rashmi Shetgiri, M.D., M.S.H.S., Assistant Professor of Pediatrics, Pediatrics, University of Texas Southwestern Medical Center and Children's Medical Center, rashmi.shetgiri@utsouthwestern.edu
Research Objective: Violence among adolescents is a significant public-health problem, and disproportionately affects Latinos. Little is known about contextual risk and protective factors for Latino youth violence. The study objective was to identify individual, family, peer, and school risk and protective factors that predict violence involvement among Latinos.

Study Design: The National Longitudinal Study of Adolescent Health is a longitudinal survey of a nationally representative sample of 7th-12th grade students, using a school-based clustered sampling design, and consisting of interviews with youth, parents, and school administrators. Predictors at Wave 1, and the outcome at Wave 2, were analyzed among Latinos. The outcome was child involvement in violence (physical fighting/weapon use/violent injury) in the past 12 months. A continuous violence-involvement scale was created using 8 items, and dichotomized at the 80th percentile. Bivariate and stepwise multivariable logistic regression analyses examined associations of individual, peer, family, and school characteristics with violence involvement among Latino adolescents.

Principal Findings: 25% of the 3,349 Latino adolescents in this sample were involved in violence. In bivariate analyses, male gender (79% vs. 58%), past violent victimization (34% vs. 13%), violence exposure (54% vs. 32%), smoking (58% vs. 40%), drug use (69% vs. 39%), emotional distress, peer delinquency, and low family and school connectedness were significantly (p-value less than .01) associated with higher likelihood of violence involvement. Violence involvement was 30% for those in the highest tertile on the emotional distress scale vs. 19% for the lowest tertile (p=.02), and 32% for those in the highest tertile on the peer delinquency scale vs. 14% for the lowest tertile (p=.01). Eighteen percent of adolescents in the highest tertile on the family connectedness scale were involved in violence vs. 34% in the lowest tertile (p=.01), and 14% of adolescents in the highest tertile on the school connectedness scale were involved in violence vs. 42% in the lowest tertile (p=.01). In multivariable analyses, male gender (OR, 3.2; 95% CI, 1.6-6.3), drug use (OR, 2.6; 95% CI, 1.3-5), past violent victimization (OR, 2.4; 95% CI, 1.5-3.8), and violence exposure (OR 1.9; 95% CI, 1.1-3.4) predicted violence involvement, whereas higher school connectedness (OR 0.5; 95% CI, 0.3-0.7) and increasing age (OR 0.7; 95% CI, 0.6-0.7) were protective. Peer and family factors were not associated with violence involvement.

Conclusions: One in four Latino youth is involved in violence. Male gender, drug use, past violent victimization, and violence exposure are important risk factors, and school connectedness and older age may be protective. Peer and family factors are not associated with violence involvement, after adjusting for individual and school factors.

Implications for Policy, Delivery, or Practice: The study findings suggest that interventions to reduce Latino youth violence may need to address drug use and victimization from and exposure to violence. Enhancing school connectedness may prove to be a particularly effective violence prevention-strategy for Latino youth.

Patient Responses to a Brief Patient Health Assessment: Is Non-Response a Clinical Concern?
Stephanie Shimada, Bedford VA Medical Center; Julie E. Volkman, PhD, eHealth Quality Enhancement Research Initiative, Dept of Veterans’ Affairs; Thomas K. Houston, MD MPH, eHealth Quality Enhancement Research Initiative, Dept of Veterans’ Affairs; Hector P. Rodriguez, PhD, UCLA Fielding School of Public Health; Alex H. Krist, MD MPH, Virginia Commonwealth University; Rodger S. Kessler, PhD, University of Vermont College of Medicine; Russell E. Glasgow, PhD, National Cancer Institute

Presenter: Stephanie Shimada, Ph.D., Research Health Scientist, Center for Health Quality, Outcomes, and Economic Research, Bedford VA Medical Center, stephanie.shimada@va.gov

Research Objective: Routine collection of patient-reported data to assess patient behavioral risk factors has the potential to assist patients and their providers with improved health management. Patient responses can help flag problem behaviors and alert clinicians to the need for further psychological screening. Non-response to all or specific items is potentially problematic in that it may prevent an existing problem from being addressed – especially if
that non-response has the potential to widen disparities in the quality of care.

**Study Design:** A brief patient health assessment covering behavioral health domains relevant to primary care (diet, exercise, stress, mood, sleep apnea, tobacco, alcohol, and drug use) and patient demographic data was piloted with patients in 9 primary care practices (N=463). Data from the returned health assessments was analyzed with univariate and bivariate statistics and logistic regression to determine demographic characteristics associated with complete (all items answered) versus incomplete (some items left missing) health assessments.

**Population Studied:** Patients arriving for non-urgent primary care visits at one of nine primary care practices during the 1-3 week pilot implementation period were invited to participate. The practices included 4 federally-qualified health centers (FQHCs) in California, 4 primary care practices affiliated with practice-based research networks (PBRNs) in Vermont and Virginia, and a primary care clinic at a Veterans' hospital in Massachusetts.

**Principal Findings:** Overall, forty-six percent of health assessments were missing responses to one or more items, ranging from 28.5% incomplete at the FQHCs to 84.4% at the PBRNs. Health assessments with all items complete had a higher number of positive screens than those which were incomplete (4.1 vs 3.4 positive screens, respectively). Rates of non-response for individual items ranged from 0.22% for frequency of consuming fast food meals or snacks to 19.22% for minutes of exercise in the past week and 25.7% for frequency of illegal drug or prescription medication use. Younger age, not having completed high school, foreign birth, Hispanic/Latino origin, and membership in a non-African-American minority group were all significantly associated with completing all items. Being an African-American patient was associated with significantly lower odds of having completed all items. In a multivariable model race/ethnicity remained a significant predictor of completeness after adjusting for age, sex, education, and foreign birth.

**Conclusions:** Completeness of the health assessment varied significantly by site and was significantly associated with patient demographic characteristics. Cultural expectations surrounding clinicians’ authority, levels of trust in the medical profession, or the reluctance to answer certain types of questions in writing may be impacting patients’ willingness to complete all items.

**Implications for Policy, Delivery, or Practice:** Future research should correlate patient-reported responses on the health assessment with evidence on health behaviors in the medical record to improve our understanding of the meaning of non-response on items, and to discern whether certain groups are more susceptible to social desirability bias. Providers reviewing self-reported health assessments with patients may want to verbally inquire about incomplete items to ensure that incompleteness does not result in failure to target harmful health behaviors.

**Disparities in the Quality of Adjuvant Treatment for Breast Cancer**

Melony Sorbero, RAND; Andrew W. Dick, RAND Corporation; Ann C. Haas, RAND Corporation; Ann S. Hamilton, University of Southern California; Kendra L. Schwartz, Wayne State University; Jennifer J. Griggs, University of Michigan

**Presenter:** Melony Sorbero, Ph.D., M.P.H., M.S., Policy Researcher, RAND, melony_sorbero@rand.org

**Research Objective:** Black women and women of lower socio-economic status (SES) experience worse breast cancer outcomes than white women, and the differences are not fully accounted for by differences in stage at presentation and tumor biology. The objectives of this study were to assess whether the quality of care (guideline-concordant chemotherapy, radiation therapy, and endocrine therapy), differed by race and neighborhood SES, and whether those differences persisted after controlling for other patient characteristics and disease characteristics.

**Study Design:** Drawing from the universe of women diagnosed with breast cancer in two SEER registries, we selected a random sample stratified by race/ethnicity and vital status. Sampled women were invited by mail to participate in a retrospective study of breast cancer treatment patterns and outcomes. One registry required that family members of deceased women be approached for consent, while the other registry did not. Once consent was obtained, physicians involved in the women’s treatment were contacted to request
access to their medical records for abstraction by trained SEER staff. We abstracted data from surgical, radiation therapy, and oncology charts. We contacted primary care physicians for long-term follow-up information as necessary. Data collected included subject socio-demographic characteristics, type of insurance, tumor characteristics, treatment course, detailed radiation and chemotherapy dosing information, timing of treatments, breast cancer recurrences and vital status in 2012. We developed measures of the quality of adjuvant treatment, including the guideline-concordant receipt of chemotherapy, radiation therapy and endocrine therapy based on guidelines in place at the time of diagnosis. SES was assessed using a composite of 6 measures from the census data at the block group level. Weighted logistic regression models assessed differences in the receipt of guideline concordant chemotherapy, radiation therapy, and endocrine therapy by race/ethnicity and SES controlling for demographic characteristics, tumor characteristics, comorbidities, treatment site, and year of treatment.

**Population Studied:** Women diagnosed with breast cancer 1998-2004 who resided in the catchment area of two SEER registries at the time of their diagnosis.

**Principal Findings:** The analytic sample included 1936 women. Black women were less likely to receive guideline concordant radiation therapy (p=.02) and endocrine therapy (p=.01) than non-Hispanic white women. There were no significant differences in guideline concordant chemotherapy by race. Women in the bottom quartile of SES were less likely to receive guideline concordant endocrine therapy (p<.01) than women in the top quartile of SES, but there were no significant differences in the receipt of guideline concordant chemotherapy or radiation therapy. In multivariate analyses, women in the lowest SES quartile were less likely to receive guideline concordant endocrine therapy, but race was no longer significant. SES did not remain significant for the other measures of guideline concordant care. Type of insurance was associated with guideline concordant endocrine therapy.

**Conclusions:** Observed racial disparities in the receipt of guideline concordant care region specific and are mitigated when controlling for SES and type of insurance. Disparities in the receipt of guideline concordant adjuvant therapy may contribute to documented disparities in outcome.

**Implications for Policy, Delivery, or Practice:** Improved insurance coverage through ACA implementation may reduce regional variation and disparities in breast cancer quality of care.

**Disparities in Outcome Among Women with Breast Cancer: Are They Due to Disparities in Quality of Care?**

Melony Sorbero, RAND Corporation; Andrew W. Dick, RAND Corporation; Hao Yu, RAND Corporation; Ann C. Haas, RAND Corporation; Ann S. Hamilton, University of Southern California; Kendra L. Schwartz, Wayne State University; Jennifer J Griggs, University of Michigan

**Presenter:** Melony Sorbero, Ph.D., M.P.H., M.S., Policy Researcher, RAND Corporation, melony_sorbero@rand.org

**Research Objective:** Black women and women with low SES have worse outcomes after breast cancer than other women, and these differences are not fully accounted for by differences in disease characteristics. The objectives of this study were to assess the role of the quality of adjuvant therapy, defined as the receipt of guideline-concordant adjuvant treatment, in the disparities in outcomes.

**Study Design:** Drawing from the universe of women diagnosed with breast cancer in two SEER registries, we selected a random sample stratified by race/ethnicity and vital status. Sampled women were invited by mail to participate in a retrospective study of breast cancer treatment patterns and outcomes. One registry required that family members of deceased women be approached for consent, while the other registry did not. Once consent was obtained, physicians involved in the women’s treatment were contacted to request access to their medical records for abstraction by trained SEER staff. We abstracted data from surgical, radiation therapy, and oncology charts. We contacted primary care physicians for long-term follow-up information as necessary. Data collected included subject socio-demographic characteristics, type of insurance, tumor characteristics, treatment course, detailed radiation and chemotherapy dosing information, timing of treatments, breast cancer recurrences and vital status in 2012. We developed measures of the quality of adjuvant treatment, including the guideline-concordant receipt of...
Chemotherapy, radiation therapy and endocrine therapy based on guidelines in place at the time of diagnosis. SES was assessed using a composite of 6 measures from the census data at the block group level. Outcomes assessed were recurrence-free survival, event-free survival and overall survival. Weighted Cox proportional hazard models were used to assess whether the observed disparities were reduced when measures of guideline-concordant adjuvant treatment were introduced into the models, controlling for sociodemographic characteristics, tumor characteristics, comorbidities, treatment site, and year of treatment.

**Population Studied:** Women diagnosed with breast cancer 1998-2004 who resided in the catchment area of two SEER registries at the time of their diagnosis.

**Principal Findings:** The analytic sample included 1936 women. Black women experienced worse outcomes than non-Hispanic white women (overall survival HR=1.44 p<.01; event-free survival HR=1.55 p<.001; recurrence-free-survival HR=1.57 p<.001). Race was not significant after controlling for SES, other patient characteristics and disease characteristics. Women in the bottom quartile of SES experienced significantly worse outcomes than women in the highest SES quartile in multivariate analyses (overall survival HR=2.12 p<.001; event-free survival HR=1.90 p<.001; recurrence-free-survival HR=2.07 p<.001). Measures of guideline concordant care were associated with improved outcomes, but did not substantively reduce the association between SES and outcomes.

Conclusion: Observed racial disparities in the receipt of guideline concordant care region specific and are mitigated when controlling for SES and tumor characteristics. Although disparities in the receipt of guideline concordant adjuvant therapy exist, controlling for these do not eliminate disparities in outcome by SES.

**Conclusions:** Observed racial disparities in the receipt of guideline concordant care region specific and are mitigated when controlling for SES and tumor characteristics. Although disparities in the receipt of guideline concordant adjuvant therapy exist, controlling for these do not eliminate disparities in outcome by SES.

**Implications for Policy, Delivery, or Practice:** While efforts to eliminate disparities in the quality of breast cancer treatment may reduce disparities in outcomes among women with breast cancer, these efforts are unlikely to eliminate outcome disparities without broader efforts to improve the health and well-being of low SES women.

**Funding Source(s):** NIH

**Poster Session and Number:** A, #281

**Adverse Patient Safety Events and Complications in Hospital Care: Do Outcomes at the Same Hospital Vary by Payer?**

Christine Spencer, University of Baltimore; Darrell J. Gaskin, Johns Hopkins Bloomberg School of Public Health; Eric T. Roberts, Johns Hopkins Bloomberg School of Public Health

**Presenter:** Christine Spencer, Sc.D., Associate Professor, School of Public Affairs, University of Baltimore, cspencer@ubalt.edu

**Research Objective:** This study uses patient safety quality indicators at the hospital level by payer status and answers the question: do patients at the same hospital receive different quality of care depending on their payer status?

**Study Design:** We conducted a cross-sectional analysis using acute care state inpatient discharge (SID) data from 11 U.S. states. To measure quality, we computed payer specific hospital-level inpatient safety indicators for 15 procedures. The Patient Safety Indicators (PSI) provide information on adverse events and complications experienced after surgery and other procedures. We used version 4.3 of the software provided by the Agency for Health Care Research and Quality to calculate the PSIs. Following AHRQ recommendations to produce stable rates, PSIs were only calculated in hospitals which had at least 30 cases in each payer group. We also used data from the AHA Annual Survey of Hospitals to identify hospital specific characteristics that may impact the quality of care received by payer status. These hospital characteristics included financial well-being of the hospital, safety-net status, teaching status and ownership.

We used t-tests to detect differences in risk-adjusted quality indicators between Private payers and Medicaid, Self-pay, Medicare or other at the individual hospital level. These t-tests were only calculated for hospitals with at least 30 cases for the payer groups being compared. Hospital level regressions were also estimated to identify which hospital characteristics had the most impact on quality of care received by payer status. Using linear regression analysis, we estimated a base model...
using the payer composition of the hospitals’ discharges and a constant term. We then estimated a second model controlling for several hospital characteristics: ownership, bed size, teaching status, patient-to-nurse ratio, health system membership, safety-net status, and percentage of Medicare patients. We also used weighted least squares regression to estimate the association between the percentages of private, Medicare, Medicaid and Lowpay patient discharges and individual PSIs.

**Population Studied:** All inpatient discharges from the following 11 states (AZ, CA, NY, FL, IA, MD, MA, NJ, NC, WA, WI) were obtained for 2006 through 2008. We excluded hospitals with fewer than 100 beds, non-acute care general hospitals and federally owned hospitals.

**Principal Findings:** Preliminary results indicate that there are some differences in risk adjusted adverse events and complications by payer status for certain indicators at the individual hospital level. These differences are especially pronounced for Medicare vs. Private payers and Medicaid vs. Private payers. In both sets of comparisons Medicare and Medicaid patients have worse outcomes than Private patients treated at the same hospital.

**Conclusions:** Our study indicates that within hospital differences in quality exist across payer type. Although the private pay group tends to have lower risk-adjusted mortality on most of the PSI measures, there are several indicators in which private patients do notably worse than the other payer groups. Policymakers should pay particular attention to how well patients fare under various insurance plans, since there does appear to be a difference.

**Implications for Policy, Delivery, or Practice:** Given the observed differences in adverse events and complications by payer status at the individual hospital level, payer specific quality improvement efforts may be warranted. Furthermore patient safety quality data should be collected by payer status for display on hospitals’ quality performance scorecards or dashboards as a tool to promote quality of care. These results are especially significant given the PPACA reliance on Medicaid expansions to improve coverage.

**Funding Source(s):** CWF

**Poster Session and Number:** A, #282

**Socioeconomic Status and Hospital Variation in 30-Day AMI Episode-of-Care Payments**

Steven Spivack, Yale-New Haven Hospital Center for Outcomes Research and Evaluation; Lesli Ott, MA, MA, Yale-New Haven Hospital Center for Outcomes Research and Evaluation; Nancy Kim, MD, PhD, Yale-New Haven Hospital Center for Outcomes Research and Evaluation; Department of General Internal Medicine, Yale University School of Medicine; Xiaoyi Xu, PhD, MA, Department of Obstetrics, Gynecology and Reproductive Sciences, Yale University School of Medicine; Lein Han, PhD, Centers for Medicare and Medicaid Services; Harlan Krumholz, MD, SM, Yale-New Haven Hospital Center for Outcomes Research and Evaluation; Department of Cardiovascular Medicine, Yale University School of Medicine; Susannah Bernheim, MD, MHS, Yale-New Haven Hospital Center for Outcomes Research and Evaluation; Department of General Internal Medicine, Yale University School of Medicine

**Presenter:** Steven Spivack, MPH, Research Project Coordinator, Yale-New Haven Hospital Center for Outcomes Research and Evaluation, steven.spivack@yale.edu

**Research Objective:** Patients of low socioeconomic status (SES) may require greater healthcare resources due to higher disease burden or lack of social support. This could lead to costlier care at hospitals with high proportions of low SES patients. However, studies have also demonstrated that low SES patients are less likely to get expensive invasive procedures for cardiovascular disease, which may shift costs to the outpatient setting. We examined how payments for a 30-day episode-of-care following acute myocardial infarction (AMI) differ for hospitals with higher and lower proportions of Medicaid patients.

**Study Design:** Using Medicare claims, we performed a national study of hospitals with one or more AMI discharges (principal discharge diagnosis of ICD-9 codes 410.xx excluding 410.x2). To create comparable 30-day episode-of-care payments across hospitals, we standardized payments by removing or averaging Medicare-specific geographic and policy payment adjustments associated with each care setting. For each hospital, we calculated a risk-standardized payment (RSP) using hierarchical generalized linear models to isolate any hospital-specific effect and account for clustering of patients within hospitals. We risk-adjusted payments for patient age, history of cardiac procedures, and select comorbidities in the 12 months preceding hospitalization including the index admission, but not
complications of care. Medicaid coverage was used as a proxy for low SES. We limited our analyses to hospitals with 25 or more AMI index admissions and compared RSPs for hospitals with the highest (greater than 30 percent) and lowest (10 percent or less) proportion of Medicaid patients. We also compared the proportion of unadjusted payments attributed to index and post-acute care for these two groups. Data were analyzed using two-sample t-tests (alpha=0.05).

**Population Studied:** Medicare fee-for-service beneficiaries 65 or older hospitalized for AMI in 2008.

**Principal Findings:** Our final sample included 1,864 hospitals. 268 had more than 30 percent of patients with Medicaid coverage and 531 had 10 percent or less. Hospitals with the highest proportion of Medicaid patients had a significantly lower (p less than 0.0001) RSP (mean = 19,962 dollars) than hospitals with the smallest proportion of Medicaid patients (mean RSP = 20,455 dollars). In addition, hospitals with the highest proportion of Medicaid patients spent a significantly lower (p less than 0.0001) proportion of their overall payments during the index admission (mean = 74.5 percent) than hospitals with the lowest proportion of Medicaid patients (mean = 77.4 percent).

**Conclusions:** As a group, hospitals that cared for the highest proportion of Medicaid patients had a lower RSP for a 30-day episode-of-care for AMI. In addition, on average, hospitals that cared for the highest proportion of Medicaid patients spent a lower proportion of 30-day episode-of-care payments for AMI during the index admission but a higher proportion during post-acute care.

**Implications for Policy, Delivery, or Practice:** Lower RSPs for an AMI episode-of-care initiated at hospitals with a greater share of Medicaid patients may be driven by lower rates of invasive procedures. Patients at these hospitals, however, incur greater cost in the immediate post-discharge period. This finding may reflect inherently higher needs for services such as skilled nursing care among low SES patients or may represent compensatory costs for the lower intensity of inpatient care (e.g. follow-up procedures or re-hospitalizations).

Reducing Ethnic Disparities for Colorectal Cancer Screenings
Patricia Stream, UnitedHealth Group; Jack Newsom, ScD, Silverlink Communications

**Presenter:** Patricia Stream, M.S.Ed.,B.S.N., Vice President, Quality Management & Performance, Quality Management & Performance, UnitedHealth Group, patricia_a_stream@uhc.com

**Research Objective:** To identify causes of ethnic disparities in colorectal cancer screening rates and to use these findings to systematically improve preventive care in these hard-to-reach and hard-to-engage populations.

**Study Design:** Through a series of annual communications campaigns starting in 2009 and continuing through today, UnitedHealthcare and Silverlink are working to close gaps in preventive care. Our work reduces health disparities for colorectal cancer screenings and tests the effectiveness of several strategies to motivate behavior. We use predictive algorithms to project ethnicity, and our interventions test voice gender, ethnically framed messaging, barriers, channel sequencing, and cultural beliefs messaging. We are currently evaluating 2012 results to assess the efficacy of technology-assisted care management and gender-specific messaging.

Our campaigns target members who have not participated in recommended screenings. We use engaging, personalized and ethnically framed messages; emphasize the importance of screenings; and help individuals overcome barriers to care. Claims data is used to measure the effectiveness of each strategy in motivating screenings.

**Population Studied:** The population studied includes Caucasians, Asians, Hispanic-Latinos and African Americans, representing 647,440 people. The number studied each year varies. In 2009, we targeted 51,017; in 2010, 23,057; in 2011, 103,553; and in 2012, 469,813. Control groups and comparison groups are used to measure the impact of each intervention.

**Principal Findings:** Use of ethnically framed messaging and voice gender in 2009 improved screening rates by 56% versus a control group. A male voice improved screening rates among Hispanics by 89%, while ethnic-framed messages improved screening rates among Hispanics by 10%.

Our 2010 intervention tested communications sequencing, and our findings show that a call
followed by a letter was 43% more effective in driving screenings across the entire population. In 2010, screenings among Hispanics improved 20% versus a comparison group. In 2011, cultural-beliefs messaging resulted in overall screening rate improvement of 42% versus a comparison group. There was a 5% screening rate improvement for African Americans when a cultural-beliefs message emphasizing self-efficacy was used. If selected for presentation, results from our 2012 intervention will be included in our findings, where we test integration of technology and care management ("high-tech and high-touch") and gender-specific messaging. 

Conclusions: Through a series of test-and-learn interventions, with control and comparison groups, measurable improvements in colorectal cancer screening rates can be achieved across ethnic populations. Predictive algorithms can be used to successfully project ethnicity and subsequently measure the impact of interventions to close gaps in care. Our systematic approach includes leveraging consumer marketing principles such as barrier collection, personalized messaging, and a test-and-learn methodology. By collecting barriers and comparing results across ethnic populations, we also identify insights for each ethnic group, and can use this information to inform future outreach.

Implications for Policy, Delivery, or Practice: As a result of our ongoing research, we have recommendations for how to effectively close ethnic disparities related to colorectal cancer screenings, and on a broader level for preventive care. We also believe our recommendations for motivating health behaviors should be considered when ethnic disparities exist for chronic conditions and associated care.

Funding Source(s): Other, United-Healthcare

Presenter: Deborah Swavely, DNP, RN, Administrator, Community Health and Health Studies, Lehigh Valley Health Network, deborah.swavely@lvh.com

Research Objective: Low health literacy (LHL) is more prevalent in persons with limited education, members of ethnic minorities, and those who speak English as a second language. Multiple studies have linked LHL to adverse health outcomes, increased hospitalizations, and higher utilization of emergency care. This is especially true in the context of chronic disease, such as diabetes, where self-management skills are a critical component of care. Individuals with diabetes and LHL have been shown to have poorer knowledge of disease processes and methods for managing their disease. Studies examining the impact of LHL on diabetes outcomes have shown LHL to be an independent predictor of poor glycemic control, higher rates of retinopathy, and more frequent episodes of hypoglycemia.

The objective of this study was to examine the effectiveness of a LHL and culturally sensitive diabetes education program in improving knowledge, self-care behaviors, self-efficacy, and A1C for economically and socially disadvantaged adult patients with type 2 diabetes.

Study Design: Short term outcomes were observed prospectively over twelve months for patients who completed a culturally sensitive LHL diabetes education program. The program was provided by diabetes educators who received training on LHL education and cultural sensitivity. It consisted of both individualized and group diabetes education in English and Spanish languages for adults with type 2 diabetes, encompassing 13 hours of education over 12 weeks. The U.S. Diabetes Conversation Maps and curriculum were used for group classes, with education on diet and medications offered as individualized sessions. Health literacy was measured using the STOFLHA. Outcome data were collected using patient surveys and clinical lab values.

Population Studied: Adult patients with type 2 diabetes referred to the program from primary or specialty care practices.

Principal Findings: Overall, 77.4 percent of the patients were Hispanic, mostly Puerto Rican, living in the United States for longer than 10 years, and preferred to speak Spanish. The mean age was 56.8; 66 percent were female. Over 87 percent of the patients had Medicare or
Medicaid and 12 percent had no insurance coverage. Most patients were low income and nearly half did not have a High School Diploma. At baseline 63.2 percent of patients had adequate health literacy, with 11.3 percent of patients scoring in the marginal, and 25.5 percent of patients in the inadequate health literacy categories. Over the study period 277 patients were enrolled in the program, with 106 participants completing survey data. At the completion of the program patients had significant improvements in diabetes knowledge (p=0.001), self-efficacy (p=0.001), and three domains of self-care including diet (p=0.001), foot care (p=0.001), and exercise (p=0.001). There were no significant improvements in blood glucose testing (p=0.345). Additionally, A1C values significantly improved three months after completing the program (p=0.007).

**Conclusions:** A diabetes education program designed to be culturally sensitive and meet the needs of individuals with LHL improves short term outcomes.

**Implications for Policy, Delivery, or Practice:** It is essential for diabetes education programs, specifically for patients who are socially and economically disadvantaged, to be culturally sensitive and address LHL needs.

**Perceptions of Postpartum Traditions, Postpartum Depression, and Help-Seeking among Vietnamese American Mothers**

Van Ta Park, San Jose State University; Deepika Goyal, San Jose State University; Hong Lien, San Jose State University; Ninh Le, San Jose State University; Denise Rosidi, San Jose State University

**Presenter:** Van Ta Park, Ph.D., M.P.H., Assistant Professor, Health Science, San Jose State University, van.ta@sjsu.edu

**Research Objective:** Postpartum depression (PPD) is a leading cause of maternal morbidity affecting 20-65% of mothers worldwide. There is limited representation of Asian Americans (AA), including Vietnamese, in research. This is concerning because research suggests that AA underutilize mental health services. Furthermore, AA are the fastest growing racial minority population in the U.S. and Vietnamese comprise one of the largest AA subgroups. The research objective of this study is to gain insight on Vietnamese American mothers’ perceptions of postpartum traditions, PPD, and help-seeking.

**Study Design:** This mixed methods study was conducted in Northern California. This study comprised of semi-structured interviews and quantitative surveys (demographic survey, health services questionnaire, Edinburgh Postnatal Depression Scale (EPDS)). An EPDS score of 10 or greater suggested PPD. Vietnamese participants were recruited through flyers, emails, and providers. Interviews were conducted in English and Vietnamese. Participants were asked to describe how PPD is viewed in their culture, their postpartum traditions and help-seeking attitudes and behaviors including health services utilization. Quantitative analyses included descriptive statistics. Qualitative analyses were performed using NVIVO, and content analysis was conducted.

**Population Studied:** A convenience sample of 15 Vietnamese mothers who had delivered a single live infant in the past year participated in this study. All mothers were married and the mean age was 32.3 (SD=4.3) years. The number of years mothers said they have been living in the U.S. ranged from 5-35 with a mean of 18 (SD=8.6). Most of the mothers (93%) were born in Vietnam, half (53.3%) reported being employed full-time, 40% were on maternity leave, and 6.7% were unemployed. Four out of five mothers reported college as their highest level of education with the remaining mothers reporting high school education (6.7%) and degree graduate education (13.3%). Nearly half of the interviews were administered in Vietnamese (46.7%).

**Principal Findings:** Total EPDS score ranged from 0-16, and the mean score was 7.2 (SD=5.4). Overall, 33.3% had an EPDS score of 10 or greater, which indicates a high risk of developing PPD. Mothers reported that postpartum traditions played important roles in their well-being as well as maintaining strong cultural values. However, many reported feelings of isolation and desiring experiencing postpartum traditions more frequently. Some mothers reported that PPD is not understood in their culture. However, all reported that they would seek professional help if needed, but only if their sadness/depression was severe and/or as a last resort given the cultural barriers to help-seeking. Many mothers preferred to use other methods to treat sadness/depression such as seeking social support. Mothers also reported...
that there were cultural barriers to help-seeking such as stigma and shame.

**Conclusions:** Findings of this study revealed that one third of the Vietnamese mothers reported experiencing PPD symptoms. Additionally, findings revealed that Vietnamese mothers were more likely to seek alternative help for depressive symptoms and that PPD was not understood or addressed in their culture.

**Implications for Policy, Delivery, or Practice:** Future PPD interventions should consider the importance of postpartum cultural traditions and the presence of cultural barriers to help-seeking as ways to prevent the adverse effects of untreated PPD to the mother and baby.

**Historical Trend in the Disparity Implications of Applying Medicare MTM Eligibility Criteria among the Non-Medicare Population**

Junling Wang, University of Tennessee; Yanru Qiao, University of Tennessee

**Poster Session and Number:** A, #286

**Research Objective:** Previous studies reported that racial and ethnic minorities would have lower likelihood of meeting the Medicare eligibility criteria for medication therapy management (MTM) services than non-Hispanic Whites (Whites) among the non-Medicare population. This study aims to determine whether the MTM eligibility criteria would perform better in the future by examining the historical trend of MTM disparities from 1996-1997 to 2007-2008.

**Study Design:** Retrospective observational data analysis.

**Population Studied:** This study analyzed the non-Medicare adult population from the Medical Expenditure Panel Survey from 1996-1997 to 2007-2008. Proportions and the odds of meeting MTM eligibility criteria were compared between Whites and two minority population, non-Hispanic Blacks (Blacks) and Hispanics using chi-square test and logistic regression. The trend of disparities was examined by including in regression models interaction terms between the racial and ethnic groups and the latter time period. MTM eligibility criteria used by health plans in 2008 and 2010-2011 were examined. Main and sensitivity analyses were conducted to represent the entire range of the eligibility thresholds used by health plans.

**Principal Findings:** According to the main analysis examining the performance of 2010 eligibility criteria in 1996-1997, the proportions of meeting MTM eligibility criteria among Whites, Blacks, and Hispanics were 5.19%, 3.67%, and 5.43% (p>0.05 for the comparison between Whites and each of the other groups). After adjusting for patient characteristics, Blacks and Hispanics had odds ratios for MTM-eligible of 0.52 (confidence interval: 0.34-0.81) and 0.94 (confidence interval: 0.61-1.44) compared to Whites. No evidence was found to support a change over time in these disparity patterns. Sensitivity analyses and analyses examining 2008 eligibility produced similar findings as above.

**Conclusions:** Racial disparities in meeting MTM eligibility criteria may not decrease over time unless MTM eligibility criteria are changed.

**Implications for Policy, Delivery, or Practice:** Medicare MTM eligibility criteria may not be followed by the non-Medicare population.

**Does a Physician's Attitude towards a Patient with Mental Illness Affect the Clinical Management of Diabetes? Results from a Mixed Method Study**

David C. Henderson, MD, Massachusetts General Hospital and Harvard Medical School; Lisa Welch, New England Research Institutes; Lisa C. Welch, PhD, New England Research Institutes; Heather J. Litman, PhD, New England Research Institutes; Christina P.C. Borba, PhD, MPH, Massachusetts General Hospital and Harvard Medical School

**Presenter:** Lisa Welch, Ph.D., Director, Center for Qualitative Research, New England Research Institutes, lwelch@neriscience.com

**Research Objective:** To determine whether physician attitudes towards patients vary by mental health comorbidity and whether this affects clinical management of a chronic condition (type 2 diabetes).

**Study Design:** A randomized factorial experiment in which physicians observed video vignettes of an established patient presenting with diagnosed but uncontrolled diabetes. Vignette patients were systematically varied by age, gender, race, and comorbidity type (depression, schizophrenia with normal affect
Verbal presentation was standardized. After viewing the vignette, respondents participated in a structured interview, wrote a chart note, and engaged in a semi-structured qualitative interview. Quantitative measures of physician attitudes towards the patient included four subscales: Ability to Manage Health, Personal Attributes (competence, warmth, etc.), Willingness to be Socially Connected with the Patient, and Patient’s Danger to Self/Others. Quantitative outcomes included number of each clinical action (tests, medications, advice); attention to glycemic control; and screenings for diabetes complications (cardiovascular disease, nephropathy, retinopathy, neuropathy, foot care). ANOVA models tested differences in attitude subscales by comorbidity, adjusting for patient, physician, and organizational characteristics. Linear regression models tested for relationships between attitude subscales and clinical actions. The qualitative interview addressed respondents’ impressions of the vignette patient, additional information they would include in the chart note if time permitted, and what they would discuss with a colleague that they did not include in the chart note. Qualitative thematic analysis was conducted by comorbidity group.

**Population Studied:** 256 primary care physicians

**Principal Findings:** Physicians rated patients with SBA lowest on the Personal Attributes subscale ($F=8.60, p<0.001$) and highest on the Danger subscale ($F=11.79, p<0.001$). Differences in attitudes that were attributable to comorbid mental illness (particularly SBA) did not predict management of diabetes as measured quantitatively, but qualitative data revealed differences in management of patients with SBA. Mental health co-morbidities generally increased engagement with patients about social history; however, physicians appeared to have less trust that patients with SBA would or could give reliable information, leading to more reliance on other sources rather than engaging the patient in his/her care. Additionally, physicians were more likely to tell colleagues about a schizophrenia diagnosis when the patient had a bizarre affect, thereby shaping expectations about the patient before interactions occurred.

**Conclusions:** Results are consistent with common stereotypes about people with serious mental illness, including perceptions of violent behavior. Importantly, comorbidity was the only difference across vignettes, and none of the vignettes included intentional indication of danger or unreliable reporting. Subtle differences in management of patients with comorbid SBA led to reduced engagement with them about their care and heightened risk of stigmatized interactions with staff, potentially leading to disparate quality of care over time. Different management of patients with SNA vs. SBA suggests that affect is an important contributor to variation in care.

**Implications for Policy, Delivery, or Practice:** Despite medical training, physicians are not immune to common stereotypes that can shape behavior, thereby potentially perpetuating these stereotypes. Reducing healthcare disparities requires attention to the more subtle aspects of managing patients—particularly those with an atypical affect—as seemingly slight management differences can engender disparate patient experiences over time.

GENERAL POSTERS

Identifying Barriers and Facilitators of Participation in a Population-Based Hypertension Management Program
Joseph Agostini, Aetna Medicare; Vanessa Flint, Aetna Medicare; Aaron Morel, Lucid Health; Randall Krakauer, MD, Aetna Medicare

Presenter: Joseph Agostini, M.D., Senior Medical Director, Aetna Medicare, agostinij@aetna.com

Research Objective: Less than half of people with hypertension in the U.S. are under adequate control. The Aetna Medicare Advantage Hypertension program identifies Medicare members with hypertension, from a total population of over 600,000. Members are invited to participate voluntarily and receive an automated blood pressure monitor along with monthly interactive voice response (IVR) calls for one year. Members self-report blood pressure measurements over the phone and receive automated feedback on results, and live nurse case management outreach, if indicated. Initial program implementation resulted in a 19% participation rate and statistically significant improvements in systolic and diastolic blood pressure outcomes and transition from inadequate to adequate control. The purpose of this qualitative study was to identify the barriers and facilitators of program participation in order to improve invitation materials and increase future participation rates.

Study Design: Qualitative study with telephonic and in-person focus group interviews to the point of thematic saturation, with Medicare members in Pennsylvania and New Jersey who were either: eligible but chose not to enroll, or currently enrolled hypertensive members.

Population Studied: 17 Medicare members, aged 65 years and older, with hypertension as defined by a claims-based algorithm using data such as pertinent hypertension diagnosis billing codes and recurrent prescription medication use.

Principal Findings: Among enrollees, facilitators of program participation included several themes: the receipt of a blood pressure monitor at no cost; a desire to be healthy; and a desire to live longer to be with family (e.g., grandchildren). Continued participation in the program for enrollees was facilitated by two common themes: the helpfulness of a reminder to check their blood pressure on a regular basis and track it via IVR; and the potential or reality of observing positive improvements in blood pressure measurements over time. Among non-enrollees, a common theme was limited or no recall of the invitation letter. A key barrier to participation was the belief among hypertensive patients that their blood pressure is adequately controlled, and, therefore, the program is not personally relevant or necessary. After reviewing the invitation materials again as part of the interview, non-enrollees cited the following factors that would improve their decision-making on program participation: more information on the free blood pressure monitor, citation of actual program results (e.g., change in blood pressure); the inclusion of motivating quotations from past program participants, with emotional- and rational-centered quotations rated as most compelling; and the presence of pictures included in the written, text-based invitation materials.

Conclusions: Identification of common barriers and facilitators of participation in this scalable, population-based health program for hypertension can be used to iteratively refine invitation and marketing materials.

Implications for Policy, Delivery, or Practice: Given the previously reported improvements in blood pressure outcomes that can occur with program participation, it is imperative to encourage widespread participation in a low cost program for older adults that decreases the risk of adverse cardiovascular outcomes for those with a potentially controllable risk factor.

Temporal Trends in Lyme Disease Diagnosis Rates by Gender and Health Plan
John Aucott, Johns Hopkins University School of Medicine; Lin Wang, Johns Hopkins HealthCare; Shannon Murphy, Johns Hopkins HealthCare; Jill Marsteller, Johns Hopkins Bloomberg School of Public Health; Maria Uriyo, Johns Hopkins HealthCare; Alyson Schuster, Johns Hopkins HealthCare; Alison Rebman, Lyme Disease Research Foundation; Peter Fagan, Johns Hopkins School of Medicine

Presenter: John Aucott, M.D., Assistant Professor Of Medicine, Medicine, Johns Hopkins University School of Medicine, jaucott2@jhmi.edu

Research Objective: To determine whether rates of first Lyme disease diagnosis vary by
gender, month of diagnosis, and type of health plan among a large sample of patients enrolled in either a Medicaid managed care organization or a commercial health plan.

**Study Design:** This retrospective study selected all members of a Medicaid managed care organization (MMCO) and a commercial health plan (CHP) between 2 and 65 years old who had an ICD-9 diagnosis of Lyme disease between July 1, 2004 and June 30, 2011 (the study period) based on medical claims data. For each study subject, the date of the first record of the Lyme disease diagnosis (FRLDD) in the claims data was recorded. A FRLDD rate was calculated for both health plans, and for each month in the study period. The FRLDD rate was defined as the number of plan members with FRLDD per 100,000. Mean FRLDD rate for each of the 12 months over the study period was calculated for the following strata: type of health plan (MMCO vs. CHP), and male/female groups within a health plan.

**Population Studied:** Medicaid beneficiaries and commercial health plan enrollees who were between 2 and 65 years old were included in the study.

**Principal Findings:** There were 348,445 unique MMCO members (58% female) and 112,057 unique CHP members (57% female) between 2 and 65 years old during the study period. Of the MMCO members, 912 (0.26%) were identified with FRLDD, of which 525 (58%) were women. Of the CHP members, 556 (0.50%) had a FRLDD, and 304 (55%) were women. For both MMCO and CHP, mean FRLDD rate showed an upward trend from January (3.7 and 6.4, respectively) to June (17.8, 35.0), followed by a downward trend to December (3.3, 5.8). The mean FRLDD rate in MMCO appeared lower than that in CHP. In addition to the seasonal pattern, the female group in both MMCO and CHP presented a slower downward trend of mean FRLDD rate than the male group. The FRLDD rate was higher among men during peak summer months, but higher among women in September to December.

**Conclusions:** The known seasonality of acute Lyme exposure is reflected in the upward trend in mean FRLDD rate for both plans during the spring and summer and the downward trend in the fall and winter. The observed difference in overall FRLDD between CHP and MMCO may reflect rural/urban or socioeconomic differences between members of the two groups. The higher FRLDD rate during fall months among women is previously unreported in the literature, and may represent gender-based differences in time to diagnosis, behavioral risk factors, provider bias or false positive diagnoses.

**Implications for Policy, Delivery, or Practice:** Clinical policy and practice have increasingly stressed consideration of gender-based differences for a range of disease settings. Our findings imply a previously unreported gender difference in Lyme disease diagnosis by month. As such, they would have important implications for future guideline development and suggest a need for continued research investigating not only the clinical implications of potential delayed diagnosis among women, but also gender-based patterns in care utilization and cost.

**Six-Month Cost Avoidance Analysis Associated with Reducing Hospital Readmissions Using The Care Transitions Intervention**

Rosa Baier, Healthcentric Advisors and Warren Alpert Medical School of Brown University; Qijuan (Emily) Li, MPH, Warren Alpert Medical School of Brown University; Rebekah Gardner, MD, Healthcentric Advisors and Warren Alpert Medical School of Brown University; Kristen Butterfield, MPH, Healthcentric Advisors; Eric Coleman, MD, University of Colorado; Stefan Gravenstein, MD, MPH, Healthcentric Advisors and Warren Alpert Medical School of Brown University

**Presenter:** Rosa Baier, M.P.H., Senior Scientist, Healthcentric Advisors and Warren Alpert Medical School of Brown University, rbaier@healthcentricadvisors.org

**Research Objective:** To evaluate the cost avoidance associated with implementation of the Care Transitions Intervention (CTI) in six hospitals in Rhode Island, and to provide benchmarks for financial outcomes from hospital readmission reduction programs such as the CTI.

**Study Design:** We used Rhode Island Medicare Part A and Part B claims data from January 1, 2009 through December 31, 2011 to evaluate utilization and costs using an episode-based approach, comparing patients who received the CTI (intervention group) to those who were offered the intervention, but declined to participate or were lost to follow-up before completing a central element of the intervention,
the home visit (control group). First, we used a one-to-one matching propensity score to control for differences between the intervention and control groups in the six months prior to hospital discharge (baseline). Key control variables included year, age, sex, race, dual eligible status and pre-existing conditions and comorbidities based on the CMS Hierarchical Condition Category model. Second, we examined episode-based bundled utilization and costs in the six-month period following hospital discharge. Utilization included 30-day readmissions and emergency department visits and observation stays per 1,000 Medicare beneficiaries; costs also included other outpatient visits, professional charges and post-acute care. Finally, we estimated cost avoidance by calculating gross differences between the intervention and control groups and subtracting intervention costs.

**Population Studied:** The CTI was implemented by Healthcentric Advisors, the Medicare Quality Improvement Organization for the state of Rhode Island. Our study population was fee-for-service Medicare patients hospitalized in six Rhode Island hospitals recruited to receive the CTI between 2009 and 2011. Initially, subject eligibility was based primarily on admission diagnoses for specific cardiac and respiratory conditions; after January 2010, increased intervention capacity allowed us to expand eligibility to include all admission diagnoses. We excluded subjects with limited English proficiency, with cognitive impairment (unless a caregiver was able to act as a proxy) and whose discharge plans included a nursing home or hospice.

**Principal Findings:** This study included 357 patients who received the CTI intervention and 1,033 controls who declined or did not complete the intervention. In this analysis, we used multivariate adjustment by subclassification on the propensity score to identify 357 matches from the control group for the 357 cases in the intervention group. Compared with the control group, the intervention group has lower rates of six-month hospital readmissions, emergency department visits and observation stays. The lower rates of emergency department visits and observation stays suggest less cost-shifting occurred in the intervention group. The intervention group also has lower overall costs for all services with the exception of professional costs (e.g., physician costs), which were higher than in the control group. Overall, we estimate the net cost avoidance at $532 per case per month (adjusted) for intervention subjects compared to the matched control subjects.

**Conclusions:** In this real-world implementation of the CTI, the intervention appears to result in avoided costs over the six-month period following discharge for an index hospitalization.

**Implications for Policy, Delivery, or Practice:** The bundled utilization and cost measures used in this analysis not only help to estimate the CTI’s cost avoidance, but also give healthcare providers and policymakers useful information and metrics to evaluate the impact and cost avoidance of hospital readmission reduction programs. These findings are particularly timely given the widespread adoption of readmission interventions, including the CTI; e.g., in Medicare-funded ACA Section 3026 Community-Based Care Transitions Programs, bundled payment approaches and Accountable Care Organizations.

**Poster Session and Number:** C, #911

**Patterns of Healthcare and Associated Costs in Medicare Beneficiaries with Schizophrenia: An Opportunity for Improvement?**
Robert Bailey, Janssen Services, LLC; James Muller, The Moran Company; John Fastenau RPh, MPF, Janssen Services, LLC; Rachel L. Feldman MPA, The Moran Company

**Presenter:** Robert Bailey, M.D., Director, Janssen Services, LLC, rbailey5@its.jnj.com

**Research Objective:** To evaluate healthcare patterns and associated costs in Medicare beneficiaries with schizophrenia (MBS) prior to and following a non-psychiatric related emergency room visit (ER) or inpatient hospitalization (IP).

**Study Design:** This retrospective, observational study used the 2009 and 2010 Medicare Standard Analytic Files to evaluate healthcare utilization and associated costs. MBSs with an index non-psychiatric ER or IP encounter from 7/1/2009-6/30/2010 were included. Patterns of healthcare and associated costs prior to and after the index event (3 months for ER/6 months for IP) were evaluated and compared. In MBSs with multiple encounters, the first encounter was used. Healthcare payments included all services except Part D prescription drug costs and were standardized to 2010 US dollars. Healthcare payments were categorized as pre-index, during index, and post-index encounter.
**Population Studied:** Community dwelling Medicare beneficiaries with schizophrenia.

**Principal Findings:** 5,660 MBSs were identified (4,528ER/1,132IP). Mean(SD) age was 49(14), 59% were male, 79% resided in metropolitan areas, and 77% received low income subsidies for Medicare premiums (proxy for dual eligibility). The most common comorbidities for ER were injury, hypertension, tobacco abuse, diabetes, and cardiac disease and for IP were metabolic disorders, hypertension, cardiac disease, diabetes, and injury. The most expensive comorbidities for ER were kidney disease, urinary tract infection, and diabetes; for IP were kidney disease, abdominal pain, pneumonia, and injury. For ER, the mean(SD) per beneficiary month outpatient physician encounters 3 months prior/post index encounter were Medical: 0.66(10.0)/0.83(10.9) representing a 25% increase, and Psychiatric: 0.51(9.6)/0.58(9.8) representing a 13% increase. For IP the mean(SD) per beneficiary month outpatient physician encounters 6 months prior/post index encounter were Medical: 0.81(13.7)/0.98(14.2) representing a 22% increase and Psychiatric 0.48(13.0)/0.53(12.3) representing an 11% increase. The frequency of outpatient physician encounters for both medical and psychiatric encounters approached baseline after 3 months for ER and 6 months for IP. Mean(SD) healthcare payments per beneficiary month for ER were: pre $910($21,578), during $598($543), post $1,163($29,968), during $12,528($15,463), post $3253($127,633) representing an 11% increase. The frequency of outpatient physician encounters for both medical and psychiatric encounters approached baseline after 3 months for ER and 6 months for IP. Mean(SD) healthcare payments per beneficiary month for ER were: pre $910($21,578), during $598($543), post $1,163($29,968), during $12,528($15,463), post $3253($127,633) representing a 180% increase from pre to post.

**Conclusions:** Non-psychiatric Emergency Room and Inpatient Hospital encounters are associated with a significant increase in healthcare resource utilization and associated costs. The pattern of increased outpatient visits approaches baseline within 6 months of the index encounter, suggesting a potential repetitive cycle of disengagement from the healthcare system. Most of the frequent and costly comorbidities are chronic diseases such as hypertension, diabetes, cardiac disease, and kidney disease. Regular contact with the healthcare system may improve outcomes, lessen the need for ER or IP care, and lower costs.

**Implications for Policy, Delivery, or Practice:** Identification of ways to engage Medicare beneficiaries with schizophrenia in healthcare and to maintain regular contact with the healthcare system may offer opportunities to lower healthcare costs.

**Funding Source(s):** Other, Janssen Services, LLC

**Poster Session and Number:** C, #912

**Hospital Utilization in Persons with Down's Syndrome**

Kathy Belk, MedAssets; Chris Craver, MedAssets

**Presenter:** Kathy Belk, Senior Manager, Health Data Analytic, MedAssets, kbelk@medassets.com

**Research Objective:** Down’s syndrome is a genetic disorder affecting approximately one out of every 700 babies born in the US each year. Individuals with Down’s syndrome have a higher risk of heart defects, respiratory illness and other health issues which vary in severity across individuals. The purpose of this analysis is to examine inpatient and outpatient hospital utilization for this patient population.

**Study Design:** Descriptive methods were used to perform a retrospective analysis examining inpatient admissions and outpatient visits as well as patient characteristics for this patient population. One way analysis of variance was used to test for differences between groups for continuous variables.

**Population Studied:** The study population includes 56,025 patients with a diagnosis of Down’s syndrome across 455 hospitals submitting to the MedAssets health system data for the January 2008 to December 2012 timeframe. Patients were limited to hospitals submitting data for 12 months to be included in the analysis for that year.

**Principal Findings:** This patient population had an average of 1.4 inpatient admissions and an average of 3.3 outpatient visits per year. The frequency of hospitalization increased with age with 1.3 admissions per year for patients less than a year old, 1.4 admissions for ages 1-18, 1.4 admissions for ages 19-40, 1.5 visits for ages 41-65, and 1.6 visits per year for those over the age of 65 (p < .0001). This effect was more pronounced in the outpatient setting where individuals over the age of 65 had 4.9 outpatient visits annually compared to 3.9 for those less than a year, 3.3 for age 1-18, 2.7 for age 19-40, and 3.3 for those between 41 and 65 (p < .0001). No differences were found in frequency of hospitalization between males and females.
Most admissions were for medical conditions (81.3%) with more than half of the conditions for patients over the age of 1 being for respiratory disease (25.3%), digestive conditions (10.6%), circulatory disorders (9.1%), and infectious diseases (8.1%). The length of stay for hospitalizations were the highest for patients less than a year in age (12.0 days) and those greater than age 65 (8.4 days) compared to patients between the ages of 1 and 18 (6.6 days), 19 and 40 (6.6 days) and 40-65 (7.3 days).

**Conclusions:** Persons with Down’s syndrome visit the hospital for a multitude of reasons. Frequency of hospital use increases with age in persons with Down’s syndrome. One limitation of the administrative data used for this analysis is that patients could not be tracked across hospitals therefore utilization is limited to same-hospital visits.

**Implications for Policy, Delivery, or Practice:**
Over the last twenty years the life expectancy has greatly increased among individuals with Down’s syndrome. As life expectancy increases so do the medical conditions requiring treatment in the hospital setting. Understanding treatments for these conditions in an aged Down’s syndrome population will become more important over time.

**Payment for Healthcare Services Differs Depending on the Type of Providers:**

**Results from the National Hospital Ambulatory Medical Care Survey**
Joseph Benitez, University of Illinois at Chicago; Bettie Coplan, MPAS, PA-C, College of Health and Human Services, Northern Arizona University Phoenix - Biomedical Campus; Roderick S. Hooker, PhD, PA, The George Washington University School of Public Health and Health Services; Richard Dehn, MPA, PA-C, College of Health and Human Services, Northern Arizona University Phoenix - Biomedical Campus

**Presenter:** Joseph Benitez, MPH, PhD Candidate, Health Policy and Administration, University of Illinois at Chicago, jbenit3@uic.edu

**Research Objective:** The source of payment for health care services depends on a number of factors and varies widely depending on employment and geography. Growing evidence suggests that source of payment may be associated with type of provider. In this study, we examine source of payment by physician, physician assistant (PA), and nurse practitioner (NP).

**Study Design:** A pooled cross-sectional analysis of 132,000 patient visits from the National Hospital Ambulatory and Medical Care Survey (NHAMCS) during the time period. Binary logistic regression models were used to estimate the probability of treatment for each source of payment by provider seen. The sources of payment under observation included 1) Private/Managed Care, 2) Medicare, 3) Medicaid, 4) Worker’s Compensation, 5) Self pay, and 6) No charge (i.e. uncompensated/charity care).

**Population Studied:** A nationally representative sample that represents more than an estimated 36 million outpatient department hospital visits between 2005-2010.

**Principal Findings:** Compared to physicians, PAs were nearly twice as likely to treat patients whose primary source of payment was “Workman’s Comp.” Additionally, PAs and NPs were more likely to treat patients who paid out of pocket than were physicians. Physicians were more likely to be the provider for patients whose primary source of payment was private insurance, Medicaid, or Medicare.

**Conclusions:** Our findings suggest that triage of services to PAs and NPs may be occurring when patients are uninsured.

**Implications for Policy, Delivery, or Practice:**
Even after accounting for patient characteristics including severity of patient health status (proxy measured using number chronic conditions), the relationship remains consistent. These results provide some evidence of a division of labor among health care providers with respect to patients’ primary source of payment.

**The Effects of Geographic Concentration of Insurance Coverage on Access and Health Outcomes – Implications for How the Affordable Care Act’s Insurance Expansions Will Improve Access and Quality of Care**
Julia Berenson, The Commonwealth Fund; Cara Dermody, The Commonwealth Fund

**Presenter:** Julia Berenson, MSc, Senior Research Associate, The Commonwealth Fund, jb@cmwf.org
Research Objective: Currently, more than 48 million people are uninsured in the United States (U.S.), many of whom are low-income, racial and ethnic minorities, and otherwise vulnerable populations. The Patient Protection and Affordable Care Act (Affordable Care Act) will significantly reduce the number of uninsured adults with the expansion of Medicaid eligibility and the creation of new subsidized insurance coverage options through health insurance exchanges. Extending insurance coverage to populations is a critical and necessary step in improving access to quality health care. Recent research has demonstrated that state Medicaid expansions similar to those under the Affordable Care Act were associated with positive changes in access to care, health care use, financial strain, mortality, and other health outcomes for low-income adults. However, evidence regarding the geographic concentration of insurance coverage’s effect on access and health outcomes for populations within a region remains sparse. It will be important to understand the effects of geographic concentration of insurance coverage since states have some flexibility in the design of their exchanges and whether to expand Medicaid eligibility, which may have the unintended consequence of variation in insurance coverage across regions in the U.S. This analysis examines whether geographic areas with a high concentration of insured adults are significantly associated with improved rates of access and health outcomes for populations.

Study Design: The geographical unit of analysis is the hospital referral region (HRR), created by the Dartmouth Atlas of Health Care project. HRRs represent regional markets for tertiary medical care and include a city with at least one medical center that serves as a referral hospital for tertiary care. There are 306 HRRs across the U.S. Using national data from the Behavioral Risk Factor Surveillance System (BRFSS), Community Health Status Indicators (CHSI), and the American Community Survey (ACS), this analysis examines across HRRs the association between the percent of insured adults ages 18-64 (ACS) and various access and health outcomes, including: (1) the percent of adults who reported no cost-related problems with seeing a doctor within the past year (BRFSS); (2) the percent of at-risk adults who visited a doctor for a routine checkup in the past two years (BRFSS); and (3) the percent of live births with low birth weight (CHSI). We define a high concentration of insured adults as HRRs with the percent of insured adults above the national HRR median. Reporting is restricted to statistically significant differences. Using regression analysis, we control for income, race, education, population density, and health status within HRRs.

Population Studied: Data come from the BRFSS, CHSI, and ACS surveys that are based on a random, nationally representative sample of adults living in the U.S. This analysis limits the survey to adult respondents ages 19 to 64 within 306 HRRs.

Principal Findings: HRRs with a high concentration of insured adults are associated with a significantly higher percent of adults who reported no-cost related problems with seeing a doctor within the past year (p<0.05); higher percent of at-risk adults who visited a doctor for a routine checkup in the past two years (p<0.05); and reduced percent of live births with low birth weight (p<0.05). These differences remain statistically significant after controlling for income, race, education, population density, and health status of the HRRs.

Conclusions: Results of this analysis demonstrate that HRRs with a high concentration of insured adults are significantly associated with improved rates of access and health outcomes for populations. Our findings suggest that the geographic concentration of insurance coverage has a significant impact on populations’ health.

Implications for Policy, Delivery, or Practice: Under the Affordable Care Act, 29 million people in the U.S. are expected to gain insurance coverage by 2019. However, there will likely be variation in coverage across geographic areas within the U.S. States have flexibility with regard to the organization of state exchanges and also whether to implement Medicaid eligibility expansions under health reform. State policymakers should be aware that their decisions regarding whether and how to implement such policies concerning insurance coverage expansions will likely have significant effects on the health of populations, particularly low-income and otherwise vulnerable populations.

Does Public Reporting Have an Impact on Healthcare Disparities? A Systematic Review
Zackary Berger, Johns Hopkins School of Medicine; Taruja Karmarkar, Johns Hopkins School of Public Health; Emily Boss, Johns
Hypothesized a supply side effect, whereby minorities used the provided information to choose higher-quality providers. Others hypothesized a supply side effect, whereby hospitals would have a greater incentive to improve quality.

Possible negative relationships were frequently mentioned. On the demand side, some claimed that minorities may find PR data less relevant or harder to use, especially if PR is not tailored to them. On the supply side, disparities could be promulgated if health delivery organizations consciously “cherry picked” healthier patients or avoided certain patients subgroups in order to improve their public reporting measures. Finally, providers might avoid minorities, assuming that their increased risk would be incompletely adjusted for in the context of PR.

Conclusions: Empirical evidence relating PR and disparities is scant. Hypothesized mechanisms for the effect of PR on disparities have been documented in the literature and detailed recommendations for future research have been made.

Implications for Policy, Delivery, or Practice: More resources need to be devoted to understanding minorities’ views of PR, the design and testing of PR tailored to these needs, the impact of PR on disparities in access and patient outcomes. The differential effects of PR on vulnerable groups should be documented and the particular information needs of minorities addressed. Healthcare organizations should aim to improve risk adjustment while striving for fair comparisons, establishing guidelines related to PR for relevant subgroups.

Funding Source(s): No Funding

Poster Session and Number: C, #916

Study Design: We conducted a systematic review of all articles of any design related to public and quality reporting published prior to 2013 in PubMed, Scopus, PsycINFO, Sociological Abstracts, Social Science Citation Index (Web of Science), EconLit and Anthropology Plus. Our review found mixed evidence on the effect of PR on health outcomes. We then reviewed all full text articles for any claims regarding the relationship of PR to healthcare disparities.

Population Studied: Of the 1,967 articles identified, 337 were duplicates, 416 were deleted at title review and 312 at abstract review. Twenty articles met the criteria for inclusion in this review. Twelve articles were commentaries, editorials, or recommendations, 2 were systematic reviews, and 6 were original research.

Principal Findings: Two articles empirically assessed the effect of PR on disparities, one showing little influence on access to care by minorities in the hospital, another finding short-term improved patient sorting by risk in nursing homes. Other articles, spanning original research, systematic reviews, commentaries and editorials, speculated about possible associations between PR and disparities. The most-cited potential positive impact of PR on disparities was a conjectured demand-side effect, that PR would improve disparities as minorities used the provided information to choose higher-quality providers. Others hypothesized a supply side effect, whereby

Research Objective: Public reporting (PR) is a systematic effort to inform healthcare consumers about provider performance. Despite little evidence demonstrating a direct relationship between PR and disparities, competing schools of thought exist arguing that PR may either increase or decrease disparities in access or outcomes. We set out to document and classify all published statements about PR pertaining to a possible causal effect on healthcare disparities, to assess their validity, and to summarize research gaps identified in the literature.

Study Design: We conducted a systematic review of all articles of any design related to public and quality reporting published prior to 2013 in PubMed, Scopus, PsycINFO, Sociological Abstracts, Social Science Citation Index (Web of Science), EconLit and Anthropology Plus. Our review found mixed evidence on the effect of PR on health outcomes. We then reviewed all full text articles for any claims regarding the relationship of PR to healthcare disparities.

Research Objective: To help inform public health policymakers, we examined the cost-effectiveness (CE) of implementing a barbershop-based screening program for hypertensive Black men living in a large metropolitan area, while exploring the impact of varying (1) the program’s effectiveness and (2) the cost of linking a participant to follow-up primary care.

Study Design: A Markov model was developed to evaluate the CE of a blood pressure
screening program at Black-owned barbershops as program characteristics change. The model was motivated by our ongoing clinical trial of hypertension and colorectal-cancer-screening for Black men. We projected the risk of coronary heart disease (CHD), end stage renal disease (ESRD), congestive heart failure (CHF), myocardial infarction, stroke, and all-cause mortality as a function of systolic blood pressure (SBP) and other risk factors. The New York City-Health and Nutrition Examination Survey informed the distribution of patient characteristics and baseline comorbidities. Healthcare costs and health-related quality of life were estimated using Medicare’s hierarchical-condition-categories model and EQ-5D health utilities. The program’s effectiveness and cost of linking a participant to follow-up were informed through our clinical trial and other sources. A societal perspective was adopted with a lifetime horizon and 3% discount rate.

**Population Studied:** Simulated population of 261,349 Black men over the age of 50 living in New York City, 51% of whom have a self-reported income at or below 200% of the poverty level. Fifty-four percent report a highest education level of high school or less.

**Principal Findings:** The CE of the barbershop-based hypertension-screening program varied from $6284 per quality-adjusted life-year (QALY) to $8482 when the impact of the intervention on SBP fell from a reduction of 20 mmHg to 5 mmHg. Similarly, the CE varied from $5828 per-QALY to $7803 per-QALY when the cost of linking a participant to appropriate care increased from $100 to $1,000. The number needed to screen (NNTS) to prevent one case of incident CAD, ESRD, or CHF was 313, 2500, and 834 respectively. The NNTS to prevent any of these conditions ranged from a low of 148 when SBP fell by 20 mmHg to a high of 715 when SBP fell by 5 mmHg. If this program were adopted in all NYC black-owned barbershops (serving approximately 68,054 hypertensive Black men), 217, 28, and 82 cases of CAD, ESRD, and CHF could be prevented and $161,536,654 healthcare dollars would be saved.

**Conclusions:** The CE of the barbershop-based hypertension screening for Black men is sensitive to changes in the cost of linking participants to care, and the overall effectiveness of hypertension control. However, CE ratios remain favorable over a range of program assumptions.

**Implications for Policy, Delivery, or Practice:** Barbershop-based hypertension screening may reduce health disparities. Because hypertension is a disproportionately significant contributor to morbidity and mortality in Black men, innovative approaches to controlling blood pressure in urban communities should be explored.

**The Relationship Between Electronic Health Record Stage 1 Meaningful Use Objectives and Hospital Quality of Care**

Lori Bilello, University of Florida College of Medicine; Christopher Harle, PhD, University of Florida College of Public Health and Health Professions; Jeffrey Harman, PhD, University of Florida College of Public Health and Health Professions; R. Paul Duncan, PhD, University of Florida College of Public Health and Health Professions; Robert L. Cook, M.D., MPH, University of Florida College of Public Health and Health Professions

**Presenter:** Lori Bilello, Ph.D., M.B.A., M.H.S., Associate Director, Center for Health Equity and Quality Research, University of Florida College of Medicine, lori.bilello@jax.ufl.edu

**Research Objective:** As provisioned by the Health Information Technology for Economic and Clinical Health (HITECH) Act, hospitals can qualify for Medicare and Medicaid Electronic Health Records (EHR) incentive payments by achieving EHR Meaningful Use (MU). That policy reflects an assumption that improved use of information technology generally and electronic medical records specifically will result in improved care. This study assessed the relationship between meeting Stage 1 MU objectives and care quality in hospitals.

**Study Design:** We conducted a cross-sectional observational study by collecting survey data from Florida acute care hospitals in August 2010. The survey elicited hospital’s current EHR functionality according to Stage 1 MU measures. The survey data were augmented with ten CMS Hospital Compare quality measures related to heart failure and pneumonia care processes. We used Generalized Linear Model (GLM) regression with a binomial family and a logit link to relate hospital quality scores to the estimated number of MU objectives met. Also, in two separate regressions, we estimated the relationship between quality scores and two specific elements of Meaningful Use that may
have the greatest impact on care processes -- computerized provider order entry (CPOE), and clinical decision support systems (CDSS).

**Population Studied:** The survey population was all Florida licensed acute care hospitals with 162 of 211 Florida acute care hospitals (76.8%) responding to the survey.

**Principal Findings:** The number of MU objectives hospitals met was positively associated with Pneumococcal Vaccination Status (OR = 1.05, p = 0.05), and marginally positively associated with two other pneumonia measures - Initial Antibiotic Timing (OR = 1.03, p = 0.08) and Smoking Cessation Advice/Counseling (OR = 1.09, p = 0.06). One heart failure measure, Evaluation of Left Ventricular Systolic Function (OR = 1.08, p=0.01), also showed a significant positive association. Further, CPOE use was positively associated with two pneumonia measures: Initial Antibiotic Timing (OR = 1.69, p<0.01) and Initial Antibiotic Selection (OR = 1.52, p= 0.01). CDSS use was negatively associated with Discharge Instructions for heart failure patients (OR = 0.40, p= 0.01).

**Conclusions:** Using EHRs in the manner described by federal MU objectives was associated with higher quality for several hospital care processes. Researchers should continue to examine the relationship between meaningful use of EHRs and care quality as the federal EHR incentive program continues.

**Implications for Policy, Delivery, or Practice:** This study showed a modest positive impact of CMS Stage 1 MU objectives on several hospital quality measures in months leading up to the start of the federal EHR incentive program. As the program continues, stronger evidence of quality improvement will be needed to justify the substantial federal investments in EHR adoption and use. Since this study’s data were collected, thousands of hospitals received MU incentive payments and CMS finalized Stage 2 MU criteria. In the coming years, providers and policymakers should carefully monitor whether these adoption increases and more stringent MU criteria produce a stronger impact on care quality.

**Organizational Characteristics Associated with Electronic Health Record “Meaningful Use” in Hospitals**

Lori Bilello, University of Florida College of Medicine; Christopher Harle, PhD, University of Florida College of Public Health and Health Professions; Jeffrey Harman, PhD, University of Florida College of Public Health and Health Professions; R. Paul Duncan, PhD, University of Florida College of Public Health and Health Professions; Robert L Cook, M.D., MPH, University of Florida College of Public Health and Health Professions

**Presenter:** Lori Bilello, Ph.D., M.B.A., M.H.S., Associate Director, Center for Health Equity and Quality Research, University of Florida College of Medicine, lori.bilello@jax.ufl.edu

**Research Objective:** As provisioned by the Health Information Technology for Economic and Clinical Health (HITECH) Act, hospitals can qualify for Medicare and Medicaid Electronic Health Records (EHR) incentive payments by achieving EHR Meaningful Use (MU). This study assessed the impact of having a Chief Medical Information Officer (CMIO) and other organizational characteristics on hospitals’ MU achievement.

**Study Design:** We conducted a cross-sectional observational study by collecting survey data from Florida acute care hospitals in August 2010. The survey elicited hospital’s current EHR functionality according to Stage 1 MU measures. The survey also elicited organizational characteristics including size, ownership status (for-profit versus non-profit), system affiliation, geographical location (rural versus urban), nurse staff to bed ratio, operating margin, CMIO presence, and IT staff to bed ratio. Using Poisson regression, we estimated the relationship between the number of MU objectives met by each hospital and their organizational characteristics.

**Population Studied:** The survey population was all Florida licensed acute care hospitals with 162 of 211 Florida acute care hospitals (76.8%) responding to the survey.

**Principal Findings:** Holding other characteristics constant, hospitals with CMIOs on staff reported achieving 16% or 2.4 more MU objectives than hospitals without a CMIO (IRR = 1.16, p<0.01). Also, urban hospitals met 32% or 4.7 more MU objectives than rural hospitals (IRR= 1.32, p<0.01). Finally, hospitals affiliated with a hospital or healthcare system met 22% or 3.2 more MU objectives than non-affiliated hospitals (IRR = 1.22, p<0.01).

**Conclusions:** This study shows the potential positive impact of a CMIO on hospital MU achievement. While other researchers have
identified organizational factors that are important for health information technology (HIT) adoption, we believe this is the first study to examine the impact of CMIOs on MU achievement across hospitals.

**Implications for Policy, Delivery, or Practice:**
From a policy perspective, hospitals should consider the value of having a CMIO to enhance the successful adoption and meaningful use of HIT systems. CMIOs can provide first-hand knowledge of clinical workflows, informatics skills, and IT expertise to effectively lead complex and challenging EHR implementations.

**Examining the Offer Rates Rates for Retiree Health Benefits**
Nathan Bostick, Health Research & Educational Trust; Matthew Rae, Kaiser Family Foundation; Kevin Kenward, Health Research & Educational Trust

**Presenter:** Nathan Bostick, M.A., M.P.P., Senior Researcher, Health Research & Educational Trust, andybostick@gmail.com

**Research Objective:** The Kaiser Family Foundation and The Health Research & Educational Trust Employer Health Benefits survey assesses annual trends in employer-sponsored health benefits. The survey includes questions about health coverage, premiums, employee contributions, and retiree benefits. This analysis sought to examine the offer rate for retiree health benefits and to determine if employers within the health care industry are more likely to offer health benefits to retirees, as compared to employers within other industries.

**Study Design:** The 2012 survey included 3,326 randomly selected public and private firms with three or more employees. This survey was fielded from January to May 2012 and ultimately attained an overall response rate of 47%. Survey weights were then created to render this sample more nationally representative of all national employers.

**Population Studied:** The weighted population examined within this study consisted of the 48,351 employers with two hundred or more employees who responded to questions as to whether or not they offered retiree health benefits. Employers in this population belonged to the following industries: agriculture, mining and construction (n=1320, 2.7%); manufacturing (n=4575, 9.5%); transportation, communications and utilities (n=2271, 4.7%); wholesale (n=1658, 3.4%); retail (n=1676, 3.5%); finance (n=4642, 9.6%); service (n=24,841, 51.4%); state/local government (n=1860, 3.8%); and health care (n=5507, 11.3%).

**Principal Findings:** Approximately 17.6% of employers within the health care industry reported providing health benefits to their retirees. This proportion was nearly the lowest across all industries, with the exception of the 9.4% offer rate observed within the retail industry. Offer rates for other industries were as follows: agriculture, mining and construction (19.3%); manufacturing (23.7%); transportation, communications and utilities (40.3%); wholesale (24.8%); finance (40.3%); service (19.4%); and state/local government (77.1%). The overall average offer rate across all industries was 24.6%.

However, when controlling for factors such as firm size, location and the presence of union workers, the percentage of part-time workers, the percentage of workers over age 50% and the percentage of low-wage workers (earning less than $24,000 annually), the health care industry was shown to offer health care benefits to retirees at a slightly higher than average rate (p<0.000).

**Conclusions:** The offer rate for retiree benefits appears to vary substantially across different industries, with the rate for the health care industry being comparatively low in absolute terms. However, other organizational and demographic factors are also statistically significant predictors of employers’ offer rates for retiree health benefits. When these factors are taken into consideration, the health care industry appears to offer benefits at a relatively high rate.

**Implications for Policy, Delivery, or Practice:** These findings are significant as health care coverage is strongly associated with health outcomes among patients. However, the availability of retiree health benefits is not uniform across all employers. In view of these significant variations in the offer rates between employers, it would appear that the presence of programs such as Medicare remain essential in providing coverage to individuals who may not otherwise have access to such a benefit.

Operationalizing Asthma Analytic Plan using OMOP Common Data Model
Elias Brandt, American Academy of Family Physicians; Bethany Kwan PhD, MSPH, University of Colorado School of Medicine; Marion Sills MD, Children's Hospital Colorado; Barbara Yawn MD, MSc, FAAFP, Olmsted Medical Center; Monica Federico MD, Children's Hospital Colorado; Lisa Schilling MD, MSPH, University of Colorado School of Medicine

**Presenter:** Elias Brandt, BS, BA, Research Systems Analyst, National Research Network, American Academy of Family Physicians, ebrandt@aafp.org

**Research Objective:** To operationalize an analytic plan designed to model the association between practices’ medical home characteristics and asthma control in children and adults using a database of existing electronic health data structured according to the OMOP V4 Common Data Model.

**Study Design:** The Scalable Architecture for Federated Translational Inquiries Network (SAFTINet) was designed to federate electronic health data to support quality improvement and comparative effectiveness research (CER). Federated databases include existing administrative, clinical (e.g., from electronic health records; EHRs), Medicaid claims and enrollment data, and patient-reported data collected during routine clinical care, which have been harmonized to the Observational Medical Outcomes Partnership (OMOP) common data model (CDM) Version 4. The SAFTINet asthma study is a prospective, longitudinal cohort study, utilizing survey methodologies and secondary use of structured clinical, administrative, and claims data. Variables in the asthma protocol were operationalized using data elements available in an OMOP CDM V4 database.

**Population Studied:** The population consisted of adults and children with asthma cared for in participating primary care practices in SAFTINet. Participating practices are federally qualified health centers representing ~260,000 patients (30% covered by Medicaid), 500 providers, and four safety net healthcare organizations.

**Principal Findings:** To meet the needs of the SAFTINet CER protocols, we collaborated with OMOP to expand the OMOP V2 CDM to include care site, organization, and financial tables, resulting in OMOP CDM V4. OMOP CDM V4 is a person-centered common data model that contains and links data from various sources including EHR and claims databases. The tables in OMOP include person, condition occurrence, drug exposure, visit occurrence, and care site, among others. It was specifically designed to maintain relationships among patients, associated diagnoses, encounters, medications and procedures. The asthma protocol specifies the use of existing EHR and claims data to operationalize key variables in the analysis. The identification of a cohort of children and adults with asthma is based on diagnosis codes available in the condition occurrence table, as well as patient demographics. The primary outcome, evidence of asthma exacerbations, is determined using clusters of “asthma encounters” (condition occurrence and visit occurrence tables), prescribing patterns (drug exposure table), and asthma-related hospitalizations and emergency department visits (visit occurrence and care site tables, available from claims). Suspected confounders, such as race/ethnicity and asthma severity, are operationalized using the person table and the drug exposure table.

**Conclusions:** A critical step in using existing electronic health data from disparate healthcare organization with different EHRs for research is harmonization with a common data model. We worked with each of the partners to ensure that their data could conform to the OMOP V4 CDM and that the data required for the study was available in some form before outputting data to the federated database. Data conforming to the OMOP CDM V4 can be using to operationalize observational CER studies.

**Implications for Policy, Delivery, or Practice:** Even though EHRs all use different backend databases, they can be harmonized to a CDM for research purposes. We recommend that the EHR industry move toward having a standard data model so that the initial harmonization step is less cumbersome.

National Patterns of Pediatric Bipolar Disorder and Treatment in Relation to Comorbid Behavioral Conditions
Mehmet Burcu, University of Maryland; Rajakannan Thiyagu, Pharmaceutical Health Services Research Department, University of Maryland; Julie M. Zito, Ph.D., Pharmaceutical Health Services Research Department, University of Maryland; Daniel J. Safer, M.D., Departments of Psychiatry and Pediatrics, Johns Hopkins University
**Presenter:** Mehmet Burcu, M.S., Graduate Student, Pharmaceutical Health Services Research Department, University of Maryland, mburc001@umaryland.edu

**Research Objective:** Pediatric bipolar disorder (PBD) has drawn attention in recent years from published studies showing that the rate of clinician-reported diagnosis of bipolar disorder has increased dramatically among youth in the United States (1994 – 2003), with a corresponding increase in medications to treat it. Despite the high visibility of this topic, information is lacking on more recent pediatric bipolar visit patterns in terms of demographic and clinical characteristics, psychotropic medication use and the impact of comorbid conditions on its treatment. The objective of this study was to identify these patterns and, specifically, to assess the impact of comorbid behavior disorders on visit rates and psychotropic medication treatment in a nationally representative sample of ambulatory youth visits.

**Study Design:** In a cross-sectional study, PBD visits and total youth visits were extracted, analyzed at the visit level and assessed with population-weighted bivariate and multivariable methods. The main dependent variables are PBD visit rate and psychotropic medication use [total psychotropics (all 7 classes) and separately, antipsychotics, antidepressants, anticonvulsant-mood stabilizers, stimulants, lithium, anxiolytics and hypnotics, and alpha-agonists]. Other covariates included gender, age group (2-9; 10-14; 15-19), race/ethnicity, physician practice type, payment type, region of visit and comorbid psychiatric conditions.

**Population Studied:** The analysis draws on a nationally representative sample of pediatric outpatient visits to office-based physicians between 2003 and 2010, as captured in the National Ambulatory Medical Care Survey (NAMCS). There were 32,941 pediatric visits, of which 318 included the diagnosis of pediatric bipolar disorder.

**Principal Findings:** PBD visits were compared with total pediatric visits: Administrative differences showed that more PBD visits involved treatment by psychiatrists than by other practitioners (p=0.0001) and were privately insured (p=0.018). More PBD visits were associated with comorbid behavior disorders (73.22%) than without behavioral disorders. The rank order of psychotropic medication use was: antipsychotics (64.26%) followed by anticonvulsant-mood stabilizers (45.02%), stimulants (38.63%) and antidepressants (34.22%). Most of the PBD visits had prescribed antipsychotics in combination with one or more other drug classes (68.84%). When PBD visits were stratified by comorbid behavioral disorders, males, 2-9 year-olds, and those with non-private insurance had greater proportions of visits with comorbid behavioral disorders. While antidepressants were less common in PBD visits with comorbid behavioral disorders, stimulants and anxiolytics/hypnotics were significantly more commonly prescribed. The adjusted odds of PBD youth having a comorbid behavioral disorder compared with their non-behavioral counterparts was 3.7 (95% CI=2.1, 6.3) times greater during 2007-2010 compared with 2003-2006; 5.6 (95% CI=2.8, 11.1) times greater in 2-9 year olds compared with older youth; and 2.9 (95% CI=1.7, 5.0) times greater among males compared with females.

**Conclusions:** Behavioral conditions accompanying bipolar disorder are prominent in youth and recent patterns reflect complex medication regimens that warrant benefit-risk assessment in community populations.

**Implications for Policy, Delivery, or Practice:** Studies to evaluate evidence for the effectiveness, safety and tolerability of psychotropic combinations, particularly antipsychotics with stimulants, in the community treatment of pediatric bipolar disorder is warranted.

**Concordance with Antibiotic Treatment Guidelines: Variations by Community Health Center and Private Physician Practices**

Craig Burns, The University of Oklahoma; Michael J. Miller, The University of Oklahoma College of Pharmacy; Donald L. Harrison, The University of Oklahoma College of Pharmacy; Michael J. Smith, The University of Oklahoma College of Pharmacy; Ari K. Mwachofi, The University of Oklahoma College of Public Health; Ann E. Lloyd, The University of Oklahoma College of Pharmacy

**Presenter:** Craig Burns, MS, College of Pharmacy, The University of Oklahoma, Craig-Burns@ouhsc.edu
Research Objective: Antibiotic-resistant infections are estimated to cost over 20 billion dollars annually in the US. In 2004, guidelines for the diagnosis and management of acute otitis media [AOM] in children were established to promote antibiotic stewardship. While prior research has demonstrated suboptimal adherence to treatment guidelines, little is known about whether physician practice setting is associated with guideline concordance. In particular, this study evaluated variations in the treatment of children, with AOM, seen at a Private Physician Practice [PPP] or a Community Health Center [CHC].

Study Design: This cross-sectional study utilized data from the National Ambulatory Medical Care Survey [NAMCS], a national survey of the use of ambulatory medical care services. Physician visits for patients between the ages of 6-months and 12 years old, diagnosed with AOM only, between 2006 and 2010, were included. Visits from patients with comorbid conditions that might involve the prescription of an antibiotic were excluded. A two-level practice setting variable, [Private Practice vs. Community Health Center], was created and served as the independent variable of interest. Consistent with the 2004 AOM treatment guideline, an indicator variable representing guideline concordance was created using age, febrile status, and type of antibiotic prescribed. In addition, cases were classified as guideline discordant if the temperature was not taken. Patient characteristics and antibiotic prescribing were summarized using descriptive statistics for each setting. Bivariable associations between practice setting and guideline concordance were evaluated using the design-based F statistic. A multivariable logistic regression model was used to evaluate the association between practice setting and guideline concordance while controlling for the covariates: sex; race/ethnicity; payment method; and geographic region. All analyses were performed using complex survey commands, which included weighting and sampling design variables to enable accurate population point estimates and standard errors.

Population Studied: 897 office visits for children aged 6-months to 12 years, diagnosed with AOM from 2006-2010, were identified. Of these, 802 visits occurred at PPPs and 95 occurred at CHCs. The sample was balanced for age, sex, and febrile status; however, significant differences were observed for race/ethnicity, payment method, and geographic region. More than seventy-five percent of patients received an antibiotic prescription, regardless of practice site.

Principal Findings: The percentages of guideline concordant visits were not significantly different between the PPP and CHC settings (27.44 vs. 24.73, p=0.7788) in bivariable analysis. When adjusted for sex, race/ethnicity, payment method, and geographic region, children seen at CHCs were equally likely to receive guideline concordant care compared to their peers at PPPs [AOR=0.69, p=0.421]. The observed relationship did not change regardless of whether the patient’s temperature was taken.

Conclusions: Although patients seen at CHCs were equally likely to receive guideline concordant care, overall concordance with AOM treatment guidelines is suboptimal, regardless of practice site.

Implications for Policy, Delivery, or Practice: This initial, descriptive study highlights the need for further research into the factors associated with guideline discordant care.

The Agency for Healthcare Research and Quality Health Care Innovations Exchange: Sharing Innovative Solutions to Improve Quality and Reduce Disparities

Deborah Carpenter, Westat, Inc.; Judi Consalvo, Agency for Healthcare Research and Quality; Veronica Nieva, Westat; Susan Hassell, Westat

Presenter: Deborah Carpenter, RN, MSN, CPHQ, PMP, Senior Study Director, Westat, Inc.; deborahcarpenter@westat.com

Research Objective: Every day, health care professionals find novel ways of improving health care delivery and reducing disparities. However, the diffusion of innovative ideas and policies is slow and rarely reaches beyond institutional walls or across health care settings. As a result, providers often are not able to benefit from effective, already available solutions to improve care, enhance patient safety, and reduce disparities. The AHRQ Health Care Innovations Exchange addresses this challenge by providing readily accessible, evidence-based information to the health care community, with an aim to increase awareness, implementation, and uptake of innovative health care delivery strategies and policies in order to improve health care quality and reduce disparities. The target audience includes health practitioners and
administrators, quality improvement professionals, researchers, and policymakers. **Study Design:** To achieve this aim, the Innovations Exchange provides a rich, publicly available Web site (www.innovations.ahrq.gov) that offers free access to searchable descriptions of health care service delivery and policy innovations, in addition to tools to help users measure and improve health care quality. Health care professionals can learn about the processes of innovation, implementation, and spread through articles, expert commentaries, and adoption guides. Interactive learning and networking events include Web seminars, discussion forums, online chats, and in-person meetings. The Innovations Exchange encourages the exchange of information about creative strategies and policies by connecting innovators and potential adopters. Users can exchange ideas, experiences, and information about specific topics; learn from their peers about what works and what doesn’t; and collaborate to resolve common problems. Innovation profiles also provide information on contextual factors surrounding adoption and implementation successes to foster the spread of innovations across organizations and settings.

**Population Studied:** N/A

**Principal Findings:** N/A

**Conclusions:** Since its launch in 2008, the Innovations Exchange collection has grown to include over 750 innovations and 1,500 QualityTools. It is one of the federal government’s most highly rated Web sites, with more than 42,000 subscribers and 35,000 average monthly visits. Over 4,000 clinicians, health administrators, and researchers have participated in various Innovations Exchange events. Innovators and adopters report that the Innovations Exchange enhances their efforts to improve health care and ensure patient safety.

**Implications for Policy, Delivery, or Practice:**

As a national resource, the Innovations Exchange continues to evolve to capture new developments in a rapidly changing health care environment, providing information about cutting edge practices and policies at the forefront of health care. In 2012 the program expanded its scope beyond health care service delivery to include innovative health care policies at the organizational, system, and state levels that have important implications for the delivery of patient care. These profiles describe creative implementations of new or altered governmental or private initiatives that aim to improve health care quality by changing behavior through regulatory mechanisms, incentives, or other means to ensure accountability. As part of this effort, the program developed a comprehensive set of inclusion criteria that characterize the notion of health care policy innovation, establishing a precedent that enables the sharing of knowledge about innovative health care polices on a national level.

The Associations among Physician Volume, Processes, and Outcomes of Care for Acute Myocardial Infarction and Stroke

Guann-Ming Chang, Cardinal Tien Hospital; Yu-Chi Tung, Ph.D., National Taiwan University

**Presenter:** Guann-Ming Chang, MD., MS., Attending Physician, Department of Family Medicine, Cardinal Tien Hospital, ruri2elf@yahoo.com.tw

**Research Objective:** Volume-outcome relations have been found for acute myocardial infarction and stroke; however, the associations between physician volume and processes of care remain unclear. It is also not known whether processes of care are mediators of volume-outcome relations; that is, whether the mechanisms underlying volume-outcome relations are through processes of care.

**Study Design:** We used nationwide population-based data from Taiwan’s National Health Insurance Research Database. Using multilevel logistic regression models for each condition, we estimated the change in the odds of use of processes of care associated with an increase of 100 patients in the previous annual physician volume. Analyses were adjusted for patient, physician, and hospital characteristics. Multilevel mediational models were used to examine the mediating effects of processes of care on the association between physician volume and 30-day mortality.

**Population Studied:** All beneficiaries who were hospitalized in 2008 in acute care hospitals for acute myocardial infarction or ischemic stroke.

**Principal Findings:** There were 10,436 hospitalizations for acute myocardial infarction and 28,380 for ischemic stroke. For acute myocardial infarction, higher physician volume was associated with increased use of aspirin, angiotensin-converting enzyme inhibitor/angiotensin-receptor blocker, beta blocker, and percutaneous coronary intervention
therapy. For ischemic stroke, higher physician volume was associated with increased use of physiotherapy and occupational therapy assessment. The processes of care partly explain the associations between physician volume and mortality for acute myocardial infarction and ischemic stroke.

**Conclusions:** Admission to higher-volume physicians was associated with an increase in the use of certain processes of care, which was in turn related to a reduction in mortality for acute myocardial infarction and stroke.

**Implications for Policy, Delivery, or Practice:** The current findings may provide good evidence supporting centralization or regionalization to treat patients or train physicians or may contribute to the formation of health policy, for instance by introducing centralization or steering patients toward physicians who are more compliant with processes of care.

**Variations in the Use of Cardiovascular Disease Preventive Services among Hispanic and Asian Americans in California**

Eva Chang, Johns Hopkins Bloomberg School of Public Health; Ernest Moy, Agency for Healthcare Research and Quality

**Presenters:** Eva Chang, Ph.D. Candidate, Johns Hopkins Bloomberg School of Public Health, echang@jhsph.edu

**Research Objective:** Cardiovascular diseases (CVD) are among the leading causes of death for Hispanic American (HA) and Asian American (AA) adults, and several campaigns, like Million Hearts, were implemented to reduce CVD risk by using effective, clinical preventive services. Understanding of current levels and factors associate with primary and secondary preventive services use for CVD among HA and AA ethnicities is needed.

**Study Design:** Data were aggregated from the 2005, 2007, and 2009 California Health Interview Survey, when possible. Logistic regression was used to assess primary prevention (aspirin use at least 3 times/week, cholesterol screening in the last five years) and secondary prevention (treatment for high blood pressure (BP)). Three sets of models were run, including all race/ethnicities, non-Hispanic AAs only (Chinese, Filipino, Japanese, Korean, Vietnamese, Other Asian), and HAs only (Mexican, Puerto Rican, Central American, South American, Other Hispanic), with non-Hispanic Whites (NHWs), Chinese, and Mexicans, respectively, as reference categories. Models were survey-weighted and adjusted for English proficiency, insurance, education, citizenship, duration in US, age, gender, poverty level, health status, and survey year. Models for BP treatment also adjusted for diagnosis of any heart disease. All reported odds ratios had a p-value less than 0.05.

**Population Studied:** The sample used to assess primary prevention included 1. males between 45-79 years and females between 55-79 years for aspirin use (2005, n=18,726), and 2. all adults 18 years or older for cholesterol screenings (2005, n=43,020). The sample used to assess secondary prevention (BP treatment) included all adults 18 years or older with high BP (all years, n=47,992).

**Principal Findings:** Percentages of regular aspirin use, cholesterol screening in the last 5 years and treatment for high BP were 34.9, 86.7, 73.2 for NHWs, 25.4, 84.4, 57.9 for HAs, and 23.0, 83.2, 77.1 for AAs, respectively, with significant within subgroup heterogeneity. Compared to NHWs, Mexicans and Central Americans had 53-88 percent increased odds of cholesterol screening, Mexicans had 19% decreased odds of aspirin use, and HAs had no significant differences in BP treatment. Chinese, Japanese, and Koreans had 38-57 percent decreased odds of cholesterol screening, Chinese and Japanese had 50-57 percent decreased odds of aspirin use, while Chinese, Filipino, and Vietnamese had 69-111 percent increased odds of BP treatment compared to NHWs. Compared to Chinese, Japanese had decreased odds of cholesterol screening (OR=0.52) while Vietnamese had increased odds (OR=1.65). Filipinos (OR=1.9) and Other Asians (OR= 2.21) had increased odds of aspirin use. No significant differences were observed in BP treatment among AA ethnicities. No significant differences in prevention were observed among HA ethnicities.

**Conclusions:** Compared to NHWs, AAs had worse primary prevention service use but better secondary prevention service use; HAs had mixed use of primary prevention services and were similar in secondary preventive service use. Heterogeneity was found in primary prevention use among AAs. No differences were found among HAs, but ethnicity classifications were limited by sample sizes.
Implications for Policy, Delivery, or Practice: Use of recommended CVD preventive services varies by race/ethnicity and service type. Policies and interventions for AAs should target primary preventive services while those for HAs should focus on some primary preventive services.

Variations in Cardiovascular Disease Risk among Hispanic and Asian Americans in California
Eva Chang, Johns Hopkins Bloomberg School of Public Health; Ernest Moy, Agency for Healthcare Research and Quality

Presenter: Eva Chang, Ph.d. Candidate, Johns Hopkins Bloomberg School of Public Health, echang@jhsph.edu

Research Objective: Cardiovascular diseases (CVD) are among the top leading causes of death for Hispanic American (HA) and Asian American (AA) adults, with distinct heterogeneity found within the ethnic subgroups. However, few studies have examined variations in cardiovascular health among Hispanic and Asian Americans ethnicities.

Study Design: Data were aggregated from the 2005, 2007, and 2009 California Health Interview Survey. Logistic regression analyses were used to assess the odds of having 1, 2, or 3 or more CVD risk factors. Possible CVD risk factors included high blood pressure, diabetes, obesity, current smoking, and no moderate/hard exercise within the past 7 days. Three sets of models were run, including all race/ethnicities, non-Hispanic AAs only, and HAs only, with non-Hispanic Whites (NHWs), Chinese, and Mexicans, respectively, as reference groups. Models were survey-weighted and adjusted for English proficiency, insurance, education, citizenship, duration in US, age, gender, poverty level, health status, and survey year. All reported odds ratios had a p-value less than 0.05.

Population Studied: The total sample included all adults (18 years and older) sampled in the 3 years, representing over 80 million individuals from California. The sample included 92,189 NHW, 13,080 non-Hispanic AAs (3,349 Chinese, 1,648 Filipinos, 1,177 Japanese, 2,208 Koreans, 2,394 Vietnamese, 2,304 Other Asians), and 25,420 HAs (19,585 Mexicans, 394 Puerto Ricans, 1,080 Salvadorans, 1,090 Other Central Americans, 971 Latino Europeans, 801 South Americans, 1,499 Other Hispanics).

Principal Findings: Percentages of having 1, 2, and 3 or more CVD risk factors were 34.0, 17.7, 8.2 for NHWs, 35.6, 19.2, 9.0 for HAs, and 39.0, 14.2, 4.5 for AAs, respectively. Significant within subgroup heterogeneity was observed. Compared to NHWs, Chinese, Filipinos, and Koreans had 26-33 percent increased odds of having 1 CVD risk factor while Other Hispanics had 19 percent decreased odds. Mexicans, Other Hispanics, and Filipinos had 13-28 percent increased odds of having 2 CVD risk factors compared to NHWs while Chinese and Other Asians had 20 percent decreased odds. Chinese, Vietnamese, and Other Asians all had decreased odds of having 3 or more CVD risk factors compared to NHWs. Among AAs, Vietnamese had lower odds of having 1 CVD risk factor compared to Chinese (OR=0.69), but Filipinos and Japanese had 62-76 percent increased odds of having 2 risk factors and Filipinos, Koreans, and Other Asians had significantly increased odds of having 3 or more risk factors. Among HAs, no significant differences were observed by subgroup. For both HAs and AAs, odds of having 3 or more risk factors were reduced significantly among immigrants (15 or more years in the US).

Conclusions: This study observed distinct heterogeneity in CVD risk factors among AAs compared to NHWs and within AA ethnicities in California. While fewer differences were observed among HAs, ethnicity classifications were limited by sample sizes.

Implications for Policy, Delivery, or Practice: Policies and interventions that target CVD risk among AAs should focus on specific ethnicities while programs for HAs may need to focus on other barriers to health. Survey data collection should increase efforts to oversample among subgroups, especially among HAs, for tracking and understanding variations in CVD risk among minority groups.

The Relationship between Nurse Staffing and Unit-acquired Pressure Ulcers: Which Nurse Staffing Measures Matter?
Jisun Choi, University of Kansas School of Nursing; Boyle, D. K., University of Kansas School of Nursing
Research Objective: A large body of literature has demonstrated that higher nurse staffing is significantly related to better patient outcomes. In these studies, a variety of nurse staffing measures have been used, including administrative data and RN self-report measures. Yet, little has been studied regarding which specific measures of nurse staffing have the strongest relationship with patient outcomes. Our study, therefore, examined the correlations among selected nurse staffing measures and compared the relationship between unit-level nurse staffing and unit-acquired pressure ulcers (UAPUs) on six types of acute care hospital units. Staffing measures included administratively derived nursing hours per patient day (HPPD), registered nurse (RN) skill mix, RN-reported number of patients assigned, and RN-reported perception of staffing adequacy.

Study Design: A descriptive correlational design was used to conduct a secondary analysis of 2011 linked data from two sources: the National Database of Nursing Quality Indicators® (NDNQI®) and the NDNQI RN survey. Random-intercept logistic regression analyses were performed to examine the relationship between nurse staffing and UAPU while accounting for unit and hospital characteristics for each of nurse staffing measures.

Population Studied: The final analytical sample included 2,346 units within 411 NDNQI member hospitals in the United States that reported data on nurse staffing and patient pressure ulcers as well as participated in the RN survey. Included unit types were critical care, step-down, medical, surgical, combined medical-surgical, and rehabilitation units.

Principal Findings: The RN-reported number of patients and HPPD were significantly correlated ($r = .80$). RN perception of staffing adequacy and HPPD were also significantly correlated ($r = .23$). Controlling for unit (RN education level and RN unit tenure) and hospital (bed size, teaching status, and case mix index) characteristics, RN perception of staffing adequacy and RN skill mix were significantly related to UAPU rates. Lower UAPU rates was related to higher RN perception of staffing adequacy ($OR = .77$) and a higher percentage of nursing hours provided by RNs (RN skill mix, $OR = .99$). No significant relationship of other nurse staffing measures (HPPD and RN-reported number of patients) to UAPU rates was found.

Conclusions: Findings showed that administratively derived HPPD and RN self-reported number of patients were highly correlated, whereas other administrative and perceptual measures of nurse staffing were not highly correlated. Also, the relationship between nurse staffing and UAPUs were found to be inconsistent by the selection of nurse staffing measures. These measures of nurse staffing may capture different aspects of nurse staffing on the nursing unit.

Implications for Policy, Delivery, or Practice: Researchers should select nurse staffing measures based on their study purpose or conceptual model. In addition, our findings indicated that RN perception of staffing adequacy was the strongest predictor of UAPUs. Nurse administrators and managers should evaluate not only HPPD, but also nurses’ perception of staffing adequacy to improve patient outcomes.

The Role of Clinical Information in Dermatopathology

Nneka Comfere, Mayo Clinic; Margot S. Peters MD, Mayo Clinic, Rochester, Minnesota; Jon C. Tilburt MD, Mayo Clinic, Rochester, Minnesota

Presenter: Nneka Comfere, M.D., Physician, Dermatology and Dermatopathology, Mayo Clinic, comfere.nneka@mayo.edu

Research Objective: Characterization of self-reported concerns and challenges of pathologists in the diagnostic testing handoff process for skin biopsy.

Study Design: Survey

Population Studied: Membership of the American Society of Dermatopathology

Principal Findings: Survey response rate was 33% (367/1103). 70% of respondents were male and 30% were female. 61% (224/367) had been in practice for greater than 10 years. 44% (162/367) of respondents reported spending more than 80% of their pathology practice interpreting skin specimens and 37% (136/365) signed out an average of less than 50 specimens per day. The majority of respondents (78%;258/331) noted that their primary role as a
The most common mode of communication utilized by requesting clinicians to convey clinical information for skin biopsy specimens included paper/electronic requisition forms (87%; 285/331), followed by telephone (7%; 24/331) and face-face (4%; 12/331) communication. However, most respondents reported being either somewhat or very dissatisfied with the paper/electronic requisition forms as compared to telephone (7%) or face-face communication (4%). 55% (189/341) respondents noted that the quality of clinical information supplied by their requesting clinicians were excellent, very good or good and 97% (331/340) noted that the dermatologic experience of the requesting clinician was crucial to the quality of clinical information provided. Key clinical elements identified by most respondents as necessary for rendering accurate histopathologic interpretations included dermoscopic features, clinical photos, ABCDE criteria, results of relevant laboratory tests, clinical symptoms, lesion morphology, duration of lesions, partial or complete sampling, known clinical diagnoses, previous dermatopathology diagnoses, previous and current treatments and clinical differential diagnoses. 63-84% of respondents noted that the quality, completeness and clarity of the clinical information provided by the requesting clinician had a large impact on their diagnostic confidence, diagnostic accuracy, specificity of diagnosis, speed of diagnosis, need for additional communication with clinician, need for additional histopathologic studies and ability to provide meaningful clinical guidance within the pathology report.

Conclusions: Pathology members of the American Society of Dermatopathology highlighted the importance of the quality and completeness of clinical information supplied by the requesting clinician to diagnostic accuracy, relevance of the pathology interpretation, pathology service utilization and pathologist efficiency. They also cited significant dissatisfaction with the common mode of communicating clinical information - paper/electronic requisition forms and suggested some critical clinical elements necessary for accurate and relevant pathologic interpretation.

Implications for Policy, Delivery, or Practice: The common modes of communicating clinical information between the requesting clinician and pathologist fail to consistently include salient diagnostic information important for accurate dermatopathologic interpretation. This likely greatly influences the quality of dermatopathologic interpretation and ultimately will also influence the quality and safety of patient care, health care utilization and costs. This survey highlights significant knowledge gaps in optimal modes of communicating pertinent clinical information and mechanisms to support consistent and efficient transfer of such information between the requesting clinician and the pathologist.

Concordance Between Self Reported Medication Use and Medicare Part D Claims

Elizabeth Cook, University of Iowa; Kathleen M. Schneider, Buccaneer, A General Dynamics Company

Presenter: Elizabeth Cook, M.S., Research Specialist, College of Pharmacy, University of Iowa, elizabeth-cook@uiowa.edu

Research Objective: To examine the concordance between self-reported cardiovascular medications on arrival and claims-based measures of drug use at the time of admission to inpatient care for an acute myocardial infarction (AMI).

Study Design: The inpatient medical records for a sample of Medicare patients (n=730) who were hospitalized for AMI in 2007 or 2008 were abstracted and linked to Part D claims data. Abstracted on-arrival medications were compiled and patients were identified as statin, beta-blocker, and/or ACE/ARB users. Using Medicare Part D data, we then compared abstraction results to three different claims based measures of use of these medications. These included: 1) any prescription filled within the 90 days prior to admission, 2) estimated cabinet supply (pills on hand) based on the last fill prior to admission, and 3) estimated cabinet supply based on fill history for 6 months prior to admission. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated for all three measures, using abstraction measures as the gold standard.

Population Studied: 730 Medicare patients with fee-for service Part A and B, and the Part D
benefit who were hospitalized with AMI in 2007 or 2008.

**Principal Findings:** For statins, sensitivities for the three claims based measures ranged from 67-73%; specificities ranged from 83-87%. For beta blockers, sensitivities ranged from 72-80% and specificities ranged from 79-85%; for ACE/ARBs, sensitivities ranged from 70-80% and specificities ranged from 71-77%. The estimated cabinet supply based upon the last fill prior to admission was the least sensitive measure for all three types of drugs, while its specificity was between the other two claims based measures. Evidence of any fill in the 90 days prior to admission was the most sensitive for all three types of drugs and the least specific of all three measures; although this measure was more sensitive than specific for beta blockers and ACE/ARBs, the relationship was reversed for statins, and this measure also had the highest NPV for all three drugs. Estimated cabinet supply based on fill history for 6 months prior to admission consistently had the highest specificities, sensitivities that fell between the other two measures, and the highest PPVs across all three drugs.

**Conclusions:** When measuring use of statins or beta blockers, claims based measures that rely on either measure of estimated cabinet supply tend to be more specific than sensitive, while evidence of a fill in the past 90 days tends to be more sensitive. When measuring use of ACE/ARBs, sensitivity and specificity measures are similar regardless of the measure. Cabinet supply measures that use fill history over six months appear to offer the best tradeoff in terms of sensitivity and specificity.

**Implications for Policy, Delivery, or Practice:** Depending on study objectives and investigator requirements for accuracy, Medicare claims-based measures of cardiovascular drug use appear to be reasonably concordant with self-reports.

**Children’s Safety Initiative-EMS: A Five-Part, Mixed-Methods Research Project**
Jeanne-Marie Guise, Oregon Health and Science University; Erika Cottrell, Oregon Health and Science University; Erika Barth Cottrell, Oregon Health and Science University; William Lambert, Oregon Health and Science University; Jonathan Jui, Oregon Health and Science University; Merlin Curry, Oregon Health and Science University; Kerth O'Brien, Oregon Health and Science University; Phillip Engle, Oregon Health and Science University; Garth Meckler, Oregon Health and Science University

**Presenter:** Erika Cottrell, Ph.D., M.P.P., Comparative Effectiveness K12 Scholar, Oregon Health and Science University, cottrele@ohsu.edu

**Research Objective:** Emergency Medical Services (EMS) professionals are charged with responding to a range of critical events including emergencies, natural disasters, and traumas. This type of care relies upon professionals who must make decisions under conditions of uncertainty and considerable time pressure. Errors are bound to occur and their consequences can be a matter of life and death. While the incidence of, and contributors to, adverse events in hospitals are well described, we know little about adverse events in the prehospital care environment, particularly in regard to children. The Children’s Safety Initiative-EMS was designed to increase our understanding of safety in the prehospital pediatric emergency setting. The overarching goal of this project is to describe the contributors to and underlying causes of pediatric safety events - which we have termed UNSEMs (Unintentional injury or consequence, Near miss, Suboptimal action, Error, Management complication) - and to identify opportunities for interventions that will ultimately improve EMS care for children. Attaining such a multi-faceted understanding requires a thorough investigation of existing patterns and contributors using a mix of methodological tools. This abstract describes the comprehensive and unique methodology of The Children’s Safety Initiative.

**Study Design:** The Children’s Safety Initiative-EMS has five main study components: focus groups, a 3-round national Delphi survey and expert advisory panel, prehospital chart review, an anonymous reporting system, and in situ simulations. Each component is necessary to fully understand the range of individual and systems contributors to the occurrence of safety events.

**Population Studied:** Participants include EMS providers (fire department, private ambulance, public ambulance, volunteer, and paid EMT’s as well as emergency department physicians and nurses), EMS program managers and EMS leaders.

**Principal Findings:** Focus groups (n=45) were conducted to identify the range of contributors to
safety events in the prehospital emergency care of children. These findings were used to develop a 3-round Delphi survey (n=722) to establish consensus on the most important contributors to safety events in a larger national sample. At the conclusion of the three-round Delphi survey, we engaged an expert advisory panel to provide input on our results and apprise us of ongoing interventions or trainings related to our findings. With the focus groups, Delphi survey, and expert advisory panel portions complete, we have identified the top five contributing domains to EMS-C safety events: assessment and decision-making, medication and equipment, training, EMS cultural norms, and scene characteristics.

**Conclusions:** Additional investigations and methodologies will broaden the foundation of knowledge gained through the focus groups, Delphi survey, and expert advisory panel. Chart review, the anonymous reporting system, and in situ simulation will further expand our knowledge of key ingredients that lead to safety events and provide insight to facilitate the development of interventions to improve the safety of children’s prehospital emergency care.

**Implications for Policy, Delivery, or Practice:** Utilizing a mix of methodological tools provides a unique and comprehensive understanding of the factors that contribute to safety of children’s prehospital emergency care that will enable the design of interventions to improve the delivery of care and the overall health of children.

**Assessing Two Year Readmission Risk in Small Children Hospitalized with Acute Respiratory Distress: A Retrospective Cohort Analysis Using Administrative Hospital Data**

Chris Craver, MedAssets; Kathy Belk, MedAssets, Inc.; Dr. Chris Blanchette, IMS Health and University of North Carolina at Charlotte

**Presenter:** Chris Craver, MA, Senior Director, Health Data Analytics, MedAssets, ccraver@medassets.com

**Research Objective:** The objective of this research is to conduct cohort feasibility analysis using hospital based administrative billing data to assess causes and long term readmission risk for children under the age hospitalized for acute respiratory distress.

**Study Design:** The study cohort consisted of children between one and two years of age who were hospitalized in 2009 for acute respiratory distress (ARD) in the MedAssets Health System Database. ARD was defined as bronchiolitis (ICD-9 466.1x), wheezing and cough (ICD-9 786.0x), or asthma (ICD-9 493.xx). Where possible the population was further classified based on the underlying cause of respiratory distress including RSV (ICD-9 079.6), rhinovirus (ICD-9 079.3), or influenza (ICD-9 487.1). The occurrence of pneumonia was identified as well. Patients were excluded from the cohort if they were hospitalized during a period three months prior to the reference hospital discharge. Finally, to insure consistency, hospital data were only included in the analysis if both inpatient and outpatient data were available for the entire study period (between October 2008 and December 2011). The primary independent variable was inpatient readmissions. Primary dependent variables included patient demographics (age/sex), visit characteristics (discharge status, admission source, admission type) and hospital service characteristics (bed size, location, teaching status, and urbanicity). Univariate statistical methods were used to describe the base population. A negative binomial generalized linear regression model was used to identify key predictors of readmission.

**Population Studied:** The base population consisted of 407 unique patients across 57 acute care hospitals.

**Principal Findings:** The patient population were predominately male (62.9%) and were admitted to hospitals with 300+ beds (75.0%) that were teaching facilities (75.3%). The primary type of admission for the reference hospitalization was emergent or urgent (64.0%). Asthma (51.1%) was by far the most common diagnosis for the study population’s first hospitalization. This was followed by pneumonia (37.3%), bronchiolitis (29.5%), wheezing (12.3%), and influenza (7.6%). Patients may have multiple respiratory diagnoses during their initial hospitalization.

During the study period the base population generated over 1600 (3.9 per patient) additional admissions which were distributed as 35% inpatient admissions and 65% outpatients visits. Of these subsequent admissions 795 could be classified as respiratory related by the primary diagnosis. After controlling for patient characteristics and hospital demographics only a prior hospitalization of asthma (1.56 additional
visits, p < .001) and type of admission of emergency (1.3 additional admissions, p < 0.05) in the reference hospitalization predicted readmission.

**Conclusions:** Young children hospitalized with acute respiratory illness tend to have recurring hospital visits throughout the first three to four years of their lives. In this study only an initial hospitalization for asthma was associated with significantly more hospital visits in the follow-up period. However, one limitation of administrative data is that patients cannot be tracked across facilities or care settings.

**Implications for Policy, Delivery, or Practice:**
This study demonstrates that it is possible to use administrate data to identify and track pediatric respiratory distress patients in an acute setting. Use of data of this type can provide directional if not concrete evidence of resource utilization patterns and treatment paths

**Funding Source(s):** No Funding
**Poster Session and Number:** C, #929

**Cost Effectiveness and Health Outcomes of Consumer Directed Long Term Care Services in Colorado**

Candle Dalton, Colorado Department of Health Care Policy and Financing; Sally Langston, Colorado Department of Health Care Policy and Financing; Aaron Neiderhiser, Colorado Department of Health Care Policy and Financing; Josh Winkler; Jed Ziegenhagen, Colorado Department of Health Care Policy and Financing

**Presenter:** Candie Dalton, Participant Directed Programs Specialist, Colorado Department of Health Care Policy and Financing, candie.dalton@state.co.us

**Research Objective:** Consumer Directed Attendant Support Services (CDASS) allows long term care recipients to manage their own services, caregivers, and the budget to pay for those services. Medicaid cost data shows that CDASS in Colorado is more costly than agency-based care; however, there is not a method to compare CDASS cost data to clients with similar levels of need who receive services from an agency-based model. In this study, the acuity level of CDASS clients is compared to client cohorts who receive agency-based care to evaluate cost effectiveness of service delivery and health outcomes.

**Study Design:** The study design utilizes a difference-in-difference approach with patient fixed effects to isolate the effect of the program on cost and health outcome metrics.

**Population Studied:** Adults age 18 years and older who receive long term care services through one of three Medicaid-funded Home and Community Based Services (HCBS) Waivers operated in Colorado that offer both agency-based care and CDASS. The study includes approximately twenty five thousand clients, as of June 2012, who have a physical disability, a diagnosis of a major mental illness, or who are elderly (ages 65 and older).

**Principal Findings:** Initial analysis shows the average per capita costs for clients directing their own services are greater than the average per capita cost for each of the three HCBS Waivers. Further analysis of the comparative control group reveals that when total Medicaid costs are combined for clients with similar acuity levels, the per capita cost of CDASS is no greater than the per capita cost of agency-based care. Health outcomes data reveals that critical incidents and adverse health outcomes that lead to emergency room visits, increased hospital admissions, and longer lengths of stay do not occur at a higher rate in CDASS than when care is managed by an agency. While this might be due, in part, to the controls implemented to limit clients with unstable or unpredictable health progression to participate in CDASS, it might also be due to clients being able to select and train their own caregivers.

**Conclusions:** The conclusion of the research demonstrates that consumer direction is a viable service delivery option to provide cost effective services to clients who require long term care while also maintaining or increasing positive health outcomes by reducing the number of critical incidents and hospital admissions.

**Implications for Policy, Delivery, or Practice:**
Evidence that CDASS is cost effective and does not increase adverse health outcomes has significant implications for policy, delivery, and practice. This evidence further supports the development and implementation of public policy to expand the opportunities for consumer direction and allow for a more fluid continuum of service delivery options from agency-based care to consumer directed care to include increased self-determination practices and person centered planning across the spectrum of long term care.

Challenges in Safely Managing the Pain in Living Liver Donors
Daniela Ladner, Northwestern University; Amna Daud, Northwestern University; Kathryn Waitzman, Northwestern University; Teri Strenski, Northwestern University; Mary Ann Simpson, Lahey Clinic; Robert Brown, Columbia University; Robert Fischer, Virginia Commonwealth University; Tija Berzins, , Donna Woods, Northwestern University

Presenter: Amna Daud, M.D., M.P.H., Clinical Research Associate, Northwestern University, a-duad@northwestern.edu

Research Objective: Living liver donation (LD) is a large surgery associated with pain. However, managing pain after LD is difficult, as opioid pharmacokinetics change after a large liver resection. Respiratory depression and perceived pain in LD have not previously been reported.

Study Design: Retrospective medical record review
Population Studied: Retrospective medical record review (years 2008-2010) of 23 LDs from four large LDLT centers was conducted by an RN reviewer. POD#0-7 pain scores (1-10 scale), pain medication, and incidence of respiratory depression requiring intervention were assessed.

Principal Findings: All LDs received IV opioids after LD. 56% received IV NSAIDS, 26% had an epidural. PO medications increased from 13% to 100% at discharge. LD had mean pain scores of 3.86, 4.52, 4.03, 3.74, 4.81, 4.41, 5.91, and 4.75 from POD #0-7, respectively; however pain scores ranged from 0-10 throughout POD#0-7. The highest reported mean pain scores occurred on POD#6 (5.1). Percentage of pain score assessments > 6 increased on POD#4 (34%), and were highest on POD#6 (48%). (Table). 5 LD (22%) suffered respiratory depression requiring higher level care (PACU, ICU), respiratory interventions (i.e. re-intubation), reversal agents, and adjustments in ordered pain medications.

Conclusions: LD experience significant pain after LD according to their subjective pain scores, despite extensive multifaceted pain regimens. Most pain is experienced as IV drugs are switched to PO regimen.

Implications for Policy, Delivery, or Practice: Despite close monitoring a significant portion of patients experience sequelae of over narcotization, presenting significant patient safety risk to LD. Pain management in LD needs to be improved to safely provide better pain control.

Safety Issues Identified by Proactive Liver Transplant Safety Debriefing
Daniela Ladner, Northwestern University; Amna Daud, Northwestern University; Tija Berzins, Northwestern University; Elizabeth Pomfret, Lahey Clinic; Robert Brown, Columbia University; Robert Fischer, Virginia Commonwealth University; Teri Strenski, Northwestern University; Lisa McElroy, Northwestern University; Donna Woods, Northwestern University

Presenter: Amna Daud, M.D., M.P.H., Clinical Research Associate, Northwestern University, a-duad@northwestern.edu

Research Objective: Transplantation and, in particular, living donor liver transplantation (LDLT), involves complex systems and process of care that are particularly susceptible to medical errors and preventable complications. In order to capture safety issues during LDLT procedures, a proactive, web-based clinician safety debriefing tool was developed and implemented at four Adult-to Adult Living Donor Liver Transplant (A2ALL) hospitals.

Study Design: All clinicians at four A2ALL centers who participated in LDLT procedures (Donor, Recipient) between Sept. 2010 and Oct. 2012 received a request to complete the web-based Safety Debriefing via email immediately after an LDLT surgery. The debriefing tool takes less than 3min to complete and provides clinicians with 24 prompts (e.g. “Access to Necessary Clinical Data”, “ABO Matching”) to elicit recollections of complications, near miss events and other safety issues that occurred. Reporters were identified, but answers were anonymous.

Principal Findings: 85 LDLT surgeries were debriefed. Responses were provided by surgical staff (32%), nursing staff (30%), anesthesiology staff (20%), and others (18%) (Perfusionists, Techs, Radiology team, Observers, etc.). 542 safety issues were reported. The most common reported categories were related to equipment
problems (15%), distractions (10%), inter-provider communication (8%), and timing of related procedures (6%).

Conclusions: Anonymous, short, online debriefings can successfully elicit rich information on the safety risk associated with LDLT surgery far beyond hospital wide reporting systems, which captured less than 5% of safety issues related to LDLT surgeries reported in the online debriefings. This is supporting evidence that to date safety risks associated with LDLT are poorly described and vastly underestimated.

Implications for Policy, Delivery, or Practice: The proactive comprehensive safety risk assessment of LDLT is crucial in the quest to perform safety LDLT surgeries for donors and recipients.

Blast Survey Takes Crack at Undergraduates' Health Information Technology Communication
Paul Frank Meole, BA, Eckerd College; Donna Ettel, Saint Petersburg College; George Leonard Ettel, III, University of South Florida; Donna Lee Ettel, Ph.D., Saint Petersburg College

Presenter: Donna Ettel, Ph.D., Adjunct Professor, Saint Petersburg College, ettel.donna@spcollege.edu

Research Objective: College students are faced with a unique set of challenges which may plausibly affect their healthcare decisions and there is minimal information in the literature about the nature and scope of HIT communication. The purpose of this study is to improve our understanding where college students go when they are ill, if insurance coverage is an issue, their trust in online sources and finally whether or not they are willing to communicate with their physicians electronically.

Study Design: The surveys were administered with links that were unique to the individual user to ensure privacy and allow the student to only submit the survey once. Analysis included descriptive statistics, and multi-variate analyses of variance to identify significant trends. This study was approved by IRB at Eckerd. The independent variables were student characteristics including age, race/ethnicity, grade level, and health insurance status. The dependent variables examined was student use of computers, search engines utilized and email utilization. Quality related variables include

where college students go when they are ill, if insurance coverage is an issue, their trust in online sources and finally whether or not they are willing to communicate with their physicians electronically.

Population Studied: The population at Eckerd College consisted of 2,310 of undergraduate students (43.8% males) with a racial make-up that was 61.5% white, 11.5% African-American, 16.8% Hispanic, 6.3% Asians and .52% other.

Principal Findings: A response rate of 15.97% (n= 292) was recorded. Of the respondents, 95.87% (n=280) reported that they had health insurance and 79.79% (n=233) had a primary care physician. Only 27.05% (n=79) of the respondents were male and 83.22% (n= 243) of respondents lived on campus. These data show that 90.75% (n= 265) do not use email to communicate with their physicians about medical related information, but 73.63% (n= 215) were willing to. If the respondents were ill, 58.56% (n= 171) reported they would first go to a health facility on campus and 42.47% (n= 124) would first go to their primary care physician; however 11.99% (n=35) would first go to an emergency room and 29.56% (n=86) would first go to a free clinic if they were ill.

Conclusions: These data clearly show that physicians appear to be an underutilized source of vital information that affects young adults in critical stages of their lives. These findings raise questions about how to ensure that college students have access to health information that is accurate and trustworthy. This study has several limitations. We studied students from a single, secular private college whose students do not necessarily reflect the population at large. Therefore, we are reluctant to infer that these findings are generalizable, although many of our results are similar to other reports.

Implications for Policy, Delivery, or Practice: This information is the first of its kind in the area of electronic healthcare surveys administered to college students and may assist policymakers and other key stakeholders in Florida—and nationally—in identifying, designing and implementing strategies to provide college students who are transitioning into adulthood access to appropriate healthcare information, including the role of physicians

Survivorship Care Planning among Cancer Survivors in the United States
Albert Farias, University of Washington; Steven Zeliadt, PhD, University of Washington, Dept. Health Services; Department of Veterans Affairs Puget Sound Health Care System

Presenter: Albert Farias, MPH, PhDc, Graduate Researcher, Health Services, University of Washington, afarias@uw.edu

Research Objective: To describe how frequently cancer survivors are provided with a written survivorship plan and given advice about where to receive follow up care following initial treatment.

Study Design: The study design is cross sectional. We used data from the 2010 cancer control supplement on cancer survivorship from the National Health Interview Survey for 593 breast, cervical, ovarian, prostate, and colon cancer survivors who were within 10 years of diagnosis. The NHIS annual household survey is a representative sample of non institutionalized, civilian household population of the United States. We applied survey sampling weights in order to make estimates about the entire US population. Covariates included sex, age, educational attainment, marital status, employment status, race and ethnicity, body mass index, and number of comorbidities. Logistic regression was used to identify factors associated with the likelihood of receiving follow up advice.

Population Studied: Our sample includes cancer survivors or those individuals who reported ever being told by a doctor that they had colon, prostate, lung, cervical, ovarian or breast cancer. We restricted our analysis to individuals over the age of 18 as the cancer survivor supplement was only given to adults. We further restricted the study sample to include individuals who are within 10 years of a cancer diagnosis.

Principal Findings: Approximately 80 percent of US cancer survivors received advice on where to go for follow up cancer care and 39 percent received written documentation of their cancer treatment. US cancer survivors who have survived from 5 to 10 years from the time of survey assessment were significantly less likely to receive advice about where to go for follow up cancer care compared to those who were diagnosed less than 1 year from the time of survey assessment, OR 0.51, 95 percent CI 0.27 to 0.96. Survivors who received written documentation of their cancer treatment were significantly more likely to have received advice about where to go for follow-up cancer care, OR 2.08, 95 percent CI 1.21 to 3.59. Lung cancer survivors were significantly less likely to receive written documentation of their cancer treatment compared to breast cancer survivors, OR 0.31, 95 percent CI 0.11 to 0.93, while colon cancer survivors were significantly more likely, OR 2.85, 95 percent CI 1.46 to 5.57.

Conclusions: A great majority of cancer survivors receive advice about where to go for follow up care from a physician or nurse, however there are differences that depend on the time since cancer diagnosis. Even fewer patients receive written documentation of cancer treatment and differences exist by cancer type.

Implications for Policy, Delivery, or Practice: As cancer survivorship increases the goal should be to have both written documentation and advice on where to receive care for all cancer survivors.

Poster Session and Number: C, #934

Association between Veteran Status and Diabetes Prevalence
Joseph Finkelstein, Johns Hopkins University School of Medicine

Presenter: Joseph Finkelstein, MD, PhD, Associate Professor of Medicine, Gerontology and Geriatric Medicine, Johns Hopkins University School of Medicine, jfinkel9@jhu.edu

Research Objective: The growing prevalence of diabetes in the US adult population represents a serious public health challenge. High diabetes prevalence results in substantial health care expenditures. A better understanding of risk factors for development of diabetes in adults may contribute to diabetes prevention efforts. Currently, it is unclear whether veteran status can be considered as a risk factor for diabetes. The goal of this project was to assess the association between veteran status and risk of developing diabetes.

Study Design: The Integrated Health Interview Series (IHIS) is a harmonized dataset for the U.S. National Health Interview Survey (NHIS). Using the IHIS 1997-2010 dataset, population-based prevalence of diabetes among veterans was compared to non-veterans, and further stratified by gender. Veteran status was defined as a positive answer to the question, "Have you ever been honorably discharged from active
duty in the U.S. Army, Navy, Air Force, Marine Crops, or Coast Guard?" Diagnosis of diabetes was based on self-report. Regression models were performed to evaluate the association between veteran status and risk for diabetes. In the gender-stratified analysis adjustment was made for socio-demographic factors and health behaviors. Sampling weights that adjust for the complex design of the NHIS were applied in all analyses presented. Statistical analyses were performed using SAS version 9.0. **Population Studied:** US National Health Interview Survey (NHIS) **Principal Findings:** From 1997 to 2010, overall 12.1% of veterans reported to have diabetes compared to 6.7% of non-veteran civilians (Rao-Scott chi square, p<0.0001). Among men, 12.6% of veterans and 5.8% of non-veteran civilians had diabetes (Rao-Scott chi square, p<.0001). For females, prevalence of diabetes (6.0%) was lower in veterans than non-veteran civilians (7.3%) with statistical significance (p<0.05). A regression model adjusting for age, race, education, poverty level, marital status, body mass index, alcohol consumption, smoking and exercise showed that male veterans were 1.4 times (95% CI 1.3-1.5) more likely to have diabetes than non-veteran civilians. For females, veterans had 6% (95% CI: 0.8-1.1) less risk for diabetes than civilians but with no statistical significance. **Conclusions:** Overall, the prevalence of diabetes was higher in male veterans as compared with non-veteran civilians. This association remained significant after adjusting for socio-demographic and health behavior factors. **Implications for Policy, Delivery, or Practice:** Since male veterans have higher risk of developing diabetes, a systematic pre-diabetes screening may be warranted in this population. **Funding Source(s):** No Funding **Poster Session and Number:** C, #935 **Effect of Providing Community Based Services on Hospitalization Rates for High Utilization Sample** Nancy Flinn, Courage Center **Presenter:** Nancy Flinn, Ph.D., Director, Outcomes And Research, Public Affairs and Research, Courage Center, nancy.flinn@couragcenter.org **Research Objective:** Persons with physical disabilities and cognitive deficits are high utilizers of hospital and emergency department services. These individuals have difficulty managing their health in a variety of ways – they are more likely than the general population to delay or not received medical care due to cost (31.8% to 13.8%) and not get prescribed drugs due to cost (26.5% vs. 7.5%) (National Center for Health Statistics, 2011). In Minnesota, Independent Living Services (ILS) are low-cost, community based service available through Medicaid waivers for individuals who are at risk for nursing home placement. These services are not generally reviewed for their impact on health care costs. ILS provides client-centered care, with an additional focus on accessing appropriate services. Roughly 30% of clients entering Independent Living Skills are at high risk of homelessness, so common goals for the program are stable housing, along with access to medication, food, and transportation, and access to primary and specialty health care. These social determinants of health are critically important for these clients who have limited resources. **Study Design:** A pre/post cohort design was used to analyze this data. Using Minnesota Department of Human Services data accessed through our medical home, hospital days were tracked for individuals before and after enrollment in ILS, during periods when they were not enrolled in the medical home. Through an analysis of the hospital days for 23 medical home clients enrolled in Independent Living Skills, per member per month hospitalization rates were calculated. **Population Studied:** This sample was 61% male, 39% female; 59% had incomes below poverty, 32% lived within 200% of poverty, and 9% lived above 200% of poverty. All clients in this sample were working age adults. The diagnostic groups served by these clients was 44% acquired brain injury, 21% other neurological conditions, 13% spinal cord injury, 13% cerebral palsy, and 9% musculoskeletal condition. All clients were on Medicaid, with 61% dually eligible for Medicaid and Medicare, and 39% for Medicaid only. **Principal Findings:** In this high utilization population, the average hospitalization rate was .70 days per member per month prior to enrollment in Independent Living Skills Services. After enrollment in ILS, the hospitalization rate dropped to .39 days per member per month. **Conclusions:** Low-cost community based services are a viable addition to a coordinated, comprehensive medical home as a cost-
effective method for meeting the triple aim. ILS can help clients be healthier and avoid hospitalization through addressing social determinants of health, such as housing, food, medicine, and medical care.

**Implications for Policy, Delivery, or Practice:** As health care costs continue to rise, finding effective solutions for addressing the health needs of expensive and medically complex populations is needed. The success of programs such as Independent Living Skills should change the debate to recognize the value of community-based services. This model is a low cost intervention to improve the health of individuals through effectively addressing the social determinants of health.

**Identifying Urban-Rural Health Disparities**
Sheila Franco, CDC/NCHS; Deborah D. Ingram, CDC/NCHS

**Research Objective:** To explore urban-rural health disparities using the six-level urban-rural classification scheme developed by the National Center for Health Statistics (NCHS).

**Study Design:** NCHS developed a six-level urbanization scheme based on the metropolitan, micropolitan, or noncore county designations from the Office of Management and Budget and metropolitan population size cut points defined by the Department of Agriculture’s Rural Urban Continuum Codes. NCHS supplemented these sources by conducting a discriminant analysis and formulating classification rules to separate the large metro category (counties in metro areas with population of 1 million or more) into large central (“inner cities”) and large fringe (“suburbs”). This distinction among large metro counties is important because residents of suburban areas tend to fare substantially better on many health measures than residents of other urbanization levels. The scheme was applied to data from the 2008-2010 National Vital Statistics System and the 2009-2011 National Health Interview Survey to explore differences in selected health measures by urbanization level.

**Population Studied:** U.S. population, adults aged 18 and over.

**Principal Findings:** Substantial differences in health measures by urbanization level were found. For example, death rates from motor vehicle accidents progressively increase across the six urbanization levels, with the lowest rates in large central metropolitan counties and the highest rates in rural counties. The age-adjusted motor vehicle accident death rate was approximately three times higher in the most rural counties than in the most urban counties. Homicide rates also differed by urbanization, with the highest rates in large central metropolitan counties. Fair or poor health status was lowest among adults aged 18–64 years residing in large fringe metropolitan counties and highest among those in the most rural counties. The percentage of uninsured adults aged 18–64 was lowest among those residing in large fringe metropolitan counties compared to all other urbanization levels.

**Conclusions:** For many health measures, differences by urbanization level were found. Of special note are the findings that residents of large central (inner cities) and large fringe (suburbs) metropolitan counties differ in many health measures. These differences are often obscured in urban-rural analyses which use large metropolitan as one category.

**Implications for Policy, Delivery, or Practice:** This analysis reveals differences in health measures across the six urbanization levels and demonstrates the usefulness and importance of the NCHS taxonomy for health analysis.

**Poster Session and Number:** C, #937

**Health Insurance Coverage Gaps in Early Adulthood: Implications for Current Insurance and Care**
Tracy Garber, The Commonwealth Fund; Jennie Smith, The Commonwealth Fund

**Presenter:** Tracy Garber, MPH, Senior Policy Associate, Affordable Health Insurance, The Commonwealth Fund, tg@cmwf.org

**Research Objective:** In 2011, 13.2 million adults ages 19-29 were uninsured, down from 13.8 million in 2010. This reversal in a trend of increasing numbers of uninsured young adults is largely attributable to the Affordable Care Act’s provision allowing young adults to stay on their parent’s plan until age 26. Still, not all young adults have this option and subsequently experience gaps in coverage at key transition points such as leaving high school. This
analysis identifies characteristics of young adults likely to experience a gap in coverage in early adulthood. It examines their current health care experiences to inform potential policy solutions that will ensure access to affordable coverage and health care for all young adults.

**Study Design:** Data for this survey comes from the Commonwealth Fund Health Insurance Tracking Survey of Young Adults, 2011, a nationally representative online survey of young adults ages 19-29 conducted by Knowledge Networks between November 4 and 24, 2011. The survey sample was drawn from KnowledgePanel—a probability-based online panel that is representative of the U.S. population and includes cell phone only and low-income households typically difficult to reach using traditional telephone surveys and random digit dialing sampling. **Population Studied:** Young adults in the U.S. ages 19 - 29 (N=1,863). The analysis is restricted to those who had insurance some or all of the time in high school (N=1,494).

**Principal Findings:** An estimated 8.5 million young adults who had insurance at least some of the time during high school lost their insurance or experienced a gap in coverage after leaving high school (23%). Compared to those who did not experience a gap, this group was more likely to: be black or Hispanic (44% vs 21%), be low income (59% vs 29%), stop seeing a childhood doctor by age 19 (76% vs 46%), take two or more years to find a new regular doctor (29% vs 19%) or to report never find one (43% vs 26%). Young adults with a coverage gap after high school had higher odds of being uninsured in the past year (OR 5.97 p=0.000), and lower odds of having a regular source of care (OR 0.54 p=0.005).

**Conclusions:** Young adults with a disruption in insurance coverage at the start of adulthood were poorer and more likely to be minorities than those who did not have a gap after high school. A gap in coverage at early adulthood is also related to a tenuous connection to insurance coverage and a regular doctor in the future.

**Implications for Policy, Delivery, or Practice:** The new state health insurance exchanges have the potential to close coverage gaps some young adults experience. The exchanges will provide a place for them to purchase coverage if they cannot join a parent’s plan or do not have an offer of affordable employer coverage, and will determine eligibility for public programs and premium subsidies. As open enrollment approaches in October 2013 states must undertake strategic public outreach to educate young adults about the exchanges. States should structure their exchanges so that enrollment and movement between plans do not interrupt coverage.

**Funding Source(s):** CWF

**Proton Pump Inhibitor Prescriptions and Agreement in Diagnoses between Otolaryngologists and Gastroenterologists**

**Research Objective:** Otolaryngologists (ENT) often prescribe proton pump inhibitors (PPIs) for symptoms associated with laryngopharyngeal reflux (LPR) and gastroesophageal reflux disease (GERD). Variations in diagnosis and management of reflux symptoms between ENT and gastroenterologists (GI) is unknown. The aims of this study were to determine 1) PPI prescriptions, diagnoses, and testing in patients seen by ENT and 2) Compare agreement in diagnoses, PPI prescriptions, and testing in patients also seen by GI.

**Study Design:** Retrospective cohort study at Northwestern University.

**Population Studied:** Patients aged 18-90 seen in the Northwestern ENT practice and provided a new PPI prescription from 2005-2011 were included. PPI prescription, diagnoses, and procedure data were obtained from the electronic database. Chart review was performed on patients with both an ENT and GI evaluation to determine differences in diagnoses, PPI prescriptions, and diagnostic testing. Descriptive statistics and tests for agreement in diagnoses were performed.

**Presenter:** Andrew Gawron, M.D., Ph.D., Fellow, Division of Gastroenterology/Institute for Healthcare Studies, Northwestern University Fernbeg School of Medicine, agawron@fsm.northwestern.edu
**Principal Findings:** 2,427 patients were provided a new PPI prescription by ENT between 2005 and 2011. Patients were 52.2 yrs of age (sd 15.4) and predominantly female (56.4%), white (58.1%), and non-Hispanic (65.6%). Esomeprazole accounted for the greatest number of prescriptions (722, 29.8%), followed by omeprazole (582, 24.0%). Of patients given a PPI prescription, the primary, secondary, or tertiary ENT diagnosis was reflux (GERD, LPR) in 1,018 patients (41.9%). Other diagnoses were highly variable and included hoarseness (11.2%), cough (6.1%), and sleep apnea (4.9%). Diagnostic laryngoscopy was performed in 672 encounters (27.7%). A total of 140 patients (5.8% of 2,427) also saw GI (90 after ENT, 48 prior to ENT, and 2 on the same day). Of these 140 patients, 94 (67.1%) were given a standard diagnosis of GERD by GI and 33 (23.6%) were documented to have extra-esophageal symptoms (e.g. sore throat, globus). GI and ENT agreed 55.7% of the time in a standard reflux diagnosis (kappa statistic = 0.08). GI diagnoses, including extra-esophageal symptoms, supported reflux in 81.4% of patients who were prescribed a PPI by ENT. GI and ENT prescribed the same PPI in 73 patients (59.8%). PPI dose and frequency were the same in 78 (70.9%) and 77 patients (63.6%), respectively. Instructions on PPI timing were the same in 57 patients (47.1%). Laryngoscopy was performed in 135 patients, and 90 of these exams showed evidence of reflux. Upper endoscopy was performed in 96 patients (34.4% with hiatal hernia, 13.5% with esophagitis) and 19 had pH testing (11 with positive results for reflux). Of 17 patients with pH testing and laryngoscopy, 5 (29.4%) had evidence of reflux on both tests.

**Conclusions:** In patients evaluated by ENT and GI, agreement in diagnosis of standard reflux disease is poor, PPI prescriptions between the two specialties are highly variable, and esophageal reflux testing is rarely used.

**Implications for Policy, Delivery, or Practice:** Our results suggest that further work is needed to coordinate care and align management strategies for patients referred to specialty care for reflux disease and symptoms.

**Racial and Ethnic Differences in the Prevalence of Mental Health Service Use among all U.S. Adults and Adults with Serious Mental Illness**

Cristie Glasheen, RTI International; Judith Teich, SAMHSA; Lisa Colpe, NIMH; Sarra Hedden, CBHSQ

**Presenter:** Cristie Glasheen, Ph.D., Behavioral Health and Criminal Justice Division, RTI International, cglasheen@rti.org

**Research Objective:** Studies of mental health service use show that the majority of individuals with disorders do not seek professional help (Jensen & Goldman, 2011; Wang, Lane, et al., 2005). In addition, mental health service use is lower among members of minority communities, compared with non-Hispanic whites (Swartz, Wagner, et al., 1998; Wang, Lane, et al., 2005). This study presents mental health service use for specific race/ethnicity groups among all adults in the US and among adults with serious mental illness using data from the 2008-2011 National Survey on Drug Use and Health (NSDUH).

**Study Design:** This study used data from the 2008-2011 National Survey on Drug Use and Health (NSDUH). NSDUH is an annual survey of the civilian, non-institutionalized population of the United States aged 12 years old or older. The survey collects data on substance use treatment and mental health service use as well as data on the need for treatment and reasons for not receiving treatment.

**Population Studied:** NSDUH data was used to assess the past year prevalence of mental health service use by service type (any, inpatient, outpatient, and prescription medication) among specific race/ethnic groups and by selected demographic and socio-economic characteristics. Prevalence rates were assessed among all adults as well as among adults with serious mental illness.

**Principal Findings:** Preliminary results indicate that the annual average of any mental health service use among all adults in the US was 13.6 percent (se=0.15). Among specific racial/ethnic groups, the prevalence of any past year mental health service use was 5.1 (se=0.53) percent among Asian adults, 7.3 (se=0.32) percent among Hispanics adults, 7.3 (se=0.32), percent among non-Hispanic black adults, and 18.2 (se=1.60) percent among non-Hispanic adults of two or more races, 16.8(se=1.81) percent among American Indian/Alaska Native adults,
been limited to perioperative outcomes with little
the cervical spine is off-label. Prior studies have been limited to perioperative outcomes with little
enhance bone fusion after spine surgery. It is a biologic product intended to

Research Objective: Bone Morphogen Protein (BMP) is a biologic product intended to
improve services for these groups. Initiatives to improve rates of mental health service use in the US, particularly among adults with SMI, will contribute to the overall health of the Nation. These findings suggest that policy makers need to focus on major initiatives to improve mental health service use in the past year. Conclusions: These results show considerable variation in mental health service use by race/ethnicity groups.

Implications for Policy, Delivery, or Practice: Initiatives to improve rates of mental health service use in the US, particularly among adults with SMI, will contribute to the overall health of the Nation. These findings suggest that policy makers need to focus on major initiatives to improve services for these groups.

Complications, Revision Fusions, Readmissions and Utilization Over a One-Year Period Following Bone Morphogenic Protein Use During Primary Cervical Spine Fusions

Adam Goode, Duke University; William J. Richardson, MD, Duke University Medical Center; Robin M. Schectman, MSPH, University of North Carolina Chapel Hill; Timothy S. Carey, MD, MPH, University of North Carolina Chapel Hill

Presenter: Adam Goode, D.P.T., Ph.D., Assistant Professor, Community and Family Medicine, Duke University, adam.goode@duke.edu

Research Objective: Bone Morphogenic Protein (BMP) is a biologic product intended to enhance bone fusion after spine surgery. It is approved for use in the lumbar spine, but use in the cervical spine is off-label. Prior studies have been limited to perioperative outcomes with little investigation of effectiveness. To fill this gap in the literature we assessed: 1) the risk of complications and cervical revision fusions; 2) differences in hospital readmission rates; 3) differences in healthcare services utilization over a one-year period among patients. These findings would improve the understanding of the effectiveness of BMP during primary cervical spine fusions.

Study Design: A retrospective cohort study over a one-year period using data from a large, nationwide multi-payer commercial U.S. claims database.

Population Studied: Patients aged 18 to 64 years old receiving and not receiving BMP at index surgery during a primary (C2-C7) cervical spine fusion.

Principal Findings: There were 61,937 eligible primary cervical spine fusions between 2002 and 2009 of which 1,677 received BMP. The use of BMP was more common among non-capitated insurance types (odds ratio [OR]=1.21 ((95% CI 1.06 to 1.40)) and 4+ levels fused (OR=2.01 ((1.79 to 2.25))). Diagnoses other than disk herniation and degenerative diseases were more likely to receive BMP (OR=1.14 ((95% CI 1.02 to 1.27))). The use of BMP was strongly and independently related to comorbidities, with increasing use of BMP with an increasing number of comorbidities (p<0.001). After adjusting for patient characteristics (i.e., age, sex, levels of fusion, type of fusion approach, diagnosis, insurance type and year of fusion), hospital region and comorbidity using multivariate regression, patients receiving BMP were 38% more likely to have a complication in a one-year period (adjusted odds ratio [aOR]=1.38 ((95% CI 1.20 to 1.58)) and had a significant risk of CNS complication (aOR=1.44 ((95% CI 1.11 to 1.88))). BMP use was not a risk factor for wound, medical or dysphagia/hoarseness complications. A strong risk for cervical revision fusion surgery within a one-year period was found among patients receiving BMP (aOR=1.73 ((95% CI 1.35 to 2.22)). The risk of 30-day readmission was greater with BMP use (aOR=1.37 ((95% CI 1.07 to 1.73)), and re-admission occurred on average 27.4% sooner. Patients receiving BMP were more likely to receive computed tomography scans (aOR=1.38 ((95% CI 1.22 to 1.57)) and epidural injections following anterior surgical approaches (aOR=1.29 ((95% CI 1.00 to 1.65)).

Conclusions: No evidence was found that BMP has a protective effect for any complication or a cervical revision fusion. Patients receiving BMP...
had higher hospital readmission rates and utilized more healthcare services in a one-year period.**

**Implications for Policy, Delivery, or Practice:**
The use of BMP is considered off-label with cervical spine fusions, as the Food and Drug Administration has not approved its use. These findings question the effectiveness of off-label BMP use with primary cervical spine fusions.

**Funding Source(s):** AHRQ

**Impact of a Prior Authorization for Long-Acting Beta-Agonist and Inhaled Corticosteroid Combination Therapy in a Medicaid Population.**

Kathy Ketchum, Oregon State University; Daniel Hartung, Oregon Health & Science University; Dean Haxby, Oregon State University; Luke Middleton, Oregon State University; Kathy Sentena, Oregon State University

**Research Objective:** Evidence suggests that long-acting beta-agonists (LABA) are associated with an increased risk of severe asthma exacerbation. The US Food and Drug Administration and clinical practice guidelines recommend LABA therapy be reserved to those who remain symptomatic on an inhaled corticosteroid (ICS). Despite this, only 20% of patients initiating a LABA appear to be on a previous asthma controller medication. In an effort to improve utilization, the Oregon Medicaid program implemented a prior authorization (PA) policy restricting LABA/ICS combination product use to patients with a recent history of asthma or COPD controller medication use. The objective of this study was to evaluate the impact of this PA on adverse clinical events.

**Study Design:** We conducted a retrospective cohort study using administrative data from the Oregon Medicaid program to compare patients who experienced a PA claim rejection for an ICS/LABA combination product to a historical control group of patients with an incident ICS/LABA prescription in the previous year. The primary outcome was a claim for an asthma or COPD-related emergency department (ED) encounter or hospitalization within 60 days of ICS/LABA claim rejection or incident control fill. Other outcomes included all-cause mortality, ED, hospitalizations, and oral steroid utilization during the same time period. Multivariate logistic regression was used to quantify the association between PA claim rejection and adverse outcomes while adjusting for baseline demographic and disease severity indicators.

**Population Studied:** The study sample included patients with 3 months of continuous Medicaid fee-for-service enrollment before and after their index event (claim reject or control claim fill). Individuals with dual Medicare eligibility, and those less than 5 or greater than 64 years of age were excluded.

**Principal Findings:** A total of 812 patients met inclusion criteria. Of the 278 patients who had a PA rejection, 15 (5.4%) had a subsequent ED or hospitalization for asthma or COPD compared to 21 of 534 (3.9%) of patients in the control group (unadjusted odds ratio (OR) 1.39, 95% CI 0.71 – 2.75). After multivariate adjustment, this association became statistically significant (adjusted OR 2.69, 95% CI 1.23 – 5.88). PA rejection was also associated with oral steroid use within 60 days (adjusted OR 1.93, 95% CI 1.3 – 2.86). There was no association between PA rejection and all-cause hospitalization, ED use, or death (adjusted OR 0.95, 95% CI 0.65 – 1.38). Subgroup effects among those with asthma or COPD at baseline were not statistically significant. Sensitivity analyses assessing outcomes at 30 and 90 days yielded similar findings.

**Conclusions:** Although the overall event rate was low, a PA policy restricting inhaled ICS/LABA appears to increase the risk for adverse outcomes in Medicaid patients.

**Implications for Policy, Delivery, or Practice:** Although efforts were made to minimize disruptions in patients who may have been harmed by treatment delay, policy restrictions that affect individuals with respiratory disease may have undesired consequences and warrant careful implementation and evaluation.

**Dental Service Utilization and Expenditures Among Kansas Medicaid Aged, Blind, and Disabled Beneficiaries**

Jacqueline Hill, University of Kansas Medical Center; Theresa Shireman, PhD, University of Kansas Medical Center

**Presenter:** Jacqueline Hill, M.P.H., Doctoral Student, Health Policy & Management
University of Kansas Medical Center,
jhill6@kumc.edu

Research Objective: Prior to April 2010, oral health services were covered for Medicaid beneficiaries on home and community-based service (HCBS) waiver programs for persons with developmental disabilities (DD), physical disabilities (PD), and the frail elderly (FE) in Kansas. This analysis explores dental service utilization and related expenditures for these Kansas Medicaid populations.

Study Design: We conducted a retrospective, cross-sectional analysis of Kansas Medicaid fee-for-service claims from April 2009 to March 2010. Dental services were identified through procedure codes from outpatient and emergency department (ED) claims. Services were further divided into preventive and non-preventive categories and characterized at the visit-level with associated expenditures.

Population Studied: We studied adults age 18 and older who were continuously enrolled in the Kansas Medicaid fee-for-service program for the 12 month study-period and on HCBS waivers for DD, PD, and FE.

Principal Findings: Of the 22,375 Kansas Medicaid fee-for-service enrollees on HCBS waivers for PD, DD and FE, 21% (N=4,702) had dental claims totaling nearly $2.7 million. Nearly 61% of outpatient dental claims were for preventive services and 75% of these services were performed by dentists. Over 3% of dental service claims were performed in the ED, totaling approximately $57,000. Although each HCBS population comprised nearly one-third of the total eligible study population, nearly 50% of dental service users were enrollees with DD who accounted for 37.5% of total dental costs. Conversely, FE enrollees comprised only 20% of service users, but were responsible for nearly 34% of total dental costs. Moreover, the majority (60.2%) of dental claims among DD enrollees were for preventive services, compared to 26.1% and 18.3% among FE and PD enrollees, respectively.

Conclusions: Only one-fifth of Medicaid enrollees on DD, PD, and FE waivers had dental service claims, implying limited access to these services. In particular, preventive services appear to be underutilized among PD and FE enrollees. Expenditures associated with dental services were lower for DD enrollees, reflecting higher rates of preventive care, while the average cost per dental claim was higher for FE enrollees due to higher rates of non-preventive dental services.

Implications for Policy, Delivery, or Practice: Understanding dental service utilization in this population is important first step in effectively addressing oral health disparities among individuals with disabilities. In 2013, Kansas Medicaid implemented statewide managed care services for all beneficiaries that focus on more integrated, whole-person care with an emphasis on HCBS. Under this reform, ‘value-added services,’ such as preventive dental services are covered for adults age 21 and older. As Kansas Medicaid moves forward with implementing these new services, it will be important to track dental service utilization rates and expenditures, particularly among disabled beneficiaries. Based on our findings, when dental services were previously covered, they were vastly underutilized by disabled beneficiaries, particularly those on PD and FE waivers. However, dental service costs among these beneficiaries were higher, indicating a need for improved dental care coordination to mitigate disparities in oral health access among disabled Medicaid beneficiaries.

Advancing a Common Understanding of Real-World Evidence to Meet Public Health Needs
Sarah Donovan, Avalere Health; Nikita Jeswani, Avalere Health; Elizabeth Guo, Avalere Health; Nicholas Wimbush, Avalere Health; Tanisha Carino, Avalere Health; Gillian Woollett, Avalere Health

Presenter: Nikita Jeswani, B.A., Associate, Evidence-Based Medicine, Avalere Health, njjeswani@avalerehealth.net

Research Objective: The push for value in healthcare has generated growing a interest by payers, providers, clinicians, policymakers, and patients to understand the real-world risks and benefits of therapies. As a result, stakeholders are increasingly demanding non-traditional types of evidence, including real-world evidence (RWE), to answer questions about outcomes that are not adequately captured in randomized controlled trials. Despite investment in new forms of evidence generation, the environment refers to RWE in a variety of ways. Given this lack of consensus on a single definition, we investigated how RWE could be understood so
that stakeholders can effectively generate, communicate, and use RWE to better address public health needs.

**Study Design:** Using publicly available information, we identified a sampling of organizations across stakeholder groups that generate, communicate, and use RWE. In November 2012, we compiled definitions, positions, public statements, methods for RWE generation, and additional information by searching the organizations’ websites, press releases, newsletters, job postings, and publications. We aggregated findings in a database for analysis.

**Population Studied:** We evaluated 50 organizations from the following groups: academia, comparative effectiveness research (CER)/health technology assessment organizations, pharmaceutical manufacturers, patient advocacy groups, payers, professional societies, regulators, and research institutions.

**Principal Findings:** Our analysis showed that though there is a research need for RWE, there is a lack of consensus among stakeholders around how RWE should be defined. Of the organizations assessed, only 38 percent have developed a definition of RWE, and 28 percent did not have readily available information on RWE. We identified several commonalities across the available concepts of RWE. Specifically, organizations noted the need for RWE in post-market CER. However, organizations frequently disagreed on multiple aspects of RWE, including the best approach to address methodological rigor concerns.

**Conclusions:** Given the evolving marketplace for post-market evidence collection (e.g., electronic health records) and growing demands to understand the real-world effects of therapies, the capabilities to generate, communicate, and use RWE are expanding. However, stakeholders, such as the Food and Drug Administration, appear skeptical of this type of evidence, due to a lack of clarity on what RWE is, if it can be methodologically rigorous and reproducible, and how it can be used meaningfully. We propose a conceptual framework for advancing a more common understanding: RWE is research that is designed to answer unique questions that go unanswered by other types of evidence. To ensure that RWE meets public health needs, evidence generators, communicators, and end-users must consider three critical factors when designing studies: meaningful endpoints, appropriate study design, and real-world data sources.

**Implications for Policy, Delivery, or Practice:** If adequately defined and communicated, RWE can provide important insight to the real-world relative risks and benefits of clinical options for patients by assessing endpoints not sufficiently addressed in other types of evidence; confirm the value of medical products through demonstrable outcomes; inform payer decision-making; and support decisions on appropriate clinical treatment pathways in specific therapeutic areas. However, in order for the healthcare industry to successfully utilize RWE, stakeholders need to engage in a dialogue to develop a common understanding of what RWE is and how it can be applied meaningfully.

### The Potential for Care Teams to Positively Influence Quality of Care and Health Outcomes for Mental Health Patients

**Presenter:** Nikita Jeswani, B.A., Associate, Evidence-Based Medicine, Avalere Health, njeswani@avalerehealth.net

**Research Objective:** Recent literature highlights the ability of an effective care team to promote high quality care through care coordination for various patient populations. The increasing severity and prevalence of mental health conditions, combined with the rise in comorbidities in the U.S., have created a lack of clarity on the leadership, composition, and optimal settings for care teams to facilitate care management. Given these complexities, Avalere sought to understand how care teams can engender better management of mental health conditions by patients and health professionals.

**Study Design:** In December 2012, we conducted a white and grey literature search to identify behavioral health homes. We applied National Committee for Quality Assurance (NCQA) patient-centered medical home (PCMH) criteria to determine a set of models to evaluate. From this set, we profiled three models as case studies. To assess the composition, team member roles, and support tools utilized by care teams, we researched websites, press releases,
Population Studied: We examined the following behavioral health home models across three distinct geographic regions: Rhode Island Chronic Care Sustainability Initiative, Maimonides Medical Center - Brooklyn Care Coordination Consortium, and Depression Improvement Across Minnesota Offering a New Direction. 

Principal Findings: We determined that when implemented appropriately, the use of care teams can produce tremendous improvements in healthcare quality. Though composition and roles of each of team member varied significantly, leadership by a care manager and family member participation was foundational to each institution’s care team approach. Consistent with NCQA standards, care teams that measured best practices and focused on care coordination by centralizing care around a single manager, partner, or navigator achieved notable early success in outcomes and cost savings.

Conclusions: Findings from early behavior health home models show that holding a team accountable for individual patient needs leads to better quality of care. Building a partnership and mutual trust among practitioners, patients, their families, caregivers, and advocates empowers patients to proactively manage their mental health conditions. Care teams in these delivery models have demonstrated early success, but there is room for improvement. Specifically, care team roles and composition need to be more clearly defined. While there are numerous accreditation programs for PCMHs, there is a need to prioritize the development of qualifying criteria for behavioral health homes.

Implications for Policy, Delivery, or Practice: As the composition of innovative care delivery models continues to evolve, care teams can be utilized as a mechanism to improve care coordination and promote high quality care for patients. Additional research is needed to define optimal structure and unique roles of team members before incorporating care teams into a behavioral health home model. As organizations consider potential standards for behavioral health homes, the inclusion of specific care team criteria focused on best practices will be essential to achieving quality improvement.

Poster Session and Number: C, #944
the differences in access when local non-VHA stroke facilities were included. All GIS analyses were conducted using the ARC-GIS software version 10 from ESRI (Redlands, CA).

**Population Studied:** All VHA enrollees aged 65 and older and VHA patients diagnosed with acute stroke.

**Principal Findings:** We identified 4,694,511 VHA enrollees in FY2010 who were older than 65 years of age and 59,127 unique patients with acute stroke between FY2006 and FY2010. Based on recently mandated VHA stroke center criteria, there are 65 VHA medical centers providing acute stroke care (including 33 full-time primary stroke centers and 32 limited hours stroke facilities) and 1,074 Joint Commission certified non-VHA Primary Stroke Centers across the nation. Our GIS analyses showed that (1) 1,277,099 (27.2%) VHA enrollees over the age of 65 and 28,094 (47.5%) patients with acute stroke lived within 60-minute driving time from a VHA stroke center. With the addition of the non-VHA private stroke centers, the overall 60-minute driving time coverage would increase from 27.2% to 41.7% for VHA enrollees over the age of 65 and from 47.5% to 61.2% for acute stroke patients.

**Conclusions:** While up to 47.5% of the VHA enrollees and 61.2% of the VHA stroke patients could potentially receive acute stroke care intramurally or extramurally, creative solutions are required to increase access to acute stroke care for the Veterans residing beyond 60-minute driving time from a VHA and/or non-VHA stroke facility.

**Implications for Policy, Delivery, or Practice:** Treatment of acute stroke patients in stroke centers increases the odds that patients receive tissue plasminogen activator (tPA) which has been demonstrated to decrease stroke morbidity. The ultimate goal of this study was to make strategic recommendations to VHA policy makers regarding the locations of VHA facilities capable of delivering acute stroke care, and the use of potential alternate strategies such as tele-stroke care or outsourcing to community stroke centers where VHA resources are lacking.

**Effects of Telerehabilitation on Functional Outcomes and Health-Related Quality of Life**

Huanguang Jia, Rehabilitation Outcomes Research Center; Charles E. Levy, Rehabilitation Outcomes Research Center, North Florida/South Georgia Veterans Health System, Department of Veterans Affairs; David L. Omura, William Jennings Bryan Dorn VA Medical Center, Department of Veterans Affairs; Paul M. Hoffman, Veterans Rural Health Resources Center – East Region, Department of Veterans Affairs; Diane C. Cowper Ripley, Rehabilitation Outcomes Research Center, North Florida/South Georgia Veterans Health System, Department of Veterans Affairs; William B. Mann, Rehabilitation Outcomes Research Center, North Florida/South Georgia Veterans Health System, Department of Veterans Affairs

**Presenters:** Huanguang Jia, PhD, Research Health Scientist, North Florida/South Georgia Veterans Health System, Department of Veterans Affairs, Rehabilitation Outcomes Research Center, Huanguang.Jia@va.gov

**Research Objective:** The Veterans Health Administration (VHA) of the Department of Veterans Affairs (VA) currently enrolls 3.3 million rural Veterans, and approximately 43% (2.27 million) of the VHA patients with a service-connected disability live in rural areas. Telerehabilitation is expected to play an important role in meeting the needs for rehabilitation care and expanding healthcare access for the Veterans with disabilities residing in rural areas. In this study, we assessed the functional outcomes, health-related quality of life (HRQoL) and satisfaction among a group of Veterans who participated in the Rural Veterans Telerehabilitation Initiative (RVTRI) program between February 22, 2010 and April 1, 2011.

**Study Design:** This retrospective, pre-post study included 54 Veterans enrolled in the RVTRI. Functional outcomes were measured by Functional Independence Measure (FIM), Quick Dash (QuickDASH), the Montreal Cognitive Assessment (MoCA), and Two-Minute Walk Test (2MWT). HRQoL was assessed using the Veterans RAND 12-Item Health Survey (VR-12). Satisfaction was evaluated using a telehealth satisfaction scale. All these outcomes measurements were collected at Veterans’ admission and discharge date from the RVTRI, except for satisfaction which was measured solely at discharge. Veterans’ residential and the VHA hospital ZIP codes were used to calculate travel distances.

The RVTRI network system consists of two sets of endpoints (video codecs) connected via an encrypted secure VA Expressway. One endpoint was located at the provider’s work station behind the VA firewall; the other was...
located at the participating Veteran's home. Rehabilitation therapy was delivered by a Cisco-Tandberg E. 20 video phone and/or Tandberg's Movi 2/3 software installed on a personal computer equipped with a web camera. A Wilcoxon signed-rank test was used to compare the difference in the repeated outcome measures.

**Population Studied:** Community-dwelling Veterans were enrolled at a local VA medical center following an initial in-person assessment. Veterans who required hands-on rehabilitation (i.e., manual mobilization) were excluded.

**Principal Findings:** The study cohort consisted of 94.5% male, 63.0% between 50-64 years of age, and 53.7% diagnosed with neurological and/or musculoskeletal disorders. On average, the participants were in the program for 95.4 (SD=43.4) days and received 9.8 (SD=43.3) therapeutic sessions. The RVTRI program helped save an average total of 1,679.1 (SD=2,115.2) travel miles, 28.0 (SD=35.3) driving hours, and $696.80 (SD=$877.80) of VHA travel reimbursement per Veteran, excluding costs for hotel, meals, child care, and lost work time. Our Wilcoxon signed-rank test showed a significant improvement in the participants' FIM (p<0.0001, r=0.3), MoCA (p=0.0003, r=0.4), the 2MWT (p=0.0031, r=0.8), and VR-12 (p=0.0316, r=0.2) scores. The upper-limb functional restoration assessed by QuickDASH was not significant. Ninety-eight percent (98.0%) of the participants were very satisfied with the telerehabilitation experience.

**Conclusions:** Delivering needed real-time and appropriate rehabilitation therapy through the RVTRI program at participating rural Veteran's homes demonstrated a significant and large effect on improving the participants' two-minute walking distance, a significant and medium effect on improving the participants' functional independence and cognitive function, and a significant but small effect on the participants' HRQoL.

**Implications for Policy, Delivery, or Practice:** These results suggest that in-home telerehabilitation via internet connected videophones can be a viable alternative to rehabilitation care delivery.

**Development of a Vertical Equity Measure for a Federally-Funded Cancer Control Program**

Kristy T. Joseph, Centers for Disease Control and Prevention; Kristy Joseph, Centers for Disease Control and Prevention; Ketra Rice, ORISE; Chunyu Li, Centers for Disease Control and Prevention

**Presenter:** Kristy Joseph, B.S. Accounting M.A. Economics, Public Health Analyst, Division for Cancer Control and Prevention, Centers for Disease Control and Prevention, vio5@cdc.gov

**Research Objective:** The goal of the Centers for Disease Control and Prevention’s (CDC) Colorectal Cancer Control Program (CRCCP) is to increase colorectal cancer screening rates to 80 percent by 2014 in funded States through promotion efforts which includes evidence-based interventions, policy and systems changes and the provision of screening to low-income, uninsured adults ages 50-64. Ensuring equitable funding for all grantees is important to maximize the return on investment. A funding equity measure should convey procedural justice (fair process) and support distributive justice (fair outcomes) for grantees. CDC is developing a new funding process that supports a more equitable distribution of resources. The purpose of this study was to develop a measure to promote funding equity.

**Study Design:** Using CRCCP program and state-level population data, a vertical equity measure was developed and calculated for each grantee. Vertical equity asserts an unequal, but equitable distribution of funding based on need. The denominator is the proportion of the funding awarded to an individual grantee to total funds awarded for a given year. The numerator represents the proportion of a grantee’s population eligible for screening compared to the total CRCCP population. The equity measure reflects how a 1 percent increase in funds yields a given percentage increase in population reached. Next, we grouped grantees with like characteristics at the state and program levels to represent need. Equity measures were compared within and across groups to establish vertical equity (i.e., high or low) and compared to group-level means.

**Population Studied:** 25 State CRCCP grantees were studied to establish vertical equity. Characteristics included in the analysis were: (1) State-level population characteristics (e.g., socioeconomic composition, colorectal cancer screening and mortality rates, rural/urban landscape) and (2) program structure (e.g., grantee organizational capacity).

**Principal Findings:** Vertical equity measures ranged from 0.15-5.44 percent, an average of...
0.98 percent, illustrating the wide range of funding levels to the proportion of the eligible population. Results demonstrate existing inequalities in the current funding distribution. For example, a grantee in one group had the lowest funding award ($527,000), but the highest proportion of population need (0.12) and lowest CRC screening rate (57%). The vertical equity measure for this state was .66 percent, meaning that a 1 percent increase in funds will yield an increase of .66 percent population reached.

**Conclusions:** Applying a vertical equity measure may contribute to an equitable funding process and improved program outcomes. In moving toward a more equitable distribution of funds, all CRCPP grantees have a balanced opportunity to reach the program goal of 80 percent screening rates.

**Implications for Policy, Delivery, or Practice:** Public health organizations could more justifiably distribute funds and better maximize outcomes by using an equity measure in their funding processes. By establishing groups based on diversity of need, funding ranges could be established to systematically ensure an equitable treatment of like grantees.

**Cost per Treated Patient for Biologics in Rheumatoid Arthritis in Medicaid**

Machoan Bonafede, Truven, Andover, MA, USA; George Joseph, Amgen; George Joseph, Amgen Inc., Thousand Oaks, CA; Nicole Princic, Truven, Cambridge, MA, USA; David Harrison, Amgen Inc., Thousand Oaks, CA

**Presenter:** George Joseph, Ph.D., M.S., Senior Manager, Global Health Economics, Amgen, gejoseph@amgen.com

**Research Objective:** To estimate annual cost per treated patient for the Tumor Necrosis Factor (TNF) blockers etanercept, adalimumab and infliximab in rheumatoid arthritis (RA) in patients covered by Medicaid.

**Study Design:** For this retrospective cohort study, the MarketScan Medicaid Multistate Database was used to identify adult patients, age 18 or over with one or more claim for a biologic of interest between January 1, 2007 and December 31, 2011. A subject’s first claim preceded by at least 6-months of enrollment and followed by 12 months of continuous enrollment was their index claim and defined their index date and treatment cohort. Patients had to have a diagnosis of RA in the 6-months preceding their index date. Patients with other conditions treated with these agents including psoriasis, psoriatic arthritis, ankylosing spondylitis, Crohn’s disease, or ulcerative colitis pre-index were excluded. “Continuing” patients had one or more claim for their index biologic before their index date, “New” patients did not. Mean monthly dose and total dose of other biologics after discontinuation of their index biologic was calculated for the 12-months after index. Wholesale acquisition costs and the Medicare Physician Fee Schedule were applied to the mean monthly dose and related drug administration to calculate cost per treated patient in US dollars.

**Population Studied:** Adult Medicaid patients with RA treated with etanercept, adalimumab or infliximab between January 1, 2007 and December 31, 2011.

**Principal Findings:** A total of 1,085 patients were included; 48% received etanercept at index (n=521); 37% received adalimumab (n=405); and 15% received infliximab (n=159). Patient characteristics were similar across groups; mean age 47.4 years (SD=10.7) and 83% were female. For all patients, the annual RA biologic cost per treated patient was $15,747 for etanercept, $17,939 for adalimumab and $20,445 for infliximab. For all agents, annual costs were lower for new patients, $15,352 for etanercept, $16,222 for adalimumab and $19,067 for infliximab than for continuing patients, $16,199 for etanercept, $20,922 for adalimumab, and $21,706 for infliximab. The proportion of patients remaining on their index agent was also higher for continuing patients, 49% for etanercept, 47% for adalimumab, and 58% for infliximab compared to 38% for etanercept, 34% for adalimumab, and 36% for infliximab in new patients.

**Conclusions:** Based on drug utilization in this Medicaid population, etanercept had the lowest cost per treated patient in RA in both new and continuing patients. The higher cost for continuing patients was partially driven by higher persistence. Both etanercept and adalimumab which are self-injected were less expensive than infliximab, which is infused.

**Implications for Policy, Delivery, or Practice:** There are meaningful differences in annual drug costs for patients starting on different TNF blockers which may be an important consideration when designing formulary and reimbursement policies in Medicaid.

Poster Session and Number: C, #948

Disseminating CER-Based Models for Substance Misuse and Depression in Primary Care Clinics across Four States Keith Kanel, Pittsburgh Regional Health Initiative; Robert Ferguson, Pittsburgh Regional Health Initiative

Presenter: Keith Kanel, MD MHCM FACP, Chief Medical Officer, Pittsburgh Regional Health Initiative, kanel@jhf.org

Research Objective: The research objectives for the Partners in Integrated Care consortium include: (1) establish a multi-state partnership that includes three Chartered Value Exchanges (CVEs); (2) develop an implementation strategy that addresses both system- and practice-level barriers to widespread implementation; (3) increase the number of primary care practices implementing IMPACT for depression and SBIRT for substance misuse; (4) increase the number of eligible patients who receive these CER-based services; (5) reduce symptoms of depression and frequency of substance misuse; and (6) recruit another CVE through the Network for Regional Healthcare Improvement as a dissemination site.

Study Design: The consortium is led by the Pittsburgh Regional Health Initiative (PRHI). Each of the organizations in the consortium is responsible for regional implementation, which includes recruitment, training, coaching, learning collaboratives, data collection, and regional policy work. The Steering Group oversees five work groups that include members from each of the partnering organizations.

Principal Findings: Regarding recruitment, the following can present challenges: finding and paying for a consulting psychiatrist, practice and staffing constraints (limited resources), commitment to other projects, provider and staff inexperience and discomfort with team care, and the reimbursement equation. However, strong leadership and an understanding of the what’s in it for me statement can trump these concerns. Regarding implementation, even if a primary care site is simply adding SBIRT to an existing IMPACT infrastructure, implementation and training still require substantial effort, resources, support, culture change, and leadership. Also, an electronic care management tracking system is critical for care management, caseload review, and data collection. Regarding dissemination, cultural and regional differences trump standardized terminology and training and implementation strategies.

Conclusions: Disseminating CER-based models in different regions with unique histories, policies, and cultures requires adaptations; however, standardization is necessary for model fidelity and aggregating data. Future work is needed to determine how to design the organizational structure of the consortium to standardize model fidelity and data collection, while allowing local adaptation.

Implications for Policy, Delivery, or Practice: Four factors are necessary to sustain CER-based care delivery models: alignment of local, state, and federal quality measures; new types of payment; changes in legislation; and provider leadership.

Patient-Centered Medical Homes and Physician Assistant Education Gerald Kayingo, Yale School of Medicine

Presenter: Gerald Kayingo, Ph.D., M.M.Sc., P.A., Instructor, Physician Associate Program, Yale School of Medicine, gerald.kayingo@yale.edu

Research Objective: The Patient-Centered Medical Home (PCMH) utilizes interprofessional teams to deliver quality healthcare in a manner that focuses on the patients’ needs. Despite being prominently featured in the Affordable Care Act, little is known about the impact of the PCMH on medical education and how institutions are preparing students to provide care in this new model. The aim of this project is to determine the extent to which Physician Assistant (PA) students are exposed to elements of the PCMH during the didactic and clinical phases of their education.

Study Design: In 2012, using Survey Monkey, a prevalidated survey was distributed to American PA programs. The survey inquired about curricula central to practice in the PCMH; team based care, electronic medical record utilization and principles of care coordination. The study protocol was approved by the Yale School of Medicine Human Investigation Committee.
**Population Studied:** Physician Assistants

**Principal Findings:** Seventy-eight clinical coordinators (49%) completed the survey of which 94% stated they teach principles of team-based practice, 71% instruct their students in the use of the electronic medical record, 61% expose the students to care coordination, and 30% teach them about payment structures that reward care coordination and high quality care, while 22% stated students do not have exposure to the PCMH. Most importantly less than 25% of programs utilize designated PMCH clinical sites and those that do have been doing so for less than two years.

**Conclusions:** The data indicate that many PA programs introduce concepts of the patient-centered medical home in the lecture hall but few PA students’ are exposed to medical homes during clinical training.

**Implications for Policy, Delivery, or Practice:** This project is among the first of its kind to study the PCMH and PA Education and has identified areas for further research that may prepare PAs to function better in team based practices.

**The Impact of Payment Reform on Rural Medicare Advantage Enrollment and Quality**

Leah Kemper, Washington University in St. Louis; Abigail Barker, PhD, Washington University in St. Louis; Timothy McBride, PhD, Washington University in St. Louis

**Presenter:** Leah Kemper, M.P.H., Policy Analyst, Brown School of Social Work, Washington University in St. Louis, kemper@wustl.edu

**Research Objective:** This project examines the implications of changes in Medicare Advantage (MA) payment implemented in the Affordable Care Act (ACA) and in the current Centers for Medicare and Medicaid (CMS) demonstration of quality-based bonus payments. We focus on two key issues: (1) how the changes to MA payment, including bonus payments linked to quality-based star ratings, could impact the plans available to rural beneficiaries, and (2) the likely impact of these changes on rural enrollment in MA plans.

**Study Design:** We analyze MA enrollment and quality as a function of geography as well as the benchmark and quality bonus payments received by the plans, and we generate results using both the parameters established by the ACA and the current CMS demonstration. Thus, the research focuses on the significantly higher quality-based bonus payments due to lower qualification criteria, and it also measures the impact of transitioning to the quality parameters established by the ACA as the demonstration concludes.

**Population Studied:** The population studied is the entire Medicare population within the U.S. The unit of analysis is the county level.

**Principal Findings:** We find that rural MA payment will decline in most areas, but it will not be as negatively impacted as many urban areas. In addition, we find that rural MA plans have lower quality than urban MA plans due to rural enrollment being concentrated in PPOs rather than HMOs, which generally have higher quality ratings. Therefore, rural areas will receive smaller quality bonus payments, especially once the demonstration program ends. However, we also identify specific quality indicators that account for the majority of the difference in quality among rural and urban plans, and we categorize these with regard to their implementation feasibility.

**Conclusions:** Some of the reductions in MA payment that will occur with the implementation of the ACA will be offset by quality-based bonus payments. Rural areas have lower average quality ratings and less HMO enrollment; therefore, they won’t benefit significantly from the ACA quality payments. As demonstration bonus payments end in 2014 and the transition to the new MA payment structure begins, these reductions in payment could have an impact on MA enrollment and plan availability going forward.

**Implications for Policy, Delivery, or Practice:** Due to the provision that ties benchmark payments to a county’s relative fee-for-service costs, rural areas will experience a smaller decline in payment than urban areas. However, going forward, rural areas are unlikely to benefit much from the quality-based bonus payments due to the lower average quality scores of rural plans. As we look at the quality measures that could feasibly be addressed by rural MA plans to improve quality, we predict that these actions are likely to generate only modest quality gains. Thus, policymakers concerned with strengthening the presence and quality of MA in rural areas should consider expanding the quality thresholds which define the bonus payments to allow for incremental improvements in quality, thus encouraging the marginal
improvements which are in many cases the only feasible goal for plans in rural areas.

**Prevalence and Predictors of Chronic Pain in the US Adult Population: New Data from the 2010 NHIS QOL Supplement**

Taylor Schraudner, WSU Department of Health Policy and Administration; Jae Kennedy, Washington State University, Spokane; Sean Murphy, WSU Department of Health Policy and Administration; Sterling McPherson, WSU College of Nursing

**Presenter:** Jae Kennedy, Ph.D., Professor, Health Policy and Administration, Washington State University, Spokane, jjkennedy@wsu.edu

**Research Objective:** The objectives of this study are to 1) develop current population estimates of chronic pain, and 2) identify factors associated with chronic pain.

**Study Design:** Prevalence estimates and logistic regression models using data from the 2010 National Health Interview Survey (NHIS) Quality of Life (QOL) Supplement. The supplement includes information about quality of life indicators like communication limitations; self-care capacity; mental health concerns like depression and anxiety; physical limitations and fatigue; and general measures of chronic pain. This study will define chronic pain as pain persisting for at least 3 months, broadly consistent with the American Chronic Pain Association and American College of Rheumatology definitions (and different from site specific pain measures used in the main NHIS and other surveys like the NHANES).

**Population Studied:** General health data on US households was generated from the three components (core groups) of the 2010 NHIS. This included the interviews of 89,976 persons in 35,117 families. The 2010 Quality of Life Supplemental Survey was randomly assigned to roughly one quarter of the Sample Adult Core (N=6,775). The sample group for this inquiry was limited to non-institutionalized adults over the age of 18.

**Principal Findings:** Analysis of NHIS data indicates a national chronic pain prevalence estimate of approximately 19%. In multivariate logistic models, chronic pain is significantly more prevalent among women (OR=1.5; 95% CI, 1.2-1.8); adults who rate their health as fair or poor (OR=2.8; 95% CI, 2.2-3.6); adults who report symptoms of depression (OR=2.6; 95% CI, 1.7-4.0); adults who are limited in ability to work and/or self-care (OR=4.6; 95% CI, 3.6-5.8); adults who were hospitalized one or more times in the previous year (OR=1.5; 95% CI, 1.2-1.9); and adults who are overweight (OR=1.4; 95% CI, 1.1-1.8) or obese (OR=1.6; 95% CI, 1.3-1.9). Chronic pain is less common among nonwhites (OR=0.5; 95% CI, 0.4-0.7) and Hispanics (OR=0.5; 95% CI, 0.4-0.7). Rates of chronic pain are lowest for adults aged 18-29 (7.6%), and peak at age 60-69 (OR=2.8; 95% CI, 1.9-4.1).

**Conclusions:** Approximately 39 million adults in the US report pain lasting longer than 3 months. Pain is associated with a variety of health and disability measures.

**Implications for Policy, Delivery, or Practice:** Assessing chronic pain is a critical component of quality of life measurement. Individual suffering, paired with the high costs of pain treatment, make the widespread prevalence of chronic pain an important public health concern. Timely and appropriate treatment of chronic pain could significantly improve quality of life, particularly for adults with chronic health conditions.

**Beverage Consumption and Individual-Level Association in South Korea**

Euna Han, Gachon University; Tae Hyun Kim, Yonsei University; Lisa M. Powell, University of Illinois at Chicago

**Presenter:** Tae Hyun Kim, Ph.D., Assistant Professor, Graduate School of Public Health & Institute of Health, Yonsei University, thkim@yuhs.ac

**Research Objective:** Few previous studies investigated consumption distributions of sugar sweetened beverages (SSBs) over time and individual-level associations in Asia despite of the recent interest in SSBs regarding obesity control. This study aimed to provide recent evidence on beverage consumption trends from 2001 to 2009 for overall and subtypes of SSBs and for milk as a comparable healthy beverage in South Korea. In addition, we also explored individual socioeconomic factors associated with SSB consumption in South Korea.

**Study Design:** The Korean National Health and Nutrition Examination Surveys during 2001-2009 were used. Consumption prevalence and average caloric intake by SSB type were
examined. Associations of socioeconomic status (SES) with consumption were assessed in a logistic regression model (consumption prevalence) and in a two-part model (overall caloric intake adjusting consumption probability).

**Population Studied:**

**Principal Findings:** SSB consumption prevalence increased to 38%, 69%, 70%, and 50% by 2009 up from 31%, 66%, 63%, and 32% in 2001 among young adults, adults, and elderly, respectively. Miscellaneous SSBs (sports/energy drinks, coffee/tea products, flavored milk, and others) were the most prevalent and their prevalence increased among adults (from 62% to 69%) and elderly (from 30% to 47%) between 2001 and 2009. Adolescents consumed the largest calorie from miscellaneous SSB in all beverage types despite that the prevalence of its consumption was lower than regular soda and milk in both 2001 and 2009. Women (only the top-income group) and men in higher income groups showed higher consumption odds of total SSB (OR=1.18-1.25), soda (OR=1.18, men only), fruit drinks (OR=1.18, the top-income only for both genders), and miscellaneous SSBs (OR=1.1-1.2). Men with higher-education showed higher odds of total SSB consumption (OR=1.14-1.20), and all subtypes of SSBs (OR=1.18, 1.29, 1.19 for soda, fruit drinks, and miscellaneous SSBs, the top-education group only). There were only minimal differences in the overall amount of caloric intake from SSBs by individual SES for both genders.

**Conclusions:** South Korea is following the global nutrition transition toward greater consumption of SSBs. However, the prevalence was higher among high SES-people for fruit drinks and miscellaneous SSBs like other developed countries. Further research is needed to build the international evidence base.

**Implications for Policy, Delivery, or Practice:**

**Socioeconomic Factors with the Unmet Medical and Dental Needs of Elderly Koreans**

Nam-hee Kim, Yonsei University; Ji-Eun Jeon, Yonsei University; Yang-Heui Ahn, Yonsei University; Chun-Bae Kim, Yonsei University

**Presenter:** Nam-hee Kim, Ph.D., M.P.H., Assistant Professor, Dental Hygiene, Wonju College of Medicine, Yonsei University, nami71@yonsei.ac.kr

**Research Objective:** In Korea, the elderly population has been increasing exponentially, too. Medical expenses for the elderly account for more than 30% of total national medical costs. However, the demand to address the unmet medical and dental needs of the elderly persists. This study aims to reveal the socioeconomic factors related to the unmet medical and dental health needs of the Korean elderly.

**Study Design:** We conduct a cross-sectional study based on secondary data analysis. The data used in this study was sourced from the 4th Cycle of the Korean National Health and Nutrition Examination Survey (KNHANES?), conducted by the Korea Centers for Disease Control and Prevention (KCDC) for a period of three years (2007–2009). These samples were collected through a three-stage stratified cluster sampling method, taking into account the residence area, housing type, and age.

**Population Studied:** A total of 3,578 elderly subjects (weighted n = 4,566,263) aged 65 years and older were selected. The dependent variables were the rate of unmet medical needs and the rate of unmet dental needs. The “percentage of subjects who did not receive necessary care when needed within the past year” was calculated for medical and dental care respectively. Five socioeconomic factors were set as independent variables. These included residential area, education, income, type of guaranteed health insurance, and enrollment in private health insurance. Statistical processing was conducted using complex sample multiple regression analysis with adjustments for age and gender. The PASW statistics 19.0 (SPSS Inc, Chicago, IL, USA) was used.

**Principal Findings:** The results show that 23% of elderly experienced unmet medical needs. A much higher percentage (36%) experienced unmet dental needs. After adjusting for age, gender, and socioeconomic factors, the income was determined associated with unmet medical needs. Compared to the group with the highest income level, the group with the lowest income level had an 8% higher rate of unmet medical needs. On the other hand, the socioeconomic factors associated with unmet dental needs were income and type of guaranteed health insurance. The unmet dental needs in the lowest income level group were 10% higher compared to the highest income level group (p < 0.05). Also, subjects on medical aid had a 13.5% higher rate of unmet dental needs compared to those enrolled in local health insurance (p < 0.05).
Conclusions: In the Korean elderly, unmet dental needs are a more serious issue than unmet medical needs. The income of the elderly is the greatly affects their unmet medical and dental needs. In particular, the degree of unmet dental needs showed significant differences depending on the extent of health insurance benefits.

Implications for Policy, Delivery, or Practice: It is necessary to continue providing the social support for low-income elders. It is evident that the National Health Insurance does not fulfill all of their unmet medical and dental needs. Thus, it is crucial to address the unmet dental needs of the Korean elderly by expanding health insurance coverage and reducing dental co-payments for them.

Depression and Mortality among Persons With Diabetes: Are Older Adults at Higher Risk? - Results from the Translating Research Into Action for Diabetes Study

Lindsay Kimbro, University of California, Los Angeles; W. Neil Steers, UCLA; Carol M. Mangione, UCLA; O. Kenrik Duru, UCLA; Andrew J. Karter, Kaiser Permanente Northern California; Laura McEwen, University of Michigan; Susan L. Ettner, UCLA;

Presenter: Lindsay Kimbro, MPP, Project Manager, Department of General Medicine, University of California, Los Angeles, lkimbro@mednet.ucla.edu

Research Objective: Several studies have found that depression is linked to an increased risk of mortality among diabetic patients. However, these studies do not show the modifying effect of age on the association of depression with mortality. The purpose of this paper is to test whether the depression-mortality association varies in magnitude between elderly and non-elderly diabetic populations.

Study Design: We used data from the Translating Research Into Action for Diabetes (TRIAD) Study. TRIAD is a multicenter prospective longitudinal study of persons with diabetes in managed care settings. Depression was measured by the Patient Health Questionnaire (PHQ8), and those with a score of 10 or greater were classified as depressed. We tracked mortality in this sample for 5-6 years after the wave 2 survey was completed using the National Death Index (NDI). We conducted a survival analysis with depression as the key predictor adjusting for patient demographic and health variables and including fixed effects for each research site on our full sample, followed by stratified analyses on two subsamples—those age 65 and over, and those under age 65.

Population Studied: This analysis includes data from 3,341 diabetic persons aged 18 and over who participated in wave 2 of the TRIAD survey, which is the wave in which depression was measured.

Principal Findings: After controlling for age, gender, race/ethnicity, income, and other comorbidities, mortality risk among depressed persons in the full sample was 49% higher than among non-depressed persons (p<.01). This was consistent with the findings of previous studies. However, in age-stratified models, the results were different. After controlling for the same variables, mortality risk among persons over the age of 65 years with depression was 78% greater than among elderly diabetic persons without depression (p<.01). For the less than 65-year-old cohort, the effect of depression on mortality becomes small and insignificant (p = .36).

Conclusions: This analysis suggests that the effect of depression on mortality among diabetic persons is most important for older adults. This could be a result of a greater effect of non-adherence to medication or other diabetic care due to depression, the interaction of depression and diabetes with other age-related comorbidities, or a lower level of depression diagnoses and treatment among the older populations.

Implications for Policy, Delivery, or Practice: Elderly persons with diabetes should be considered a high priority population for depression screening and treatment. As some depression treatments have been shown to have negative effects on other diabetes related health factors, it is vital to recognize, diagnose, and treat depression in older adults as quickly as possible.

Improving Care for Patients with End Organ Failure – A Singapore Experience

Hui Nah Tan, Agency for Integrated Care, Singapore; Alvin Koh, Agency for Integrated Care; Irwin Chung, Agency for Integrated Care, Singapore; Loong Mun Wong, Agency for
Integrated Care, Singapore; Jason Cheah, Agency for Integrated Care, Singapore; Alvin Koh, Agency for Integrated Care, Singapore

**Presenter:** Alvin Koh, Manager, Regional and Primary Care Department, Agency for Integrated Care, alvin.koh@aic.sg

**Research Objective:** The HOME (HOlistic Care for MEdically Advanced Patients) Programme is the first palliative home care programme for non-oncology patients in Singapore. This programme aims to validate the local use of advance care planning (ACP) in these patients and provide a multidisciplinary approach to care at the end of life. This service provides symptom relief, ACP and bereavement counselling in the patients’ homes, as well as coordinates care with relevant medical specialists. This study looks at the impact of the HOME programme on respecting patient choices at the end of life and hospital utilisation.

**Study Design:** This study is based on patients enrolled in the HOME Programme from May 2008 to March 2011. Data is gathered from administrative databases and compared against historical controls. Key outcomes studied include completion of ACP, hospital utilisation data including readmission rate, and place of death. The hospitalisation episode that resulted in death was excluded from the data analysis for both the control and the intervention group.

**Population Studied:** Suitable patients with end-stage lung, renal and heart disease were identified during hospitalisations in three public healthcare institutions with a life expectancy of less than 1 year. A total of 489 patients were recruited from May 2008 to March 2011. Retrospective controls were chosen based on deaths in the same hospitals with matched ICD codes.

**Principal Findings:** Of the patients recruited, 22.3% had chronic obstructive pulmonary disease, 34.4% had heart failure and 43.3% had end-stage renal failure. 100% of mentally and emotionally competent patients completed advance care planning. It also demonstrated lower hospital utilisation with a 30 and 180 day readmission of 5.5% and 19.4% compared with 22.8% and 44.4% in controls. Patients also showed a higher percentage of deaths at home (68%) compared with national norms (28%).

**Conclusions:** This study validated the use of ACP in patients with heart, kidney or pulmonary end-stage disease in Singapore, with improved understanding and respect for patient’s choices, as well as demonstrated reduction in hospital utilisation.

**Implications for Policy, Delivery, or Practice:** Improving medical technology and increasing prevalence of chronic diseases result in more patients living with organ failure. While these patients often have a more uncertain prognosis compared with advanced oncology patients, the palliative care model can still play a significant role in improving their quality of life. The HOME Programme provides holistic, humane and benevolent care to patients with end-stage organ failure in the home environment guided by the ACP and helmed by a group of dedicated palliative care physicians, nurses and counsellors.

Findings suggest that this program should be continued from both the patients and systems perspective, and further research done to analyse if this programme would benefit other types of patients with end-stage organ failure.

**National Care Transition Program Cuts Hospital Admission of High Risk Patients**

Shiou-Liang Wee, Agency for Integrated Care, Singapore; Alvin Koh, Agency for Integrated Care; Ganga Ganesan, Ministry of Health, Singapore; Chun Liang, Ministry of Health, Singapore; Jason Yap, Agency for Integrated Care, Singapore; Faezah Binte Shaikh Kadir, Agency for Integrated Care, Singapore; Loong-Mun Wong, Agency for Integrated Care, Singapore; Jason Cheah, Agency for Integrated Care, Singapore

**Presenter:** Alvin Koh, Manager, Regional and Primary Care Department, Agency for Integrated Care, alvin.koh@aic.sg

**Research Objective:** Elderly patients with complex care needs frequently require care from different healthcare settings. Poor coordination during transitions across health services can compromise patient safety, create undue stress and increase costs. Transitional care interventions for carefully selected patients from hospital to other settings had shown promise in reducing rates of subsequent hospitalizations. We evaluated the effectiveness of ACTION (Aged Care TransitlON), a state funded national care transition care program involving Singapore’s five largest public hospitals to reduce acute care utilization.
**Study Design:** We compared the risk of unplanned hospital re-admission and emergency department (ED) attendance of acutely ill patients on ACTION program to other patients admitted during a similar time frame, matched for age, gender and hospital subsidy status. Propensity (conditional probability of enrolment into program) scores were derived by multiple logistic regression with the covariates age, gender, length of initial hospital stay, Charlson index, past 180 days hospital admission, past 180 days ED attendance. A logistic regression model was fitted to the data. Unplanned rehospitalisation and ED attendance were compared after covariate adjustment and weighting by propensity scores.

**Population Studied:** Suitable patients were identified and recruited into ACTION program during hospitalisations. The program, delivered by dedicated care coordinators, is goal-oriented and time-limited (1-3 months) to complete the care recipient’s restorative process and assist them and their families to make long term arrangement for care. We performed a retrospective cohort study of 4132 patients in ACTION program discharged from the five acute hospitals from Feb 2009 to Jul 2010 and 4132 control patients chosen from the State Hospital Claim System.

**Principal Findings:** The baseline characteristics of patients in the two groups were similar after weighting by propensity. Baseline characteristics for ACTION patients were: age (SD) 79.2 (7.7) y, 44% male, mean length of hospital stay (SD) 11.6 (13.0) days, mean Charlson index (SD) 1.6 (1.8), mean no. of hospitalization and ED attendance 180 days prior to index admission were 0.79 (1.4) and 1.9 (2.0) respectively. Subjects enrolled on the program were less likely to have unplanned rehospitalization and ED visit. The adjusted odds ratio (95% CI) comparing rehospitalization and ED re-attendance of program subjects with that of controls at 30 days, were 0.5 (0.5, 0.6) and 0.8 (0.7, 0.9) respectively; and at 180 days, were 0.6 (0.6, 0.7) and 0.9 (0.8, 1.0) respectively.

**Conclusions:** Supporting vulnerable patients and their caregivers to take a more active role during care transition through a care transition program is effective in reducing subsequent rehospitalization and ED attendance in acutely ill patients at risk for transitions.

**Implications for Policy, Delivery, or Practice:** Efforts to reduce rehospitalizations should focus on identifying vulnerable patients for comprehensive assessment, improving discharge planning and introducing inexpensive methods of linking with community care services to enhance communication during and after discharge from hospital.

**The Impact of Recommendations and Patients’ Resources on the Distance Travelled to a Hospital for Breast Cancer Surgery**

Florian Koelsch, University of Cologne - IMVR; Christoph Kowalski, University of Cologne; Lena Ansmann, University of Cologne - IMVR; Holger Pfaff, University of Cologne - IMVR

**Presenter:** Christoph Kowalski, M.A., Dr., Research Associate, IMVR, University of Cologne, christoph.kowalski@uk-koeln.de

**Research Objective:** In 2003, the German federal state of North Rhine-Westfalia (population 17.8m) established an accreditation system for breast care centers that led to the standardization and improvement of care quality, as well as to the closure of hospitals that could not fulfill the requirements. Despite the improvement in all hospitals, a significant proportion of patients (who have free hospital choice in Germany) still travel to distant hospitals. We investigated whether recommendations of a hospital by relevant others and patient resources are associated with the choice of a hospital that is not the closest to the patient’s home.

**Study Design:** The analyses were based on data from 4,529 patients treated in 88 hospitals that were included in a patient survey in 2011. Distances from the patients’ homes to the closest eligible hospitals and the chosen hospital were calculated. Logistic regression analyses were estimated to identify factors associated with choosing a hospital other than the closest eligible one, controlling for socio-demographic, disease and treatment characteristics.

**Population Studied:** Breast cancer patients.

**Principal Findings:** Approximately 45% of patients chose a hospital other than the closest eligible one. Higher education, private health insurance, living with a partner, young age and lower self-rated health were associated with choosing a distant hospital (model 1). No impact was found for cancer stage, having children, native language, or cancer site. After adding
recommendations by relevant others (model 2), references from friends/family and health insurance companies were associated with choosing a distant hospital, whereas recommendations by the patients’ gynecologists and mammography facilities were associated with choosing a nearby hospital. No significant association was found for the family doctor’s recommendation.

Conclusions: Resources such as living with a partner and higher socioeconomic status facilitate patients choosing a distant hospital.

Implications for Policy, Delivery, or Practice: Gynecologists and mammography facilities appear to play a crucial role in allocating patients to hospitals. It is unclear why their recommendations differ from those of health insurance providers and friends/family.

Poster Session and Number: B, #505

**QUEST Collaborative improvement in Mortality, Quality and Cost of Care Compared to U.S. Hospitals**

Marla Kugel, Premier Incorporated; John Martin, Premier, Inc.; Eugene Kroch, Premier, Inc.; Michael Duan, Premier, Inc

Presenter: Marla Kugel, M.P.H., Principal Research Scientist, Public Affairs, Premier Incorporated, marla_kugel@premierinc.com

Research Objective: To compare the change in mortality and cost of care as well as the result of the first year of the inpatient Value-Based Purchasing (VBP) program among hospitals in the QUEST collaborative over time to a nationally matched sample of hospitals not part of the QUEST collaborative.

Study Design: QUEST charter member hospitals were compared to hospitals not associated with the collaborative. A matched case-control analysis was implemented for comparing observed to expected mortality ratio. Hospitals were matched on the following hospital characteristics: size, teaching status, geographic region, and urban location. Case-mix adjusted costs per discharge were measured using administrative claims data from MedPAR from 2006 through the third calendar quarter of 2011. CMS released inpatient VBP payment adjusters were used to determine how the QUEST and non-QUEST cohorts fared under the new payment program.

Population Studied: Matched controls were selected from all inpatient prospective payment system (IPPS) hospitals with no missing data in the MedPAR inpatient discharge claims data from federal fiscal year (FFY) 2006 through FFY 2011 for the mortality comparison. All IPPS hospitals never enrolled in QUEST was the comparison group for cost per discharge and VBP payment adjustment.

Principal Findings: QUEST hospitals went from having a 3 percent lower average observed to expected (O/E) mortality ratio in FFY 2006 to a 17 percent lower average mortality O/E ratio in FFY 2011 compared to the matched cohort of non-QUEST hospitals (O/E of 0.97 QUEST and 1.14 non-QUEST). The average case-mix adjusted CMS calculated cost of care per discharge was approximately $45 (0.8 percent) greater in federal fiscal year 2006 and $92 (-1.3 percent) less by FFY 2011. Approximately 64 percent of QUEST hospitals eligible for the FY 2013 inpatient VBP program that joined the collaborative prior to 2010 will receive incentive payments greater than their contribution payments compared to 50 percent of the non-QUEST matched controls.

Conclusions: The QUEST Collaborative performed better than a national cohort of matched hospitals in mortality and show signs of better performance in quality of care (although not statistically) and cost as measured by the CMS program in FFY 2013. Most of these findings were consistent over multiple years of measurement where data was available.

Implications for Policy, Delivery, or Practice: The QUEST program was developed to help facilities improve patient outcomes via measurement in multiple domains, provision of intervention material, and sharing of best practices. Currently, healthcare systems are seeking to improve patient quality, processes, efficiency and experience; all while reducing costs of care. The results from this evaluation demonstrate that through collaborative activities and transparency in measurement this goal can be achieved.

**The Patient Experience Consistency Score in Medicare Inpatient Value-Based Purchasing – Rewarding Consistently Low Performance?**

Marla Kugel, Premier Incorporated; Danielle Lloyd, Premier, Inc.; Christine Van Dusen, Premier, Inc.
**Research Objective:** To determine if the consistency score portion of the patient experience domain score (based on measure results from the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) tool) associated with the Medicare inpatient Value-Based Purchasing (VBP) program is rewarding hospitals for consistently low performance.

**Study Design:** Scores for the eight individual HCAHPS measures and the consistency score were calculated using measure data submitted by hospitals in 2009 and 2010 for the baseline and performance period respectively, using the FY 2013 final inpatient Value-Based Purchasing (VBP) benchmark and achievement thresholds published in the VBP Program final rule. The consistency score assigns the maximum 20 points to a hospital if the lowest HCAHPS measure is at or above the achievement threshold. Consistency scores were compared to the distribution of “high” and “low” individual measure scores. A low score was defined as a value less than or equal to 2 points; a high score was defined as a value greater than or equal to 6 points. These values corresponded approximately to the median and 90th percentile of score values across HCAHPS measures.

**Population Studied:** All inpatient prospective payment system hospitals eligible for the inpatient VBP program according to inclusion criteria and measure data minimums specified in the VBP Program final rule.

**Principal Findings:** There are 3,054 hospitals eligible for the FY 2013 inpatient VBP program according to the data time periods used. The maximum number of points for the consistency score is 20, which is worth 20 percent of the patient experience domain score for FY 2013 VBP. Consistency score average value was 16.1 and the median value was 17. Almost two-thirds of hospitals had a majority of individual HCAHPS measures with a score of 2 or less (61.4 percent). About one-third (28.5 percent) of these low performing hospitals had a consistency score of 17 or greater and no measures with a score of 6 or better. Six percent of hospitals scoring the maximum number of consistency points had 4 or more individual measures scoring 2 or less; however that percentage increases to 47 percent for a consistency score of 19. More than half of these hospitals had no individual measures with high scores (score of 6 or greater).

**Conclusions:** Hospitals with consistently low scores are being assigned a higher than average consistency score. This will have an impact on the total performance score and thus how the hospital is rewarded under the inpatient VBP program.

**Implications for Policy, Delivery, or Practice:** The results question the current inclusion of the consistency score as part of the total domain score for patient experience. The consistency score calculation may need to be modified to reward hospitals for performing consistently well and encourage hospitals to perform better.

**Funding Source(s):** No Funding

**Outcomes of African American Patients with Metastatic Renal Cell Carcinoma Treated with Standard First Line Therapy**

Adam Kuykendal, University of North Carolina, Chapel Hill Cecil B. Sheps Center; Anna C. Snavely, University of North Carolina at Chapel Hill; William Y. Kim, University of North Carolina at Chapel Hill

**Research Objective:** Metastatic renal cell carcinoma (RCC) is a disease that kills approximately 13,000 people in the United States every year. RCC does not affect all racial groups equally as African Americans as compared to Caucasians have a higher incidence, younger age of onset, shorter progression free survival and shorter overall survival. Established prognostic factors including lab values, extent of disease and performance status can be used to separate patients into well-defined groups of good, intermediate and poor risk. Between 2005 and 2010 3 new oral drug therapies, all Vascular Endothelial Growth Factor Receptor Tyrosine Kinase Inhibitors (VEGFR-TKIs), were FDA approved for first line treatment of metastatic RCC. These drugs became the standard of care for first line therapy in good and intermediate risk metastatic RCC patients and one option for first line therapy for poor risk patients. However, the phase III trials supporting their approval were conducted with minimal African American patient participation. No studies have
specifically examined the effectiveness of standard first line therapy (VEGFR-TKIs) for metastatic RCC in African Americans.

**Study Design:** This was a retrospective cohort design. Our institution’s electronic medical record was searched from 2004-2012 for all patients with metastatic RCC. The medical records of all Caucasian and African American individuals started on first line VEGFR-TKI therapy with at least one follow up visit were abstracted for self-reported race, type of treatment, prognostic variables, date of progression as defined by the treating physician, and other demographic and clinical variables. The Social Security Death Index was used to establish date of death. Overall survival and time to progression were analyzed using Kaplan-Meier and Cox proportional hazards models.

**Population Studied:** 34 Caucasian patients and 12 African American patients with metastatic RCC treated with first line VEGFR-TKI therapy were included.

**Principal Findings:** African American patients exhibited worse prognostic factors with 54.6% classified in the poor risk group compared with 10.7% of Caucasians. African American patients compared to Caucasian patients had a non-significant trend toward worse overall survival (HR 1.49, p 0.36) and time to progression (HR 1.59, p 0.27). After adjustment for risk group we found very similar results between the two races for overall survival (HR 1.00, p 0.99) and progression free survival (HR 1.26, p 0.66).

**Conclusions:** This is a small preliminary study that suggests first line VEGFR-TKI therapy is an effective choice for African American patients and that metastatic RCC responds to treatment similarly in African American versus Caucasian patients.

**Implications for Policy, Delivery, or Practice:** While multi-site studies would be needed to confirm these results, the data suggest that providers should feel comfortable treating African American patients with first line VEGFR-TKI therapy.

**Funding Source(s):** AHRQ

**Poster Session and Number:** B, #508

**The Influence of Sensory, Functional and Activity Limitations on Employment Disparities**

Debra L. Brucker, Institute On Disability, University of New Hampshire; Eric Lauer, University of New Hampshire; Purvi Sevak, Department of Economics, Hunter College; Andrew J. Houtenville, Institute On Disability, University of New Hampshire

**Research Objective:** National surveys which measure the prevalence of limitations are used to provide estimates of how health conditions are functionally limiting individuals in society and their impact on other outcome disparities (e.g. employment). We investigated the association of employment outcomes with sensory, functional and activity limitations. We tested the hypothesis that the employment outcomes of people with sensory and functional limitations (Group A) will be lower than the employment outcomes of people without sensory and functional limitations (Group B), controlling for environmental and other personal characteristics. In addition, we tested whether employment outcomes for people with sensory, functional, and activity limitations (Group C) have lower employment outcomes than the remaining people in Groups A or remaining people in group B, controlling for environmental and other personal characteristics.

In addition, we tested the hypothesis that the screening mechanics of the surveys used has a significant effect on self-reported limitation, resulting in a different association between limitation and employment outcomes (survey effect). Specifically, individuals may only be asked about the presence of a difficulty or impairment if they first reported having an activity limitation.

**Study Design:** Ordinary least squares methods were used to model regressions on the outcome of employment – working or not, and then estimate regressions on the outcomes of hours, and wages (measured in the natural log of wages). Employment was modeled as a function of sensory, functional and activity limitations, demographic characteristics, and state fixed effects. Demographic variables include age, race, gender, educational attainment, marital status, number of children, and urbanicity. State fixed effects are used to control for the environment.

**Population Studied:** Our sample consists of respondents to the American Community Survey (ACS, 2009-2011) and Medical Expenditure Panel Survey (MEPS, 2009-2011) ages 18-64 with and without any reported limitation. Survey
items included sensory (hearing and vision), functional (ambulation and cognition) and activity limitations (independent living). Demographic items included age, gender, race, and educational attainment.

**Principal Findings:** Individuals who self-report limitations have poorer employment outcomes than individuals who do not report such limitations, controlling demographic characteristics. In addition, individuals who self-report more than one limitation have worse employment outcomes than individuals reporting only one limitation.

**Conclusions:** In the context of public health, sensory, functional and activity limitations are thought to arise from health conditions. Once health conditions reach a certain severity they directly impact an individual’s ability to attain and maintain employment. Limitations can be conceptually used as a proxy for the presence of a health condition severe enough to cause a limitation as perceived and reported by an individual.

**Implications for Policy, Delivery, or Practice:** A major issue in disability and health policy is the definition of disability. Disability is frequently defined as the presence of a limitation or impairment (such as blindness and deafness) that limits at least one major life activity (e.g., the Americans with Disabilities Act of 1990) or that limits a specific major life activity, such as work (e.g., Social Security Disability Insurance). Such approaches do not directly include individuals with health conditions and mitigating personal and environmental factors such that they are not limited (hence the American with Disabilities Act Amendments Act of 2008, which extended the ADA to cover those with such mitigating measures). Future policy initiatives should take this into account, especially when attempting to disentangle health and disability within national survey results founded on these definitions.

**The Value of a Health System-Based Comparative Effectiveness Center**
Brian Leas, University of Pennsylvania Health System; Matthew Mitchell, University of Pennsylvania Health System; Julia Lavenberg, University of Pennsylvania Health System; Kendal Williams, University of Pennsylvania Health System; Craig Umscheid, University of Pennsylvania Health System

**Presenter:** Brian Leas, M.S., M.A., Research Analyst, Center for Evidence-based Practice, University of Pennsylvania Health System, brian.leas@uphs.upenn.edu

**Research Objective:** In 2006 the University of Pennsylvania Health System created a Center for Evidence-based Practice (CEP) to support the quality, safety and value of patient care. The Center is distinctive, as one of few health-system based research institutions that conducts rapid-cycle comparative effectiveness reviews to address daily patient care and real-time decisions about quality, care delivery, policy development, and purchasing. CEP synthesizes published and local evidence to inform clinicians and administrators throughout the health system, and supports the development of computerized clinical decision support interventions. We examined the Center’s nearly seven year history to identify the impact and value provided by a hospital-based comparative effectiveness research center.

**Study Design:** CEP produces multiple types of reports that reflect the needs of end users and the scope of the literature. Products include: original systematic reviews with meta-analyses; concise synopses of clinical guidelines and published systematic reviews; inventories of published studies that serve as environmental scans and enable efficient decision making about future review priorities; and special reports on policy issues affecting the health system. The Center also contributes to the development of clinical decision support interventions and practice guidelines. CEP’s research reports and administrative records were reviewed and analyzed.

**Population Studied:** CEP is funded by the health system’s Chief Medical Officer with an annual budget of approximately $750,000. The Center is staffed by two physician co-directors trained in epidemiology, three research analysts, physician and nurse liaisons, a statistician, economist, and librarians totaling 5.5 FTE. CEP examines a broad range of topics, including processes of care, devices, drugs, diagnostic tests, and health system policy.

**Principal Findings:** The Center has completed over 200 reports since its inception. The median time from project opening to first draft report is four weeks, which is rapid compared to the development timeline of more traditional comparative effectiveness reviews. During its first few years, CEP’s primary clients were
purchasing committees and administrative leadership, but clinical departments now account for close to half of the reviews. Patient safety and quality improvement are often the primary goal of initiating CEP reviews, while value based purchasing and organizational efficiency are also important factors. Several recent, high impact initiatives have incorporated CEP reviews into strategic decision making, including efforts to reduce preventable readmissions, promote appropriate screening, and support workforce management.

Conclusions: An evidence-based practice center within an academic medical center can offer systematic evaluations of high impact clinical questions, support information management infrastructure, and enable efficient management of healthcare resources. Besides informing clinical practice, such evaluations can promote a culture of evidence-based decision-making and drive quality improvement.

Implications for Policy, Delivery, or Practice: CEP presents its reviews to the original requestors to inform decision making, and we often work with key stakeholders to implement our findings. Evidence reviews are shared publicly through the National Guideline Clearinghouse, the Cochrane-indexed HTA database, and peer-reviewed publications. CEP also offers education through workshops, courses for faculty, staff and trainees, and academic detailing. In addition, CEP contracts with the CDC to develop national infection control guidelines, and in 2012 partnered with the ECRI Institute as one of 11 AHRQ-designated Evidence-based Practice Centers.

Segmentation for Health Information Channels according to Themes in a Metropolitan City of Korea
Sang Soo Bae, Health Services Research Center, Hallym University; HeyJean Lee, Kangwon National University Hospital

Presenter: HeyJean Lee, M.D., Clinical Assistant Professor, Department of Preventive Medicine, Kangwon National University Hospital, vishue@ewhain.net

Research Objective: Information is important resource for health. Self management of lifestyle disease become important. Disease information contribute to patient’s relief and health behavior change. Health information retrieval depends on individual and channels may differ according to themes.

Study Design: We conducted a telephone survey. We asked the main channel to retrieve health information according to themes. Themes were chronic disease, healthy lifestyle, and mental health. We also collected data about sociodemographic characteristics, concern about community news, concern about public health information, self check of health, and perception about living environment.

Population Studied: We selected 1,048 dwellers in a district of Metropolitan City. We considered gender, age for selection.

Principal Findings: 839 people(80.1%) have retrieved all the information about chronic disease, healthy lifestyle, and mental health. Chronic disease information retrievers can be segmented by age, self checking for health, concern about public health information, and income. 20s and 30s mainly use TV and Internet. Whereas 20s and 30s who checking health regularly get information not only from TV and Internet but also from professional. 50s and 60s mainly get information from TV and professional. 40s with low income less use the newspaper. For Healthy lifestyle and mental health, people concerning about public health information use the Internet more. Whereas people do not concern about public health information get more information from neighbors.

Healthy lifestyle and mental health retrievers can be segmented by age and concern about public health information. 20s and 30s mostly use TV and Internet. 40s who concern about public health information more use the Internet but who do not frequently get information from neighbors.

Conclusions: People show different patterns and associated factors in health information retrieval according to the themes they want.

Implications for Policy, Delivery, or Practice: To provide public health information well, it would be helpful to design and customize information for themes according to segmented population.

The Relationship between Nurses’ Work Value and Patient-Centred: Moderating Effect of Organizational Playfulness
Jui-fen Rachel Lu, Department of Health Care Management, College of Management, Chang
Developing a Model-based Risk Index for Unplanned 30-Day Hospital Readmissions
Klaus Lemke, Johns Hopkins University

Objective: To develop a 30-day all-cause readmission risk model for unplanned acute care hospitalization after an initial hospitalization for any condition. Alternating inpatient and outpatient episodes of care were created from longitudinal claims data. Model vectors included healthcare utilization, care coordination, medication adherence, and comorbidity measures. Features were derived from claims data with the Johns Hopkins ACG® System for risk adjustment and predictive modeling. Features for pairs of inpatient and outpatient episodes were combined, and patients with recurrent readmissions had multiple model vectors. The framework enables the development of a readmission risk prediction model for peri-discharge prioritization of patients for care transition programs.

Study Design: Retrospective study using longitudinal claims and enrollment data from the IMS Health LifeLink™ Health Plan Claims Database. Three years of claims data from 2009 to 2011 from a single health plan were used. The data included individual medical services and filled prescriptions. Planned admissions were identified using an algorithm developed by

Gung University; I-chen Lee, Chang Gung University, College of Management

Presenter: I-chen Lee, PHD, Assistant Professor, Industrial and Business Administration, Chang Gung University, College of Management, ichen@mail.cgu.edu.tw

Research Objective: This study aims to investigate relationships among nurses' work value, organizational playfulness, and patient-center attitude, and examines if work value has moderating effect.

Study Design: Questionnaire Survey.

Population Studied: This study's subjects are nurses at Hospitalization department in Taiwan's biggest medicine center. The inclusion criteria includes: 1. To Select full-time nurses, so as to increase comparison chances. 2. Among excluding list are head nurses, ward manager, nursing practitioners, students of nursing department, interns. That is because the above people with such statuses or positions all have works which are different from others that need to share nursing duty on rotation basis. Therefore they are excluded. 3. Those people who serve more than 6 months in this hospital. With that we can avoid introducing the interference form factors as career and role adaption to this study. In total 300 copies of questionnaires are distributed and 290 effective copies are responded, with response rate at 96.7%.

Principal Findings: 1. Organizational playfulness is negatively related to patient-center attitude (β=.193, p<.01), which indicates that the higher the organizational playfulness, the lower the patient-center attitude.

2. Affective value in work value is positively related to patient's central attitude (β=.208, p<05), which indicates that nurses who have higher affective value will have higher patient-center attitude.

3. Affective value has positively moderating effect on organizational playfulness and patient-center attitude (β=.173, p<.05).

Conclusions: Supposing that nurse's affective value is lower, a higher level of organizational playfulness will lead to lower patient-center attitude. However when nurse's affective value is higher, a higher level of organizational playfulness will be instrumental to patient-center attitude.

Implications for Policy, Delivery, or Practice: Past literature indicates that the organizations which have stronger organizational playfulness will have more flexibility in their institutions. Their works are more challenging in nature. Their leaders will be more humorous. The management level will have less obvious distinction with general employees. Team members will cooperate and trust with each other. The former three characteristics are rather different from characteristics of medical institutions. The latter two characteristics are rather similar to characteristics of medical institutions. Therefore the role played by organizational playfulness in medical institutions has to fit with the individual work value of nurses. As such it will be instrumental in displaying a higher patient-center attitude in an appropriate organizational playfulness climate, thereby enhancing patients' well-being.

Funding Source(s): Other, National Science Council, Taiwan
Poster Session and Number: B, #512
the Yale New Haven Health Services Corporation that uses procedure codes and discharge diagnosis categories. Admissions for childbirth were excluded. Logistic regression was used to fit the model. We applied the methods described by Sullivan et al. (2004) to create a readmission risk index.

**Population Studied:** Persons of all ages with health insurance, mostly in employer-sponsored managed care plans, also Medicaid recipients and Medicare beneficiaries of all ages. Study subjects were admitted as inpatients to an acute care hospital for non-childbirth conditions and were enrolled for at least 30 days post-discharge.

**Principal Findings:** The study population of 113,137 persons had 180,628 inpatient admissions over three years. Of all admissions, 11.8% occurred within 30-days. Risk factors with significant (p-value < .001) odds ratio estimates between 1.4 and 2.6 were insurance status, low birth weight, disability, frailty, count of prior hospitalizations, and likely coordination risk. Factors with odds ratios significantly below 1.0 were presence of dialysis services, nursing services, count of active ingredients, length of hospital stay, presence of major inpatient procedure, count of emergency room visits, and count of outpatient management visits. The c-statistic for this model was .92. The best-performing model additionally included 184 significant comorbidity markers from the ACG system and produced a c-statistic of .95. Medication adherence markers and an inpatient procedure classification marginally improved model performance. The readmission risk index used fewer risk factors with good predictive performance.

**Conclusions:** A readmission risk model using an episode-based approach and time-varying predictors derived from claims data resulted in intuitive patterns of risk factors and excellent model performance. A readmission risk index was derived.

**Implications for Policy, Delivery, or Practice:** Model-based prioritization of discharged patients for care transition management enables hospitals to augment the prioritization of patients who will benefit from transition management to outpatient care and be less likely to be readmitted within a 30-day period.

**Moderating Role of Work-Family Balance on Hospital Medical Directors’ Patient-Related Work Stresses and Health**

Min-Hsun Liu, China Medical University; Blossom Yen-Ju Lin, China Medical University; Yung-Kai Lin, Taichung Veterans General Hospital; National Chung Hsing University; Cheng-Chieh Lin, China Medical University; Blossom Yen-Ju Lin, China Medical University

**Presenter:** Blossom Yen-Ju Lin, Ph.D., Professor, Department of Health Services Administration, China Medical University, yenju1115@hotmail.com

**Research Objective:** Previous studies have demonstrated that hospital medical directors, who are senior physicians in management positions with high job demands in clinical practices and management, have a lower self-rated health. By considering the work stress of hospital medical directors, this study examined how their work-family balance might moderate work stress regarding their health.

**Study Design:** This was a cross-sectional survey study. A developed and structured questionnaire encompassed the dimensions of patient-related work stress (i.e., physician-patient relationship stress and patient condition stress; 10 items), self-rated health status (2 items) and health complaints (26 self-reported symptoms in 1 month short-term or more than 6 months long-term), work-to-family (6 items) and family-to-work (6 items) balances, and personal and work characteristics. Factor analyses were performed for the constructs of physician-patient relationship stress, patient condition stress, work-to-family balance, and family-to-work balance into factor scores for further analysis. The Cronbach’s alpha values were 0.890–0.916. Hierarchical regressions were performed. According to the logic of risk and protective factors, statistically significant increases of R2 (p<.05), when the work stress factors and interaction terms were entered, showed that the levels of work stress directly affected the hospital medical directors’ self-rated health, and that their work-family balance had moderate effects. SPSS statistical software 20.0 was used in this study.

**Population Studied:** The study population totaled 2,245 hospital medical directors identified on the hospital websites of all of the accredited hospitals in Taiwan. Between August and November 2009, each hospital medical director was surveyed by mail. A total of 737
valid respondents yielded a response rate of 32.83%.

**Principal Findings:** Of the responding hospital medical directors, 92% were male, 94% were married, 93% lived with others (family or friends), and the average age was 49 years. On average, the responding hospital medical directors were living with 1.4 children and 0.3 elderly people. Regarding work environments, 24% of the responding hospital medical directors worked in medical centers, 49% worked in regional hospitals, and 28% worked in district hospitals. In addition, 59% of the respondents worked in public hospitals and had been working as medical practitioners for 21.5 years and in their current hospitals for 13.1 years, on average. Controlling for the personal and work characteristics revealed that hospital medical directors’ work stress in physician-patient relationships was negatively related to their perceived health status compared to the general population and their self-reported short-term health complaints. The hospital medical directors’ family-to-work balance could moderate the negative effects of their physician-patient relationships on short-term health complaints and improved health complaints.

**Conclusions:** Hospital medical directors’ work stress in physician-patient relationships was found to have more negative effects on their self-reported health status and complaints; and family-to-work balance was found to have moderating effects on hospital medical directors’ health complaints in this study.

**Implications for Policy, Delivery, or Practice:** More personnel benefits and fringe planning could be employed in the human resource management of health care facilities for enhancing hospital medical directors’ possible family-to-work interfere other than their family (or personal) supports should be called for.

**Moderating Role of Work-Family Balance on Dentists’ Patient-Related Work Stresses and Health: A Nationwide Survey Study**

Kuang Ting Hsiao, China Medical University; Blossom Yen-Ju Lin, China Medical University; Lih-Jyh Fuh, China Medical University; Cheng-Chieh Lin, China Medical University; Blossom Yen-Ju Lin, China Medical University

**Presenter:** Blossom Yen-Ju Lin, Ph.D., Professor, Department of Health Services Administration, China Medical University, yenju1115@hotmail.com

**Research Objective:** Work stress has been reported to be a major cause of dentists’ self-perceived health, health related behaviors, retirement, musculoskeletal disease, and premature disability caused by trauma. Work-life balance has been emphasized in the new era of workplace life. This study examined how work-family balance might moderate dentists’ work stress regarding their health.

**Study Design:** This was a cross-sectional survey study. A developed and structured questionnaire encompassed the dimensions of patient-related work stress (i.e., dentist-patient relationship stress and patient condition stress; 10 items), self-rated health status (2 items) and health complaints (26 self-reported symptoms in 1 month short-term or more than 6 months long-term), work-to-family (6 items) and family-to-work (6 items) balances, and personal and work characteristics. Factor analyses were performed for the constructs of dentist-patient relationship stress, patient condition stress, work-to-family balance, and family-to-work balance into factor scores for further analysis. The Cronbach’s alpha values were 0.826–0.923. Hierarchical regressions were performed. According to the logic of risk and protective factors, statistically significant increases of R2 (p<.05), when the work stress factors and interaction terms were entered, showed that the levels of work stress directly affected the dentists’ self-rated health, and that work-family balance had moderate effects. SPSS statistical software 20.0 was used in this study.

**Population Studied:** By using a systematic sampling method, 1,100 dentists were each mailed a questionnaire, encompassing approximately 10% of the updated national certified dentist lists in Taiwan. Between August and November 2009, 531 dentists responded, yielding a response rate of 48.27%.

**Principal Findings:** Of the responding dentists, 73% were male, 74% were married, 88% lived with others (family or friends), and their average age was 43.26 years. On average, the responding dentists were living with 1.1 children and 0.7 elderly people. Regarding work environments, 63% of the responding dentists worked in clinics and 37% in hospitals, and 85% worked in private organizations and had been working as dental practitioners for 17 years and
in their current organizations for 12 years, on average. Controlling for the personal and work characteristics revealed that the surveyed dentists' patient relationships and patient condition work stress levels were negatively related to their perceived health (compared with the general population and medical peers) and their short-term and long-term health complaints. However, only family-to-work balance could have moderate effects on the dentists' patient condition work stress levels.

**Conclusions:** All types of work stress in dentist-patient relationships and patient conditions were negatively related to the dentists' health. However, we find that only dentists' family-to-work balance is a key to relieve their work stress of patient conditions for better self-reported health.

**Implications for Policy, Delivery, or Practice:** Future studies have to explore other potential factors related to improving dentists' stress levels of dentist-patient relationships in the workplace.

**Funding Source(s):** Other, Year grant from Department of Health, Executive Yuan, Taiwan, R.O.C. (DOH98-NNB-1046)

**Poster Session and Number:** B, #515

**Complications after Outpatient Colonoscopy: A Multilevel Analysis**

Xinliang Liu, University of Central Florida

**Research Objective:** Colonoscopy is recommended for polyps and cancer screening in average risk person, aged between 50 and 75. It is estimated that over 14 million colonoscopies are performed annually in the United States. Several studies focused on patient-level factors that may affect the development of some complications after the procedure. But few examined the impact of organizational and market-level factors. This study examined the impact of patient demographic and clinical characteristics, organization-level factors, and characteristics of the local healthcare market.

**Study Design:** This study was observational and cross-sectional in nature. Same day ED visit or hospitalization, 30-day serious gastrointestinal events resulting in ED visit or hospitalization, and 30-day non-gastrointestinal events resulting in ED visit or hospitalization were used to quantify complications developed after outpatient colonoscopy. Three-level generalized hierarchical linear models (GHLM) were used to examine factors at patient, facility, and market levels.

**Population Studied:** The study population was patients who underwent outpatient colonoscopy between January 1, 2005 and November 30, 2007 in California. Hospital emergency department and inpatient discharge records were merged to the outpatient surgery data. The final sample contained 1,278,886 colonoscopy cases.

**Principal Findings:** After controlling for confounding factors, the study found that senior age, being covered by Medicaid, greater Charlson Index or the number of ED visits or hospitalizations in the prior six months, and receiving more invasive procedures (colonoscopy and biopsy or lesion removal colonoscopy) versus diagnostic colonoscopy were associated with higher probability to experience related complications after colonoscopy. Among organizational-level factors, having moderate or high facility colonoscopy volume was associated with lower odds for two to three of the four quality measures. At the market level, higher HHI index (lower competition level in the market) was associated with higher odds for same day ED visit or hospitalization and 30-day non-gastrointestinal events resulting in ED visit or hospitalization. The uninsured rate was associated with lower odds for 30-day other gastrointestinal events resulting in ED visit or hospitalization. The uninsured rate was associated with lower odds for 30-day other gastrointestinal events resulting in ED visit or hospitalization and 30-day non-gastrointestinal events resulting in ED visit or hospitalization.

**Conclusions:** Organization- and market-level factors together with patient-level factors can affect a patient's likelihood to develop complications after outpatient colonoscopy. But the set of factors that are associated with a certain type of complication may vary. Future studies of quality of ambulatory surgical procedures should consider a systematic exploration of relevant factors at multiple levels.

**Implications for Policy, Delivery, or Practice:** This study provided useful information about how to identify patient subgroups that are prone to develop certain type of complications after outpatient colonoscopy. Such information should be made available to physicians, health care
Variation in the Utilization of Blood and Blood Products in the Acute Care Setting: Opportunities for Reducing Costs and Saving Lives

Timothy Lowe, Premier Incorporated; Raymond Perigard, Premier Inc.; Eugene Kroch, Premier Inc.; John Martin, Premier Inc.; Richard Bankowitz, Premier Inc.

Presenter: Timothy Lowe, Ph.D., M.S.W., Principal Research Scientist, Premier Incorporated, timothy_lowe@premierinc.com

Research Objective: Transfusion of blood products, including whole blood, red blood cells, platelets, plasma and cryoprecipitate, is a critical part of clinical care, responsible for saving up to 4.5 million Americans each year, or nearly 10,000 lives per day. Overuse or inappropriate use of blood products is a frequently unrecognized problem that presents significant patient safety issues. Recent research indicates that use of blood products beyond a level deemed medically necessary can increase complication rates and length of hospitalization. Overuse can also substantially increase the cost of care. This research examined variations in blood product use and potential opportunities for improvement.

Study Design: De-identified patient data from 7.4 million discharges between April 1, 2011 and March 30, 2012 were analyzed. Individual hospitals’ blood utilization for whole blood, red blood cells, platelets, plasma and cryoprecipitate, were compared to a benchmark set of utilization rates using negative binomial regression with adjustment for patient DRG assignment, 3MTM APR-DRG Severity of Illness assignment, licensed acute care beds, teaching status, geographic region, and urban/rural population served. Benchmarks were defined as the trimmed mean utilization rate for the first quartile of facilities (best performers). The number of lost opportunities (defined as blood product utilization above benchmark by DRG assignment for each patient) were multiplied by blood product acquisition costs to convert lost opportunities to U.S. dollars.

Population Studied: Analyses used clinical, administrative and supply chain data from patients with similar conditions (DRG assignment) at 464 U.S. acute care hospitals contained within a database maintained by Premier, Inc., Charlotte, NC.

Principal Findings: Results across all 464 hospitals show that, to treat similar patients, the top performing quartile of hospitals used fewer units of all blood products. Summation of all lost opportunities resulted in (36,501; $1.8M) whole blood, (358,617; $75.7M) red blood cells, (134,642; $71.9M) platelets, (183,850; 11.2M) plasma, and (89,106; $4.4M) cryoprecipitate, or a potential savings of $165M annually. The largest volume of potential opportunity identified for all blood and blood products were in internal medicine (196,698 units), followed by cardiac surgery (167,490 units), and general surgery (156,325 units). Data for the top ten inpatient diagnoses (by DRG) showed that the largest opportunity for utilization reduction were sepsis (35,560 units), total joint replacement (34,087 units), and cardiac valve and other cardiothoracic procedures (28,752 units).

Conclusions: If all hospitals analyzed were able to achieve blood product utilization similar to that of the top performing quartile, blood product use would be reduced by 802,000 units, with a combined savings of $165 million annually, while maintaining positive patient outcomes.

Implications for Policy, Delivery, or Practice: Identification of areas for cost reduction within hospitals and health systems is essential to reigning in excessive healthcare spending and keeping up with the proposed reductions in payments to healthcare providers. The lost opportunities identified in this analysis only capture the cost of product purchasing. Other cost savings may be achievable due to the additional expenses associated with blood testing, and with the storage, transportation and administration of blood products.

Funding Source(s): No Funding

The Quality and Productivity Connection: Can Hospitals Improve Quality While Managing Labor Expense?

Timothy Lowe, Premier Incorporated; Doug Miller, Premier Inc.; Eugene Kroch, Premier Inc.; John Martin, Premier Inc.; Richard Bankowitz, Premier Inc.

Presenter: Timothy Lowe, Ph.D., M.S.W., Principal Research Scientist, Premier Incorporated, timothy_lowe@premierinc.com
Research Objective: As healthcare expenditures continue to rise, government and private payers are searching for ways to reduce cost and improve quality. To maintain solvency, facilities are looking for methods to reduce overhead and increase profitability. Two key areas of expense, and areas felt to be ripe with opportunity for improvement within hospitals are labor and supply chain. Inefficiency in the deployment of hospital staff has been consistently identified as a primary driver of high cost healthcare. However, if hospitals seek to better manage their labor expense, there is a question of a negative effect on hospital performance. This study examined the association between wage-index-adjusted labor expense per case-mix-index-adjusted discharge and hospital performance in five measurement domains.

Study Design: Due to the high skew of the data, a negative binomial regression was used to examine the potential association between wage-index-adjusted labor expense per case-mix-index-adjusted discharge on five measures of hospital performance. These performance measures were: cost of care, use of evidence-based care, harm (AHRQ patient safety indicators), inpatient mortality, and patient experience (satisfaction survey). The model was evaluated using likelihood ratio and Hosmer-Lemeshow goodness of fit statistics and adjusted for number of licensed hospital beds, teaching status, geographic region, and urban/rural population served.

Population Studied: The analysis included the patient and department level data from 344 acute care hospitals. Data were drawn from clinical, administrative, and operational sources contained within a database maintained by Premier, Inc., Charlotte, NC.

Principal Findings: For all five measures, a one unit increase in hospital performance in each measurement category produced a corresponding case-mix-adjusted labor expense decrease of $264.81 (p>0.001). The primary drivers of this downward trend were compliance with evidence-based care and patient experience. Three of the domains indicated a negative association (use of evidence-based care, inpatient mortality, and patient experience) while cost of care and harm indicated a positive association.

Conclusions: These results demonstrate that quality improvement initiatives can both increase quality of care and reduce labor expense. Although the analysis found a negative association, the high skew of the data indicates that there is high variability between hospitals. Thus, the actual cost savings associated with an increase in hospital performance may vary between facilities.

Implications for Policy, Delivery, or Practice: The future of the U.S. healthcare system depends on reducing cost without negatively affecting care quality. This study shows that initiatives focusing on better management of hospital labor expense can result in both cost savings and improvements in quality.

Poster Session and Number: B, #518

Identifying the Primary Drivers of Healthcare Waste: Potential Savings in Acute Care Facilities

Timothy Lowe, Premier Incorporated; Doug Miller, Premier Inc.; Eugene Kroch, Premier Inc.; John Martin, Premier Inc.; Richard Bankowitz, Premier Inc.

Presenter: Timothy Lowe, Ph.D., M.S.W., Principal Research Scientist, Premier Incorporated, timothy_lowe@premierinc.com

Research Objective: The rapid growth in the cost of providing healthcare services has raised considerable concern among all who are responsible for paying for healthcare. Recent trends indicate U.S. healthcare spending may rise to 20% of gross domestic product by 2019, or roughly $4.6 trillion. Estimates of how much of this expenditure is due to waste — the consumption, spending, or employment of health services without adequate return — range as high as 30%. Premier developed a set of measures targeting healthcare waste to assist healthcare facilities in identifying and reducing waste. This study assessed the amount of potential healthcare waste and its attendant cost in order to identify drivers of waste in the acute care setting.

Study Design: Premier developed 16 measures to assess areas of potential savings for hospitals and health systems spanning clinical, operational, and supply chain domains. Waste was measured in dollars based on comparative cost calculations from the Premier database. Risk adjustment is incorporated through published methodologies or by benchmarking against best-performing peers. As the measures are predominantly high level, there is some overlap between the domains. In order to avoid the bias that would result from summing all...
domains, mean, standard deviation, skew and kurtosis were calculated for each measure.

Population Studied: Assessment of potential waste used the data from 558 acute care hospitals contained within a database maintained by Premier, Inc., Charlotte, NC. Potential waste was assessed using clinical, administrative, operational, and supply chain sources.

Principal Findings: There were 16 measures identified: overuse of blood bank, diagnostic imaging, laboratory services, respiratory therapy, anti-infectives, central nervous system drugs, hospital-acquired complications [AHRQ patient safety indicators], excessive length of stay, ICU length of stay, ICU utilization, readmissions, staffing efficiency [adjusted labor expense per discharge], staffing premium pay [overtime and agency hours], staffing skill mix, contract activation, and purchase order administration. Of the 16 measures, there were eight that had the highest level of waste measured in dollars. These were: staffing efficiency ($5.9M), staffing overtime ($1.2M), staffing skill mix ($1.8M), excessive length of stay ($2.2M), readmissions ($2.3M), overutilization of diagnostic imaging ($682,704), laboratory tests ($902,030), and respiratory therapy ($550,740). All measures had a high positive skew indicating high variability between facilities.

Conclusions: Through this work we were able to identify 16 measures that can be used to evaluate hospital waste. In addition, we found 8 measures that appear to significantly contribute to waste in hospitals. Further refinement of measures in the future will provide a more clear picture of where overlapping measures of waste can be consolidated or refined to improve the accuracy of our measures.

Implications for Policy, Delivery, or Practice: As the healthcare industry adapts to ongoing reimbursement cuts, hospitals must reduce waste across the full spectrum of their operational and clinical practices. Identifying the primary drivers of healthcare waste will assist providers in developing and monitoring targeted programs to successfully reduce waste.

Reducing Healthcare Waste: The Premier Cardiac Device Waste Measures
Timothy Lowe, Premier Incorporated; Choreh Partovian, Yale University Medical Center;

Eugene Kroch, Premier Inc.; John Martin, Premier Inc.; Richard Bankowitz, Premier Inc.

Presenter: Timothy Lowe, Ph.D., M.S.W., Principal Research Scientist, Premier Incorporated, timothy_lowe@premierinc.com

Research Objective: Overutilization, or the provision of medical care with little benefit or where harm outweighs therapeutic benefit, has been posited as a primary driver of high medical cost. Recent studies have identified cardiac procedures as a prime area for cost reduction. This research developed and validated eight measures for assessing the potential savings from reducing cardiac procedure waste.

Study Design: Measure development used a three step approach: literature search, clinical guidelines review, and consultation with physicians and healthcare executives. Potential measures were reviewed by both a clinical panel (two cardiologists and two advanced practice nurses) and an administrative panel (two analysts and a database manager) to assure they were high impact, feasible, and useful/functional. Measures were risk-adjusted using Premier’s CareScience™ methodologies or mean peer value based on MS-DRG assignment. Internal consistency of the measures was evaluated using Cronbach’s alpha and Spearman rank correlations.

Population Studied: Measure development and validation used the data from 261 hospitals participating in a database maintained by Premier. Data were drawn from clinical, administrative, operational, and supply chain sources.

Principal Findings: The development and review process produced eight measures of overutilization: dual-chamber defibrillators, higher cost devices, MRI-compatible pacemakers, drug eluting stents, length of stay, ICU length of stay, and premium pay (overtime and agency hours). Using the QUEST Premier data, we found high variability in resource utilization across facilities. Validation of the measures using item-to-total correlations (range=0.27-0.78), Cronbach’s alpha (0.88), and Spearman rank correlation (0.92), showed high reliability and discriminatory power.

Conclusions: Due to the level of variability observed among hospitals, this study suggests that there is opportunity for facilities to design successful waste reduction programs targeting select cardiac procedures.
Implications for Policy, Delivery, or Practice:
Identification of areas for cost reduction within hospitals and health systems is essential to reigning in excessive healthcare spending and keeping up with the proposed reductions in payments to healthcare providers. With the aging of the U.S. population and attendant increase in the frequency and cost of cardiac procedures, measures, such as these, that identify multiple areas of waste in addressing cardiac procedures waste will be critical in reducing cost while maintaining care quality.

Quality Improvement Implementation in Local Health Departments: Results from the 2010 Profile Study
Huabin Luo, CDC; Sergey Sotnikov, CDC; Anita McLees, CDC; Saira Nawaz, CDC

Research Objective: Over the past decade, quality improvement (QI) has become a major focus in advancing the goal of improving performance of local health departments (LHDs). However, limited data exists on the current status of QI initiatives in LHDs and factors associated with successful QI implementation. The objectives of this study were:
1) To examine the current status of QI implementation projects by LHDs; 2) To identify organizational and community characteristics of LHDs that are associated with their involvement in QI projects.

Study Design: In this study, LHDs’ QI implementation was measured by the number of formal QI projects reported by respondents to the 2010 National Profile of Local Health Departments Study (Profile Study) conducted by National Association of County and City Health Officials. The Profile Study included a sample of 531 LHDs participating in the Module I survey. This module included questions concerning the number of formal QI projects implemented. The Profile Study dataset was merged with the Health Resources and Services Administration’s Area Resource Files and the Association of State and Territorial Health Officials’ 2010 survey. Multiple ordinal logistic regression models were run to estimate LHD organizational and community characteristics associated with formal QI implementation. Analyses were conducted using Stata 11 SVY procedure to account for the complex sampling design. Results were considered significant if p<0.05.

Population Studied: A sample of 531 Local Health Departments from Profile Study.
Principal Findings: The 2010 Profile Study data indicated that about 74% of the LHDs reported implementing 1 or more QI projects, but 7% of them did not implement any of the essential elements for formal QI as recommended. LHDs with large jurisdiction population (above 50,000), more per capita public health expenditure, a full-time director, and with a designated QI staff member were more likely to have implemented more formal QI projects (ps<0.05).

Conclusions: The 2010 Profile Study suggests approximately one-quarter of LHDs surveyed did not report implementing a formal QI project. Additional efforts might be needed to promote QI in LHDs, especially LHDs with limited resources. Targeted investments in QI programs and designation of QI staff are effective strategies to promote QI adoption.

Implications for Policy, Delivery, or Practice:
The validity of formal QI projects definition needs to be established. More research to identify the barriers for successful QI implementation at LHDs is needed.

Temporal Changes and Regional Variation in Prostate Cancer Imaging in a Nation-Wide, Population-Based Cohort Following an Effort to Discourage Inappropriate Use
Danil Makarov, New York University School of Medicine; Stacy Loeb, United States Department of Veterans Affairs and New York University; David Ulmert, Memorial Sloan-Kettering Cancer Center; Linda Drevin, Uppsala University Hospital; Mats Lambe, Karolinska Institutet; Pär Stattin, Umeå University

Research Objective: Encouraging appropriate use of imaging to stage incident prostate cancer is a challenging problem highlighted recently as a Physician Quality Reporting System quality measure and by ASCO in the Choosing Wisely Campaign. Since 2000, the National Prostate Cancer.
Cancer Register (NPCR) of Sweden has led an effort to decrease national rates of inappropriate prostate cancer imaging by disseminating personalized utilization data along with the latest imaging guidelines to urologists in Sweden. We sought to determine the temporal and regional effects of this effort on prostate cancer imaging rates.

**Study Design:** We performed a retrospective cohort study, analyzing imaging utilization over time stratified by clinical risk group (low, intermediate, high) and geographic region. Generalized linear models with a logit link were used to test for time trend.

**Population Studied:** Men diagnosed with prostate cancer from the NPCR from 1998-2009 (N=99,879).

**Principal Findings:** Thirty six percent of men underwent imaging within 6 months of prostate cancer diagnosis. Overall, imaging utilization decreased over time, particularly in the low-risk group, among whom the imaging rate decreased from 45% to 3% (p<0.01), but also in the high risk group, among whom the rate decreased from 63% to 47% (p<0.01). Despite substantial regional variation, all regions experienced significant decreases in prostate cancer imaging (p<0.01).

**Conclusions:** A Swedish effort to provide data on personalized prostate cancer imaging utilization and imaging guidelines to clinicians dramatically reduced inappropriate imaging over a 10-year period, while slightly decreasing appropriate imaging in high-risk patients.

**Implications for Policy, Delivery, or Practice:** These results may inform current efforts to promote guideline concordant imaging, by encouraging policy makers to consider providing incentives for appropriate use as well as disincentives for inappropriate use, in the US and internationally.

**A Tale of Two Pilots: Provider and Staff Perspectives on Care Manager Implementation for Two Regional Health Plan Medical Home Pilots**

Rebecca Malouin, Michigan State University; Heather Howard, PhD, Michigan State University; Amy Faucher, MS, Michigan State University; Seven Mattes, Michigan State University; Martha Callow, Michigan State University

**Presenter:** Rebecca Malouin, PhD, MPH, Assistant Professor, Department of Family Medicine and Department of Pediatrics and Human Development, Michigan State University, rebecca.malouin@ht.msu.edu

**Research Objective:** This study evaluates the effect of two approaches to patient-centered medical home (PCMH) delivery system improvement strategies, specifically the implementation of care managers. Each PCMH strategy focused on improvements in structures and processes within practices with the intention of reducing costs, improving health outcomes, and improving experience. One regional health insurer in New York provided health plan staff as care managers to work in the practice one or two days a week with the patients of that health plan. The other regional health insurer, in Michigan, provided grants to the practices to hire a care manager and utilize them according to individual practice needs. The objective is to examine, from the perspective of providers, staff, and health plan administrators, the effectiveness of two different strategies for implementing care managers in primary care practices.

**Study Design:** 100 key informant interviews and 23 focus groups were conducted with practices from April to June 2011 and April to June 2012, respectively. Practices were reimbursed $100 for each interview and $500 for each focus group. All interviews and focus groups were transcribed and then coded and analyzed by multiple investigators using NVivo qualitative analysis software.

**Population Studied:** Interview participants, in addition to health plan staff, most often included the physician champion, practice administrator, and care manager, while focus groups were conducted solely with practice staff.

**Principal Findings:** The care managers in New York practices were nurses provided by the health plan, who worked in the practice one or two days a week with patients of that health plan. Some practices were initially leery of having a health plan employee in their practice. These care managers helped to coordinate patient care by, for example, following-up with patients after hospitalizations and specialist visits.

The care managers in Michigan were hired by each practice, using grant money provided by the health plan, and came from different backgrounds, such as nursing, social work, and
kinesiology. These care managers were practice employees and could see all practice patients. Many practices were not sure how to implement them in their practice, as the need was so great and integrating them into existing practice structures was challenging. Following the end of the pilot, many of the New York practices continue to access their care managers from the health plan. However, in Michigan some of the practices have been unable to sustain support for their care managers following the loss of the grant money.

Conclusions: The implementation and integration of new roles, such as care managers, presents an area of particular challenge when undergoing practice transformation. Primary care practices can benefit from the use of a care manager, but practices may want to seek out advice from other practices or learning networks on the best practices for hiring, integrating, and sustaining a care manager.

Implications for Policy, Delivery, or Practice: Planning for the type of individual that would best serve the practice and patients, how they will be integrated into the current practice structure, and how they will be sustained financially, could help maximize the benefits that can come from having a care manager.

The Association between Patient Preferences for Colorectal Cancer Screening and Screening Receipt in the VA

Kathryn Martinez, University of Michigan; Bruce Ling, MD, MPH, VA Pittsburgh Healthcare System; Sally Vernon, PhD, University of Texas School of Public Health; Melissa Partin, PhD, University of Minnesota; Sarah Hawley, PhD, MPH, Ann Arbor VA/University of Michigan, Division of General Medicine

Presenter: Kathryn Martinez, PhD, M.P.H., Postdoctoral Fellow, Division of General Medicine, University of Michigan, katiemartinez@gmail.com

Research Objective: Incorporation of patient preferences is a critical component of patient-centered care. Despite relatively high colorectal cancer (CRC) screening rates within the VA, adherence with screening among some subgroups of veterans remain suboptimal. Preferences for screening modality (colonoscopy vs. fecal occult blood testing [FOBT]) vary, and may influence receipt of screening. The objective of this study was to evaluate the relationship between stated preference for CRC screening modality and adherence to CRC screening type among veterans.

Study Design: This study used data from an intervention trial of a preference-tailored decision tool aimed at increasing CRC screening adherence (intervention data not reported). Veterans’ preferred screening modality (colonoscopy vs. FOBT) was obtained following completion of the decision tool. Screening outcome was assessed by chart review six months later. We utilized multinomial logistic regression to examine the relationship between stated preference for CRC screening modality (colonoscopy vs. FOBT) and screening outcome (non-adherent, adherent with colonoscopy, adherent with FOBT) at six months follow-up. We included age, race, education, income, marital status, and study arm as control variables in the analyses.

Population Studied: Veterans, aged 50 to 77, due for CRC screening, with a scheduled primary care appointment, at two VA health systems (N=374).

Principal Findings: Thirty-nine percent of veterans were adherent with CRC screening at the six month follow-up. Among the 258 veterans in our sample stating a preference for FOBT, 64 percent were non-adherent with any screening modality at six months and 28 percent were adherent with FOBT. Of the 114 veterans who stated a preference for colonoscopy, 56 percent were non-adherent at follow-up and 33 percent were adherent with colonoscopy. At six months, ten percent of veterans in this sample who preferred colonoscopy at baseline were adherent with FOBT, while 8 percent of veterans preferring FOBT were adherent with colonoscopy. In the adjusted multinomial model comparing adherence to either colonoscopy or FOBT to non-adherence, veterans preferring colonoscopy versus FOBT were significantly more likely to be adherent with colonoscopy than to be non-adherent with screening overall (OR=5.15 p=0.001), and veterans preferring colonoscopy over FOBT at baseline were less likely to be adherent with FOBT (versus non adherent) at follow-up (OR=0.43 p=0.014). In the model with adherence to FOBT as the base category, veterans who preferred colonoscopy over FOBT were more likely to be adherent with colonoscopy versus FOBT at follow-up (OR=11.8 p=0.001). Veterans who preferred colonoscopy over FOBT were more likely to be
non-adherent at six months than adherent with FOBT (OR=2.30, p=0.014). No other covariates were significantly associated with adherence in either model.

**Conclusions:** In our sample of veterans eligible or overdue for CRC screening, overall screening adherence at the six month follow up point was low. Yet among those who got screened, there was a strong association between preference for screening modality at baseline and receipt of the same test six months later.

**Implications for Policy, Delivery, or Practice:** Understanding and acknowledging patients' preferences for a specific CRC screening modality may translate to higher CRC screening adherence in various primary care settings and, ultimately, be necessary for improving provision of patient-centered care.

**Funding Source(s):** VA

**Establishing the Overall Health Status of Low-Income Children Enrolled in Head Start Programs in Boston, Massachusetts from 2011-2012**

Karine Martirosyan, Action for Boston Community Development, Inc; Karen Hampanda, University of Colorado Denver; Jennifer Pawson, Action for Boston Community Development, Inc.

**Presenter:** Karine Martirosyan, M.D., M.P.H., Director, Head Start Health Services, Head Start and Children’s Services, Action for Boston Community Development, Inc, karine.martirosyan@bostonabcd.org

**Research Objective:** To establish the most prevalent morbidities impacting the health of children 0 to 5 years of age enrolled in Head Start programs and the overall health status of the population.

**Study Design:** A Cross sectional analysis of data from the Action for Boston Community Development (ABCD) Head Start Promis Cleverex V5.16 database was conducted to determine the prevalence of specific morbidities among low-income children in Head Start programs. Descriptive statistics were calculated based on the child’s diagnosis, including asthma, allergies, eczema, optical problems, and heart conditions, in the Head Start database. The prevalence of dental caries and learning disabilities were not included in this analysis since previous research has focused specifically on these topics.

**Population Studied:** Children ages 0-5 years enrolled in Head Start or Early Head Start programs from 9/1/2011 to 5/31/2012. All children meet the federal guidelines for living at or below the poverty level. A total of 2,939 children’s records were included in the analysis.

**Principal Findings:** Of 2,939 children enrolled in ABCD Head Start programs, 548 (18.6%) were diagnosed with asthma, 348 (11.8%) with allergies and 68 (2.3%) with eczema. Additionally, 71 (2.4%) children have optical problems corrected with glasses and 16 (1%) have a diagnosed heart condition, such as heart palpitations.

**Conclusions:** The most common health conditions in this group were found to be asthma, allergies and vision problems. The study demonstrates that children in Head Start programs in Boston often have chronic health conditions that have the potential to impact their ability to learn in school and function in their daily lives.

**Implications for Policy, Delivery, or Practice:** This study provides a basis for initiating or continuing key services to the population of low-income children in Boston. There is need for families with young children to receive health education, particularly related to asthma and allergies, given the high prevalence of these conditions. Furthermore, the high rate of asthma in Head Start children indicates the need for assistance in providing asthma friendly homes and schools throughout Boston.

**Trends in Prevalence of Asthma Diagnosis in Children Enrolling in Head Start and Early Head Start Programs from 2009 to 2012 in Boston, Massachusetts**

Karine Martirosyan, Action for Boston Community Development, Inc; Karen Hampanda, University of Colorado Denver; Jennifer Pawson, Action for Boston Community Development, Inc.

**Presenter:** Karine Martirosyan, M.D., M.P.H., Director, Head Start Health Services, Head Start and Children’s Services, Action for Boston Community Development, Inc, karine.martirosyan@bostonabcd.org

**Research Objective:** To establish trends in childhood asthma diagnosis among the Head Start and Early Head Start population in Boston, Massachusetts from 2009 to 2012.
Meeting the Oral Health Needs of Homeless Children enrolled in ABCD Head Start programs in Boston, Massachusetts: a Look at Their Oral Health Status, Caries Experience, and Dental Services Received through On-Site Mobile Dental Care 2010-2011

Karine Martirosyan, Action for Boston Community Development, Inc; Karen Hampanda, University of Colorado Denver; Kathy Lituri, Boston University Goldman School of Dental Medicine; Mark J. Doherty, DentaQuest Institute

Research Objective: To study the oral health needs of homeless children enrolled in ABCD Head Start programs in Boston, Massachusetts.

Study Design: A Cross sectional analysis of data from the Action for Boston Community Development (ABCD) Head Start Promis Cleverex V5.16 database and children's dental records was conducted to determine the prevalence of oral health problems among homeless in ABCD Head Start programs. We studied 31 homeless children who had a dental exam from an on-site mobile dentist during the 2010-2011 school year. We compared their outcomes with dental health status of 62 low-income housed children enrolled in ABCD Head Start program during the same period.

Population Studied: Homeless and housed low-income children 3 to 5 years old enrolled in ABCD Head Start programs in Boston, Massachusetts during the 2010-2011 school year. The total sample size is 93 Head Start children (31 homeless and 62 low-income housed children).

Principal Findings: Only one of the 31 homeless children had a dental home prior to enrollment in Head Start; over 96% of children had no dental home. All of the homeless children (N=31) in the study had health insurance. Thirty homeless children (96.8%) have publically-funded health insurance with full dental coverage. In comparison, approximately half of housed Head Start children had dental homes prior to enrollment and 92% rely on publically-funded health insurance (N=62). Homeless Head Start children have statistically significant more dental caries (p>0.010); they

Study Design: A trend study design using cross-sectional data from two school years (2009-2010 and 2011-2012) was employed to examine the prevalence of asthma diagnosis among Head Start and Early Head children. Cross-sectional data was collected using ABCD Head Start Promis Cleverex V5.16, the database for all enrolled children in Boston Head Start programs. Using calculated descriptive statistics with the outcome of asthma diagnosis, prevalence trends from the two school years and two programs were compared.

Population Studied: Children 0 to 5 years old enrolled in either Head Start (3-5 years old) or Early Head Start (0-3 years old) programs from 9/1/2009-5/31/2010 and 9/1/2011-5/31/2012. The total sample size is 3,941 Head Start children.

Principal Findings: In the 2009-2010 school year, of the 1,002 children enrolled in ABCD Head Start programs, 177 (17%) were diagnosed with asthma: 172 (17.8%) in Head Start and 53 (20.1%) in Early Head Start. In the 2011-2012 school year, of the 2,939 children enrolled in ABCD Head Start programs, 548 (18.6%) were diagnosed with asthma: 522 (19%) in Head Start and 35 (13.9%) in Early Head Start.

Conclusions: Compared with the 2009-2010 school year, overall asthma prevalence in children enrolling in ABCD Head Start programs increased by 1.6% in the 2011-2012 school year. Among 3-5 year olds, asthma diagnoses increased 1.2%. However, asthma in the younger children deceased over 6%.

Implications for Policy, Delivery, or Practice: Head Start children have much higher rates of asthma than the national prevalence. This follows nationwide trends in health disparities indicating that lower socioeconomic status (SES) children suffer from worse health outcomes. There is an urgent need to address the environmental exposure and other social determinants of health that may be attributable to this difference. More research is needed to fully understand the increase in asthma diagnoses among older Head Start children, but the dramatic decrease among younger Head Start children.

Funding Source(s): No Funding

Poster Session and Number: B, #526
are 3.1 times more likely to have caries than housed children. Prevalence of untreated caries is 35.5% in homeless Head Start children and 11.2% in low-income housed Head Start children. Over 41% of homeless children have caries experience, defined as at least one tooth with an untreated cavity, a filling, or a missing permanent molar. In addition, there was one child with a broken tooth from trauma that needs to be monitored by a dentist for possible infection. Of the 31 children that were seen by the mobile dentist at Head Start, six (19%) were referred for treatment to a community dental clinic (see Chart 1). 30 children (97%) received fluoride varnish; 26 children (83.9%) received sealants on multiple teeth; and 2 children (7%) received fillings for existing caries provided by the on-site mobile general dentists with experience in pediatrics.

**Conclusions:** Homeless children in Head Start are less likely than housed children to have a dental home prior to enrollment. The vast majority of Head Start children rely on publically funded health insurance to pay for their dental care, especially if the family is homeless. The children in this study were from 3-5 years old and almost none of the homeless children had seen a dentist prior to the mobile dental exam at Head Start. This study has also found that homelessness increases children’s risk of having poor oral health.

**Implications for Policy, Delivery, or Practice:** There is an urgent need to create earlier preventative oral health interventions for homeless families to prevent dental caries and decay from developing in homeless preschool-age children. The on-site mobile dental program is essential for providing comprehensive dental care to homeless children. However, more emphasis should be placed on helping homeless families establish dental homes in order for their children to receive on-going oral health care after they leave Head Start. However, enrolling homeless children in center based preschool programs such as Head Start is an important step to help this vulnerable group of children access comprehensive dental services.

**Poster Session and Number:** B, #527

**Organizational Predictors of Coordination in Inpatient Medicine**

**Presenter:** Nathalie McIntosh, Boston University, mcintnm@gmail.com

**Research Objective:** As the care of hospitalized patients becomes more complex, intraprosessional coordination among nurses and among physicians, and interprofessional coordination between these groups is likely to play an increasingly important role in the provision of hospital care. The purpose of this study was to identify the independent effects of organizational factors on provider ratings of overall coordination in inpatient medicine.

**Study Design:** This was a cross-sectional, descriptive study. Primary data were collected between June 2010 and September 2011 through surveys of inpatient medicine nurse managers, physicians, and chiefs of medicine at 36 Veterans Health Administration (VHA) medical centers. Secondary data from the 2011 VHA national survey of nurses were also used. Individual-level data were aggregated and analyzed at the facility level. Multivariate linear regression models were used to assess the relationship between organizational factors and provider ratings of overall coordination in inpatient medicine.

**Population Studied:** Inpatient medicine nurses, nurse managers, attending physicians, and chiefs of medicine at 36 VHA medical centers.

**Principal Findings:** Organizational factors that were common across models and associated with better provider ratings of overall coordination in inpatient medicine included: provider perceptions that the goals of senior leadership are aligned with those of the inpatient service and that the facility is committed to the highest patient care; having resources and staff that enable clinicians to do their jobs; and use of strategies that enhance interactions and communication among and between nurses and physicians.

**Conclusions:** Alignment of the goals of senior leadership with those of the inpatient service, facility commitment to the highest patient care,
having adequate resources and staff enabling clinicians to do their jobs, and the use of strategies that enhance intra- and interprofessional interactions and communication are associated with higher provider perceptions of overall coordination.

**Implications for Policy, Delivery, or Practice:**
To improve intra- and interprofessional coordination, and consequently patient care, facilities should consider: making patient care quality a more important strategic organizational priority; ensuring that providers have the staffing, training, supplies and other resources they need to do their jobs; and implementing strategies that improve interprofessional communication and working relationships, such as multidisciplinary rounding.

**Asthma-Related Healthcare Utilization and the Effects of Direct to Consumer Advertising among White and Black Medicaid Children**

Luceta McRoy, University of Alabama at Birmingham; Meredith Kilgore, Ph.D., University of Alabama at Birmingham; W. David Bradford, Ph.D., University of Georgia; Robert Weech-Maldonado, Ph.D., University of Alabama at Birmingham

**Presenter:** Luceta McRoy, Ph.D., Health Administration, University of Alabama at Birmingham, lmcroy@uab.edu

**Research Objective:** The increasing burden of asthma affects approximately 40 million Americans. The prevalence is higher among minorities and those from low income families resulting in higher levels of asthma-related hospitalizations and emergency department visits. The purpose of this study is to examine the effects of DTCA on asthma-related hospitalizations and emergency department visits.

**Study Design:** In this study we combined Medicaid administrative data with national advertising data on asthma medication expenditures from 1999 to 2002. Dependent variables are asthma-related hospitalizations measured as the number of hospital visits per year and asthma-related emergency department visits measured as the number of emergency department visits per year. The main independent variable is DTCA measured as advertising expenditure by county over the study period. Control variables were: race measured as whites and blacks; age measured as year at baseline; and gender measured as male and female. We used a series of logistic regression with population average effects for the analysis.

**Population Studied:** The study included Medicaid children between the ages of 5 and 18 who had an asthma diagnosis at any time during the study period 1999 to 2002.

**Principal Findings:** Increased spending of DTCA is associated with a decrease in emergency department visits (p <.05). Among black children, emergency department visits decreased significantly (p<.05). There was no significant effect on white Medicaid children. Increased DTCA spending is associated with an increase in asthma-related hospitalizations among white Medicaid children (p <.05) and although asthma-related hospitalizations decreased among black children the effects were not significant

**Conclusions:** DTCA spending has some effect on health utilization. The effects vary significantly among black and white Medicaid children for emergency department visits and hospitalizations.

**Implications for Policy, Delivery, or Practice:**
With increased debates on the benefits of DTCA, policy makers should consider that DTCA could assist in improved health outcomes and decreased health utilization. Further consideration should be given to the role of DTCA in helping to reduce the burden of asthma and health-disparities.

**Chronic Health Conditions Prior to Entry into Medicare Fee-for-Service or Medicare Advantage**

Eric Miller, National Center for Health Statistics; Sandra L. Decker, National Center for Health Statistics; Jennifer D. Parker, National Center for Health Statistics

**Presenter:** Eric Miller, Ph.D., Senior Research Fellow, National Center for Health Statistics, bwe6@cdc.gov

**Research Objective:** Although studies have examined the health conditions of Medicare beneficiaries enrolled in Medicare managed care [Medicare Advantage (MA)] versus traditional fee-for-service (FFS), there is little information on the health of beneficiaries prior to enrollment and if these characteristics have changed as
Medicare policies have changed. Using National Health Interview Survey (NHIS) data linked to Medicare enrollment data, we examined if individuals who initially enroll in MA rather than FFS at age 65 have fewer health conditions or better overall health (i.e. positive selection) and if the degree of positive selection into MA changed between 2000-2009, particularly beginning in 2006 when drug coverage become available for FFS enrollees.

**Study Design:** We used self-reported health data from the 1997-2005 NHIS linked with Medicare enrollment data from 2000-2009. The analysis was restricted to survey participants aged 60-64 years in the NHIS with Medicare enrollment data when they aged into the program at 65. Enrollment into MA was defined as any MA enrollment during the first 6 months of entitlement. We compared self-reported health status and health conditions for MA and FFS enrollees overall and within two time periods (2000-2005 and 2006-2009). Health conditions included diabetes, hypertension (if diagnosed on more than one visit), cardiovascular disease [(CVD); including myocardial infarction, stroke, angina, hypertension, and coronary heart disease], cancer (excluding non-melanoma skin), asthma, and also the total number of conditions (0,1,>1). Multivariable logistic regression models were used to calculate the associations of each condition with MA enrollment controlling for sex, race/ethnicity [white non-Hispanic, black non-Hispanic (BNH), Hispanic, other], education [up to high school (HS) degree, >HS coursework] and region of residence in the U.S.. We also examined potential changes in enrollment patterns from 2000-2005 to 2006-2009 by including an interaction term for each condition and a dichotomous variable for time-period. We used a Satterthwate adjusted F test (p=0.05) to determine statistical significance. Estimates were weighted and standard errors calculated using SUDAAN v11.0 to account for the complex survey design.

**Population Studied:** Sampled adults aged 60-64 years in the 1997-2005 NHIS linked with 2000-2009 Medicare enrollment data.

**Principal Findings:** Data were available from 6,254 NHIS participants who aged into Medicare between 2000 and 2009. A significantly higher percentage of MA beneficiaries were female (p<0.01), of lower education level (p=0.04), or of Hispanic ethnicity (p<0.01) compared to FFS. Enrollment in MA increased from 10.0% during 2000-2005 to 19.1% during 2006-2009 (p<0.01).

There were no statistically significant associations between MA enrollment and self-reported health or any of the chronic conditions examined. Results were similar after adjusting for demographic characteristics in multivariable logistic regression models. When examining potential changes by time period with an interaction term, there were no significant changes in enrollment patterns for any of the chronic conditions.

**Conclusions:** We found no evidence of positive selection in MA by chronic health conditions we were able to examine and no evidence that enrollment patterns have changed between 2000 and 2009.

**Implications for Policy, Delivery, or Practice:** We found no evidence of positive selection into MA for new Medicare enrollees.

**Healthy TEAM Healthy U: An effective Worksite Wellness Program**

**Esther Moe, Oregon Health and Science University**

**Presenter:** Esther Moe, Ph.D., M.P.H., Research Assistant Professor, Medicine, Oregon Health and Science University, moe@ohsu.edu

**Research Objective:** To assess the effectiveness of a team-based worksite wellness program, designed to improve exercise and nutrition behaviors among employees at the Oregon Health & Science University (OHSU).

**Study Design:** All OHSU benefit-eligible employees were offered the opportunity to participate in the Healthy TEAM Healthy U (HTHU) wellness program, with an inducement of reduced insurance premiums and up to two hundred dollars as a financial bonus. HTHU is a scripted, team-centered curriculum with a curriculum and web component for tracking participation and points for achieving weekly goals and completing on-line activities and additional learning opportunities. Teams of 4-6 co-workers met weekly for twelve, 30-minute sessions. A Team Leader curriculum instruction manual was rotated among participants who use a workbook and ancillary wellness guide. Height, weight, resting blood pressure measurements and completion of pre and post nutrition and physical activity behavior surveys and related health knowledge were assessed among consented volunteers.
**Population Studied:** OHSU employees (n=852) involved in the first year of the HTHU wellness program responded to survey questions at both pre and posttest. Of those, 253 participants also had physical measurements assessed.

**Principal Findings:** Overall, there was a significant decrease in systolic and diastolic blood pressure, with greater reductions, nearly 10 mm Hg and 5 mm Hg among those with systolic (> 135 mm Hg) and diastolic (> 85 mm Hg) blood pressure, respectively. Although the overall BMI for those measured did not decrease, among those with a higher pre-intervention BMI (> 25), there was a significant BMI reduction (p<0.0001). Self-reported fruit and vegetable intake increased overall; however the greatest increase (increase of 1.68 servings/day) was among those with pre-test intake of less than < 3 servings/day (p<0.0001). There was a significant increase of 2 days/week of intense physical activity of the HTHU participants (p<0.0001) for participants who initially reported lower levels of weekly physical activity. Indices of past month depression among those reporting being initially depressed improved (p<0.0001) (pre=5.29, post 3.37). The number of HTHU participants who missed work due to any medical reason at baseline significantly decreased their report of missing days of work after completion of the HTHU program (p<0.0001). Knowledge of the health benefits of fruits and vegetables also revealed improvement.

**Conclusions:** The Healthy TEAM Healthy U employee wellness program changed objective health measures (blood pressure and BMI), fruit and vegetable intake and physical activity. The impact of coworkers positively influencing health behaviors was evident by a significant increase in reporting that co-workers “now remind me to eat healthier” (pretest=3.34, posttest 4.44 out of 5). Additional analyses concerned with return on investment, compared to a comparable control group will determine the medical costs as compared to a similar aged and sex-based cohort for all participants (n=2786).

**Implications for Policy, Delivery, or Practice:**
A team-based workplace strategy that encourages healthy diet and physical activity can improve healthy behaviors and improve objective health measures.

**Child and Adolescent Healthcare Quality Disparities: Findings from the National Healthcare Quality and Disparities Reports**

**Study Design:** Child and adolescent healthcare measures were extracted from the NHQR-DR database and analyzed. The measures are organized into child and adolescent age groups (0-17) stratified by race/ethnicity, education, income, insurance and urban vs rural location. The significant differences between populations for most recent year and trends over time (at least 3 data years) are tested for statistical significance at alpha=0.05, using two-tailed test, and a minimum relative difference of 10 percent between the comparison and reference group.

**Population Studied:** United States child and adolescent population

**Principal Findings:** From 2007 to 2009, the percentage of Non-Hispanic Black live-born infants with low birth weight (less than 2500 grams) was higher than for Non-Hispanic White infants. In 2007, infant mortality per 1000 live births was higher for American Indian or Alaska Native and Black infants than for White infants. Asian or Other Pacific Islander infants had lower mortality rates than did White infants. From 2001 to 2005, maternal deaths per 100 000 live births were higher for mothers with only a high school education than those with at least some college education. From 2002 to 2009, children ages 2-17 with public insurance and those without insurance were less likely to have a dental visit than those with private insurance. From 2002 to 2009, the percentage of children ages 2-17 given advice to exercise was significantly less
for those without insurance compared to those who have private insurance.

From 2002 to 2009, the percentage of children ages 2-17 given advice about healthy eating who live in small metro and non core areas was significantly lower compared to those who live in large fringe metro areas. In 2009 and 2010, adolescent females ages 13 to 15 from middle income families were less likely to receive 3 or more doses of HPV vaccine than females from high income families. In 2009 adolescents ages 10 to 17 from middle, low and poor income families were less likely to receive a well visit in the last 12 months than those from high income families.

**Conclusions**: The results from this evaluation show that disparities in the quality of healthcare services are experienced by Non-Hispanic Black, American Indian or Alaska Native children and those from lower socioeconomic strata across a range of healthcare quality measures.

**Implications for Policy, Delivery, or Practice**: Focused policies and research that can identify specific ways to improve the isolated areas of concern identified from this assessment, can greatly improve the quality of life and health of disadvantaged children in the United States. For example, there have been successful, interventions, such as the Nurse-Family Partnership, aimed to educate mothers from lower income households to improve pregnancy outcomes. Other initiatives focusing on child and adolescent health include the Carilion Clinic Dental Care-Pediatrics, which is a hospital-based outpatient clinic providing comprehensive dental care for children without insurance.

**Community Health Center Expansion: Roles of Nurse Practitioners, Physician Assistants, and Clinical Nurse Midwives**

Perri Morgan, Duke University Medical Center; Christine Everett, University of Wisconsin-Madison; Esther Hing, Center for Disease Control

**Presenter**: Perri Morgan, M.S., P.A., Associate Professor, Community and Family Medicine, Duke University Medical Center, perri.morgan@duke.edu

**Research Objective**: Since their creation as part of the War on Poverty in the 1960’s, Community Health Centers (CHCs) have filled an important role in providing health care to underserved populations. Recent infusions of federal support have expanded this role, and demands on CHCs are expected to grow with full implementation of the Affordable Care Act. Nonphysician clinicians have been used extensively in CHCs for decades, but their use has increased, with nurse practitioners (NPs), physician assistants (PAs), and nurse midwives (CNMs) providing 30% of CHC visits in 2006-07. This project examines the roles of NPs, PAs, and CNMs in CHCs from 2006-2010

**Study Design**: This study analyzes annual cross-sectional restricted survey data National Ambulatory Medical Care Survey (NAMCS) Community Health Center strata from 2006-2010. We describe provider mix in relation to clinic characteristics (size and major sources of financial support), estimate number of weekly clinical encounters by provider type, and compare nonphysicians with physicians with regard to patient characteristics and patient care attributes. We also examine trends in skill mix use in CHCs. Survey weights are used to produce national estimates.

**Population Studied**: The NAMCS CHC sample is a representative national sample of CHC providers and patients nationally.

**Principal Findings**: The sample included CHC visits to 1186 physicians, NPs, PAs, and CNMs, representing a national average estimate of 150,100 providers per year. Of the 1186 providers, 68% were physicians, 21% were NPs, 9% were PAs, and 2% were CNMs. The physician to nonphysician ratio did not change significantly over the five years studied. Nationally, there were, on average, 36, 469, 000 visits to CHCs per year over the five year period. NPs, PAs, and CNMs provided 36.8% of these visits. Analyses of patient care characteristics of CHC physicians, NPs, PAs, and CNMs are in progress and will easily be complete by 2/28/13.

**Conclusions**: Results provide detailed information about staffing patterns and deployment of nonphysician clinicians in a setting in which they comprise a large portion of providers and care for populations that carry a large burden of chronic disease.

**Implications for Policy, Delivery, or Practice**: This project is relevant to pressing current issues related to the success of healthcare reform, access to care for vulnerable populations, costs of healthcare, and expected workforce shortages. The Affordable Care Act stipulates reforms that require a strong primary care system, but the adequacy of the U.S.
primary care workforce is in doubt. This project describes a system that embodies a potential solution to this problem—staffing models that utilize high proportions of nonphysicians in primary care settings. Since nonphysicians cost less to employ than do physicians, results of this analysis also have implications for addressing costs associated with provider staffing. This information will be useful to health care administrators and workforce planners in other settings as they face the difficulties of providing care to growing numbers of Americans with chronic disease and seek solutions to anticipated workforce shortages.

**Funding Source(s):** Other, Physician Assistant Education Association

**Principal Findings:** The key informants endorsed the value for CER D&I via the CTSA consortium. Some institutions were actively engaged in D&I activities. However, many highlighted their perception of the limited investment committed by CTSAs to this effort. Other barriers to CER D&I included: lack of institutional awareness, limited capacity of researchers with appropriate D&I expertise, lack of established D&I methods, confusion about what CER is (especially on the part of stakeholder partners). Institutions that were conducting CER D&I activities involved specific research groups in partnership with health systems or as a component of quality improvement initiatives. The audience for CER D&I was primarily healthcare providers within each CTSA’s community network. Few CTSAs engaged in systematic dissemination of CER evidence from landmark clinical trials or of resources developed by national organizations such AHRQ. Dissemination techniques often lacked sophistication and involved traditional methods, including presentations at national meetings, publications, and local seminars. Unless individual investigators had received funding to conduct a D&I study with specific outcome measures, D&I evaluation at the CTSA organizational level largely consisted of tracking publications and scientific presentations.

**Conclusions:** The CTSA consortium is positioned to contribute to the expanding national CER D&I infrastructure. However, greater understanding of D&I best practices and emphasis on the value of D&I (including financial support) are needed to address institutional barriers.

**Implications for Policy, Delivery, or Practice:** Two opportunities emerged to improve national D&I of robust CER evidence using the CTSA
Cost-Effectiveness of a Multidisciplinary ED Care Coordination Program Using a Regional Hospital Information System

Sean Murphy, Washington State University; Darin Neven, Providence Sacred Heart Medical Center & Children’s Hospital

Research Objective: A small proportion of individuals often consume a relatively-large quantity of emergency-department (ED) resources. Frequent and unnecessary utilization of the ED is likely a sign of a serious latent patient issue, and negatively impacts hospitals, providers, third-party payers and society. Therefore, policymakers have been focused on reducing non-urgent ED expenditures. For example, the Washington State Health Care Authority (HCA), proposed a policy to deny reimbursement for “not-medically-necessary” ED visits made by Medicaid beneficiaries. The policy was suspended by the legislature, and replaced by one allowing hospitals to apply best practices for reducing non-emergent ED visits; however, the HCA can revert to the previous plan if an adequate reduction in ED expenditures is not achieved. This paper assessed the cost effectiveness of a multidisciplinary-ED-care-coordination program in Spokane, Washington. The program is somewhat unique in that not only are individualized-ED-care guidelines created by a committee of experts, but it also contains a regional-hospital-information system capable of sharing care plans with other cooperating EDs.

Study Design: This is a two-year retrospective pre-post analysis. To determine whether the program was cost-effective from the hospital’s perspective for both relatively-low and -high frequent-users, the sample was split into two groups, those with 3-11 ED visits in the 365 days preceding enrollment (frequent users), and those with more than 11 visits (extreme users). Differences in ED visits, treatment costs, cost-per-visit and net-income were tested using nonparametric bootstrapping techniques. Regression towards the mean (RTM) was controlled for using an adjusted measure of change.

Population Studied: Patients eligible for the study were at least 18 years of age, and had complete data for, and at least 3 visits to the ED in, the year prior to their induction into the program.

Principal Findings: There were significant decreases in ED visits and direct-treatment costs leading to hospital cost-savings and increased net-income for both frequent and extreme users. The results further indicated that fewer resources were utilized per visit, and that the cost of enrolling a patient could increase approximately eightfold before the extreme-users’ direct-treatment costs would not be significantly lower post-enrollment, while the cost for frequent users could double. RTM does not appear to be an issue.

Conclusions: The program analyzed here appears to be cost-saving from the hospital’s perspective for both frequent and extreme ED users, but especially for the latter group. We speculate that fewer resources were utilized per visit due to ED physician being better informed by the ED care guidelines.

Implications for Policy, Delivery, or Practice: ED-care-coordination programs would appear to be an efficient use of both hospital and public resources. In addition to our findings, a prior analysis by the HCA of Medicaid beneficiaries enrolled in the program indicated a cumulative 44% reduction in ED visits across all EDs in Washington. This is indicative of the potential associated with combining an ED-care-coordination program with a patient-information-exchange system. The fact that program-staff members ensure each patient has a primary-care physician who helps develop their care guidelines, suggests that care for non-emergent conditions is accessible. Finally, a cost-analysis suggested economies-of-scale, implying that one large program per area would be efficient.

Poster Session and Number: B, #534

Funding Source(s): Other, Washington State University Spokane Office of Research

Poster Session and Number: B, #535
Research Objective: Few studies have examined the potential connection between violence and prescription opioid abuse. A pharmacological explanation for the observed positive effect of opioid abuse on violence does not appear to exist. However a number of other explanations have been posited. This study attempts to shed additional light on the latent factors linking opioid abuse and adolescent violence, while controlling for the prescription-opioid source (prescribed or diverted) and other substances. This study is one of the first, if not the first, to distinguish between adolescents who misused their own prescriptions and those who obtained the medications from alternative sources, in this context. A secondary objective was to compare the estimated effects of opioid abuse on violence to those associated with other substances. Developing a better understanding of the connection between opioid abuse and violence is critical, given (a) the highly addictive nature of opioids; (b) the negative consequences associated with their abuse; and (c) the drastic increase in prescriptions since the late 1990s.

Study Design: The model was estimated using full information maximum likelihood within a structural equation modeling framework to account for missing data.

Population Studied: The study population was Washington State public-school students. The study sample consisted of a simple random sample of Washington students who completed the 2008 Healthy Youth Survey.

Principal Findings: Diverted- and own-prescription opioid abuse among adolescents were evidenced to be predictive of the likelihood of violent thoughts and subsequent violent behavior. Own-prescription abuse had the largest effect on the likelihood of violence, followed closely by diverted-prescription and alcohol abuse. Additional substances that appeared to increase the likelihood of violence were inhalants, marijuana, and nicotine.

Conclusions: We add to the literature by drawing inferences on the latent factors linking opioid abuse and adolescent violence. By incorporating both intent and subsequent behavior, our operationalization of violence reduces the likelihood that individuals simply found themselves in a violent situation. Furthermore, we categorized opioid abusers according to whether they were misusing their own, or a diverted-opioid prescription, and found frequency of abuse to be positively associated with the likelihood of engaging in violence regardless of the source. The positive and significant effect of own-prescription abuse on violence suggests that the link is not merely the result of substance abusing patients committing crimes to pay for their drugs.

Implications for Policy, Delivery, or Practice: A connection between opioid abuse and violence adds to the staggering economic costs associated with the former. The fact that this outcome was observed among youths abusing their own prescriptions is further cause for concern given the 402% increase in opioid sales between 1997 and 2007. Moreover, given the highly addictive nature of opioids, many adolescents will continue to abuse them into adulthood. Our finding that the prescribing of high doses of opioids over time could be contributing to violence among adolescents indicates that opioid abuse is a potentially modifiable risk factor. Therefore, it is clear that additional resources should be allocated to strategies aimed at reducing misuse and overprescribing of opioids.

Measuring Service Needs for Children with Complex Medical Conditions Using the Kids Intensity of Care Survey

Ann-Margaret Navarra, Columbia University; Linda Mosiello RN, MS, Sunshine Children’s Home and Rehabilitation Center; Laura Schneider, RN, MSM, Sunshine Children’s Home and Rehabilitation Center; Mary Keenan, MS, Sunshine Children’s Home and Rehabilitation Center; Elaine Larson, RN, PhD, CIC, FAAN, Columbia University School of Nursing

Presenter: Ann-Margaret Navarra, D.Phil., Post Doctoral Research Fellow, School of Nursing, Columbia University, ad66@columbia.edu
Research Objective: Children with complex medical conditions (CMC) have substantially increased in number over the past decade resulting in disproportionate utilization of healthcare resources. Yet severity of illness and intensity of service needs are typically quantified using taxonomies designed for adult patients. The ability to estimate service needs for children with CMC using a psychometrically sound pediatric measure is needed to better predict allocation of healthcare resources. The aims of this pilot study were to test the Kids Intensity of Care Survey (KICS) tool and assess the correlation of the KICS with the case mix index (CMI) in children with CMC.

Study Design: This study was part of a larger parent project designed to improve infection prevention practices in three New York area pediatric long-term care (LTC) facilities, and was funded by the Agency for Healthcare Research and Quality (AHRO - 1R01HS021470). The KICS was developed by content experts specializing in pediatric LTC. It is a 33 item tool designed to measure and predict intensity of care in five categories (basic, skilled and restorative nursing care, medication administration and need for specialty care clinic visits). Scores range from 0.01 to 1.0 with higher scores suggesting increased levels of care intensity. Psychometric testing of the KICS was performed in one 54-bed, pediatric skilled nursing facility. A review panel of three experts examined content and construct validity of the KICS. Interrater reliability was tested by comparing intensity scores between two expert pediatric nurses with comparable education and LTC clinical experience for seven pediatric residents with CMC.

Resident intensity scores on the KICS were correlated with scores on the CMI, an index that is used to represent differences in care needs for adult residents of nursing homes. CMI indices are derived from scores on the Resource Utilization Groups (RUGS), a product of the resident assessment process using the Minimal Data Set (MDS). CMI scores determine Medicare reimbursement rates.

Population Studied:
Principal Findings: Mean KICS and CMI composite scores were 0.99 and 1.35, respectively. There was a high correlation between raters for composite scores (Spearman’s rho =0.93, p < 0.003) and subcategories of skilled (rho=0.96, p=<0.001) and restorative nursing care (rho=0.93, p=0.002). No statistically significant correlation was observed between raters for three of the five KICS’ subcategories including basic nursing care, medication administration, and specialty care clinic visits outside the facility (p >0.05), and content mapping demonstrated inconsistencies for these conceptual and operational definitions. No statistically significant association was observed between resident CMI and intensity composite scores (p > 0.05).

Conclusions: The KICS tool met criteria for a minimal standard of reliability; however validity has not yet been established. The lack of association between the KICS and the CMI speaks to the diversity among children with CMC who are likely to differ in service needs from adults.

Implications for Policy, Delivery, or Practice: Appropriate provision of healthcare resources is dependent on the development of tools that could most accurately predict service needs for children with CMC. In the next phase of the project, we will use these findings to revise and re-evaluate the KICS.

Poster Session and Number: B, #537

The Effects of Foreign Educated Nurses on Nurse and Patient Outcomes: What About the Work Environment?
Donna Neff, University of Florida; Dr. Jeffrey Harman, University of Florida Department of Health Services Research, Administration and Management

Presenter: Donna Neff, Ph.D., R.N., FNAP, Associate Professor, College of Nursing, University of Florida, dneff@ufl.edu

Research Objective: To determine whether hospital employment of foreign educated nurses is associated with nurse outcomes, quality of care and patient safety outcomes (PSIs) (medication errors, falls with injury, healthcare-associated nosocomial infections and pressure ulcers).

Study Design: A cross-sectional, observational study designed to measure the direct and interacting effects of hospital nurse staffing and the percentage of foreign-educated nurses on nurse burnout, job satisfaction, work environment and PSIs.

Population Studied: Primary data from a 2008 survey 8,853 nurses employed by 176 hospitals
in Florida. Of the nurse in this study, 1072 nurses were educated outside the US.

**Principal Findings:** The hospital proportion of FENs had no main effect on any of the outcomes and the interaction of proportion of FENs and nurse work environment was also not significant. However, work environment alone significantly predicted all outcomes in all of the models.

**Conclusions:** We provide the first empirical evidence demonstrating that hospital employment of non-US educated nurses in US hospitals is not associated with poor nurse outcomes, poor perceived quality of care or adverse patient outcomes. In fact, nurse work environment was the sole predictor of these outcomes.

**Implications for Policy, Delivery, or Practice:** Consistently, research has found that nurse perceptions of their work environment are key predictors of both nurse and patient safety. In this study, we found that regardless of country of origin, a professional nurse work environment that has adequate staffing, respectful nurse and physician relationships and administrative support of patient-centered care was found to have improved outcomes. Findings add fuel to the ongoing discussions at the national and state policy levels!

**Funding Source(s):** NIH, National Council of State Boards of Nursing

**Poster Session and Number:** B, #538

**Do Hospitalist Programs Improve Patient Care?**

Dwight Neilson, Premier, Inc.; Michael Duan, Premier, Inc.; John Martin, Premier, Inc.; Howard Bankowitz, Premier, Inc.; Neilson Dwight

**Presenter:** Dwight Neilson, M.S., Senior Research Analyst, Premier Insights, Premier, Inc., dwight_neilson@premierinc.com

**Research Objective:** The hospitalist specialty is a fast growing medical specialty. Presently, over two-thirds of US hospitals have a hospitalist program. On the basis of our previous study, we set out to test further whether hospitalist programs were linked to improvements in patient care using regression modeling techniques.

**Study Design:** The study assumed internal medicine (IM) and family practice (FP) as the comparable specialties of hospitalist. Three risk-adjusted outcomes, including mortality, length of stay and cost, were examined across the two cohorts among five diseases that were regularly attended by IM or FPs and served as clinical focus groups (CFGs) for this study. Analyses were conducted at both the hospital level and patient level.

For the hospital-level analysis, hospitals were divided into three groups based on their use of hospitalists. Linear regression analyses were used with the risk-adjusted outcomes being the dependent variables and the hospital characteristics, including the hospitalist utilization, being the predictor variables. For the patient-level analysis, hospitalist and IM/FP cohorts were created from propensity scores based on patient and hospital characteristics. The risk-adjusted outcomes were again used as the dependent variables in regression analyses in which the sole predictor variable was that of hospitalist/IM/FP practitioner.

**Population Studied:** The study was based on 8.5 million inpatient discharges from 382 acute-care hospitals over a two-year period (2008q4-2010q3). After one-to-one propensity score matching, about 372,000 cases were selected from five CFGs (acute cerebrovascular disease, acute myocardial infarction, congestive heart failure, pneumonia, and sepsis). The attending physicians were either hospitalists or IM/FPs.

**Principal Findings:** At the hospital level, the mortality rates of patients cared for by hospitalists were significantly lower at the p<0.05 level across four CFGs (AMI $\beta=-0.01718$, CHF $\beta=-0.01115$, pneumonia $\beta=-0.00425$, sepsis $\beta=-0.02124$) and not significantly higher in the remaining group (ACD $\beta=0.00117$). The length of stay was significantly lower (p<0.01) across all five CFGs. However, the costs of patients cared for by hospitalists were not significantly different than those cared for by IM/FPs, with there being slightly lower costs in four CFGs and slightly higher costs in one.

At the patient level, hospitalist-treated patients had significantly lower mortality rates (p<0.01) across all five CFGs, than those treated by IM/FPs. Coefficients ranged from -0.02727 to -0.006160 depending on the CFG. There were also significantly lower length of stay and costs (p<0.01) across all five groups, with length of stay coefficients ranging from -0.71813 to -0.52479 and cost ranging from -1,310.22 to 716.97.

**Conclusions:** Hospitalists performed better than their IM/FP colleagues in all three
Implications for Policy, Delivery, or Practice: With a third of US hospitals without hospitalist programs, policies encouraging growth in the number of physicians focusing in this specialty may substantially improve inpatient care. Alternatively, identifying practices and procedures used by hospitalists to achieve such performance and transferring those to other specialties should also be encouraged.

Measuring Behavioral Health in the Context of Work: Psychometric Evaluation of a Behavioral Health Function Measurement Tool for Work Disability Determination

Elizabeth Marfeo, Boston Univeristy Health & Disability Research Institute; Pengsheng Ni, Boston University School of Public Health; Elizabeth Marfeo, Boston University School of Public Health; Kara Bogusz, Boston Universityer Health & Disability Research Institute; Mark Meterko, Boston Univeristy Health & Disability Research Institute; Christine M. McDonough, Boston Universityer Health & Disability Research Institute; Leighton Chan, National Institutes of Health, Mark O. Hatfield Clinical Research Center Rehabilitation Medicine Department; Elizabeth K. Rasch, National Institutes of Health, Mark O. Hatfield Clinical Research Center Rehabilitation Medicine Department; Alan M. Jette, Boston Univeristy Health & Disability Research Institute

Presenter: Pengsheng Ni, MD, MPH, Research Assistant Professor, Health Policy & Management, Boston University School of Public Health, psni@bu.edu

Research Objective: To develop and conduct psychometric evaluation of a new assessment tool measuring behavioral health function relevant to work—the Social Security Administration Behavioral Health Function (SSA-BH) Instrument.

Study Design: Data were collected from a cross-sectional survey consisting of 165 items administered to two samples of US adults—(1) a sample of claimants applying for SSA disability benefits due to mental health conditions, and (2) a normative sample of US adults. Building upon results from previous factor analytic work, item response theory (IRT) analysis was used to calibrate the SSA-BH and computer adaptive test (CAT) simulations were conducted to evaluate its psychometric properties including reliability, accuracy, and breadth of content coverage. Functional profiles were generated for SSA claimants compared to age and gender matched norms for the four scales: Mood and Emotions, Self Efficacy, Social Interactions, and Behavioral Control.

Population Studied: A sample of adults applying for Social Security disability benefits (N=1015); and a sample of US adults to develop normative scores (N=1000).

Principal Findings: The SSA claimant sample had a mean age of 44, SD 11 years; was approximately 56 percent female and 61 percent white. The normative sample had an average age of 49, SD 15 years with 52 percent males and 77 percent white. IRT analyses supported the development of a 79 item, four-scale SSA-BH instrument: Mood and Emotions (35 items), Social Interactions (6 items), Self Efficacy(23 items), Social Interactions (6 items), and Behavioral Control (15 items). All SSA-BH scales demonstrated robust psychometric properties including high correlations of the simulated 5- or 10- item CATs with the full item bank (r greater than 0.91), very little loss of reliability and precision of the 5- and 10- item CATs compared to the full item bank, and minimal ceiling and floor effects. Resulting SSA-BH score profiles of SSA claimants versus normative scores differed in the expected direction for all four scales of behavioral health function.

Conclusions: The SSA-BH represents a significant psychometric advancement in current measurement of work related behavioral health function. Initial testing and evaluation of the SSA-BH instrument demonstrated high degrees of accuracy, reliability, and broad content coverage along all four scales. These findings support the potential utility of integrating a CAT-based measurement approach to collect standardized, comprehensive functional information about claimants for purposes such as SSA disability evaluation.

Implications for Policy, Delivery, or Practice: The US Social Security Administration’s (SSA) disability programs provide financial support to over 18 million disabled individuals and their families. Mental health impairments represent a significant proportion of the disabling conditions for which individuals receive work disability...
benefits (SSDI). The nature of mental health related disability is complex and multifaceted, making systematic, accurate measurement challenging and resource intensive. Advanced methodologies in health assessment based on IRT and CAT were used in the development to the SSA-BH. These modern assessment methodologies allow for significant gains in efficiency and accuracy in terms of measuring complex health phenomena such as behavioral health related work disability. The SSA-BH instrument’s notable psychometric properties provide initial evidence to support its incorporation within the context of SSA’s disability evaluation processes.

**Development and Psychometric Evaluation of a Computer Adaptive Physical Function Instrument for Social Security Administration Disability Determination**

Pengsheng Ni, Boston University Health & Disability Research Institute; Pengsheng Ni, Boston University School of Public Health; Elizabeth E. Marleo, Boston University Health & Disability Research Institute; Christine M. McDonough, Boston University Health & Disability Research Institute; Alan M. Jette, Boston University Health & Disability Research Institute; Kara Bogusz, Boston University Health & Disability Research Institute; Elizabeth K. Rasch, National Institutes of Health, Mark O. Hatfield Clinical Research Center Rehabilitation Medicine Department; Diane E. Brandt, National Institutes of Health, Mark O. Hatfield Clinical Research Center Rehabilitation Medicine Department; Leighton Chan, National Institutes of Health, Mark O. Hatfield Clinical Research Center Rehabilitation Medicine Department

**Presenter:** Pengsheng Ni, MD, MPH, Research Assistant Professor, Department of Health Policy & Management, Health & Disability Research Institute, Boston University School of Public Health, psni@bu.edu

**Research Objective:** To develop and test a new instrument measuring physical function relevant to work—the Social Security Administration Physical Function (SSA-PF) Instrument.

**Study Design:** Data collected from a 139-item survey administered to two samples of US adults—(1) claimants applying for SSA disability benefits because of limitation(s) in work-related physical function, and (2) a normative sample of US adults were used to develop and test the SSA-PF. Prior factor analytic work supported further development of the SSA-PF using item response theory (IRT) data analyses methods for instrument calibration and computer adaptive test (CAT) simulations to evaluate the psychometric properties of the SSA-PF instrument. Distinct functional profiles were generated for SSA claimants to compare age and gender matched norms along five scales: Changing & Maintaining Body Position, Whole Body Mobility, Upper Body Function, Upper Extremity Fine Motor, and Wheelchair Mobility.

**Population Studied:** A sample of SSA disability claimants (N=1017), and a normative sample of US adults (N=999).

**Principal Findings:** The mean age of the claimant sample was 49, SD 10 years; the normative sample 49, SD 16 years. The SSA claimant sample was approximately 53 percent male and 59 percent white; the normative sample was approximately 52 percent male and 78 percent white. IRT analyses supported the construction of the SSA-PF a 99 item, five scale instrument: Changing & Maintaining Body Position (23 items), Whole Body Mobility (16 items), Upper Body Function (23 items), Upper Extremity Fine Motor (29 items), and Wheelchair Mobility (8 items). The SSA-PF scales demonstrated strong psychometric properties including high correlations (r greater than 0.95) between the simulated 5- and 10-item CATs with scores based on the full item bank; the shorter versions demonstrated little loss of reliability or precision. Score profiles generated for SSA claimants and compared to age and gender matched norms differed in the expected direction along all five dimensions of physical function.

**Conclusions:** The SSA-PF instrument contributes a new tool for measuring the work related physical function for adults applying to the SSA disability programs. Overall, our initial psychometric evaluation indicated excellent accuracy, reliability, and content coverage along all five scales. This work represents significant psychometric advancements in the measurement of physical function relevant to the context of work.

**Implications for Policy, Delivery, or Practice:** The US Social Security Administration’s (SSA) disability programs are large federal programs, which provide financial resources to over 18 million disabled individuals and their families. Physical impairments represent the largest
group of work disabling conditions among current SSDI claimants. Collection of functional assessment data using efficient and accurate methodologies is essential for streamlining current disability determination processes. Measuring the nature of disability with a focus on various aspects of physical function requires a multifaceted approach. Advanced methodologies in health assessment based on IRT analysis and CAT administration allow for an appropriately multifaceted approach that more efficiently and accurately measures work-related physical function. The SSA-PF instrument's strong psychometric properties may provide initial support for utilizing this tool within the context of SSA's disability evaluation processes.

**Psychological Safety Assessment within Veterans Health Administration Hospitals**

Ryan Derickson, Veterans Health Administration; Katerine Osatuke, Veterans Health Administration; Jonathan Fishman, Veterans Health Administration; Janis Beckstrand, Veterans Health Administration

**Research Objective:** In psychologically safe workplaces, employees feel comfortable taking interpersonal risks without fear of retaliation (Edmondson, 2002). Systematically supporting this climate optimizes clinical and operational outcomes (Edmondson, 1996; 1999). Race and supervisory level can shape healthcare employee perceptions of workplace climate (DesRoches et al., 2010; Nembhard & Edmondson, 2006). Using mixed-method approach to Veterans Health Administration (VHA) data, we investigated relationships between psychological safety, race, and supervisory level.

**Study Design:** Psychological safety survey ratings were evaluated across race and supervisory levels and compared to employees' interviews data. Quantitative. The VHA All Employee Survey (AES) is an annual confidential census of workplace climate. Two AES questions address psychological safety: (PS1) "Members of my workgroup are able to bring up problems and tough issues"; PS2 "It is safe to take a risk in

this workgroup". To determine if psychological safety relates to race and supervisory level, we conducted two ANOVAs using PS1-2 mean scores as DVs, with race (White, minority, and multiracial) and supervisory level (1-non-supervisory; 6-senior executive) as IVs. Qualitative. Employee interviews confidentially conducted by organizational consultants at VHA hospitals asked why employees would/would not report a medical/ethical violation and what might prevent others from reporting. Transcribed responses were analyzed by three trained coders using NVivo software. Themes derived using grounded theory (Glaser & Strauss, 1967) from a larger subset were applied to 374 interviews.

Mixed Methods. We analyzed interview responses from a hospital below the 3.57 national mean of PS1 (hospital A; M=3.47, t(1,301)=2.98, p<.005) and above the national mean (hospital B; M=3.66, t(1,848)=3.66, p<.005) and examined how many employees at each would/ would not report an error/violation (hospital A: n=93, hospital B: n=113).

**Population Studied:** VHA employees

**Principal Findings:** Quantitative. Significant main effect for race F(1,189,915)=361.07, p<.001. The White employees' mean (3.38, n=128,590) was higher than minorities (3.29, n=54,438) and multiracial employees (3.06, n=6,890). Race only accounted for .4% psychological safety variance (\(\eta^2=.004\)). Significant main effect for supervisory level (F(5,199,258)=1223.46, p<.001, \(\eta^2=.03\)). In Tukey follow-up tests, psychological safety increased with supervisory levels, except executives to senior executives.

Qualitative. 76% of respondents said they would always report an error; professional ethics were their main motivation. 11% said the type/severity of error would influence their decision. 12% said they would never report, citing fear of retaliation as their main deterrent.

Mixed Methods. 71% of hospital A (low PS1) respondents stated they would report an error; 13% would not. Conversely, at hospital B (high PS1), 91% said they would report an error; no one said they would not report.

**Conclusions:** Race explained little variance in psychological safety, suggesting VA employees are not experiencing racially-dependent influences on psychological safety. The supervisory level results corroborated previous findings; psychological safety increases with power (Nembhard & Edmondson, 2006). Interview analyses suggested that some
employees openly reveal they would not report an error; i.e. social desirability did not induce respondents to claim otherwise.

Implications for Policy, Delivery, or Practice: Our mixed-method results linked psychological safety climate and intended behaviors of healthcare employees. Creating psychologically safe workplaces may facilitate error reporting, thereby lowering the operational and clinical costs of errors and improving patient outcomes.

Measuring Burnout and Its Effects within Veterans Health Administration
Emily Crowe, Veterans Health Administration; Katerine Osatuke, Veterans Health Administration; Robert Teclaw, Veterans Health Administration; Jan Beckstrand, Veterans Health Administration; Katerine Osatuke, Veterans Health Administration

Presenter: Katerine Osatuke, Ph.D., Health Scientist, Veterans Health Administration, katherine.osatuke@va.gov

Research Objective: Burnout at workplace involves emotional exhaustion, depersonalization, and reduced personal accomplishment (Schaufeli, 1999; Maslach & Jackson, 1981). Healthcare professionals are especially susceptible to burnout given their highly demanding tasks (e.g. taking care of sick patients). Since employees are the main vehicle of care delivery, beyond personal costs to employees, burnout impacts patient care and satisfaction (Garman, Corrigan, & Morris, 2002), thus ultimately affecting the quality of services. Veterans Health Administration (VHA) is committed to improving its employees’ work lives and providing excellent patient care. VHA measured burnout in its confidential census survey to gauge its incidence and correlates. This study presents results of this pilot assessment.

Study Design: We applied exploratory analyses to data from the 2012 All Employee Survey (AES), VHA census of workplace perceptions and job satisfaction (N=273,556; 63.4% participation). The piloted burnout measure asked respondents to select their ratings from 1=I enjoy my work, I have no symptoms of burnout to 5=I feel completely burned out and often wonder if I can go on. I am at the point where I may need some changes or may need to seek some sort of help.

We used frequency counts to determine the incidence of burnout and logistic regression to examine which demographic characteristics, job satisfaction aspects, and specific workplace perceptions were associated with endorsing either of the top two burnout categories. Because many survey items are correlated, all items were entered into the model to determine potential associations in the presence of the other IV’s.

Population Studied: VHA employees
Principal Findings: 30% of VHA respondents reported burnout, with Inpatient Medical/Surgical and Intensive Care/Critical Care reporting the highest rates. Physicians and low grade employees reported significantly lower burnout rates than nurses, other clinical, and administrative employees. The five (of 19) services with the highest burnout rates were Inpatient Medical/Surgical, Intensive Care/Critical Care, Laboratory and Pathology, Primary Care, and Prosthetics/Sensory Aids. Burnout was positively associated with being younger, female, not Black or Asian, of longer tenure, and non-supervisory status. 27 of 43 survey items were significantly associated with burnout, but the effect sizes measured by odds ratios were small for most. Burnout was strongly associated with satisfaction with the amount of work, overall satisfaction, working conditions, working fast, and feeling that the VA cares about their general job satisfaction, all in the expected direction.

Conclusions: Burnout is not evenly distributed among hospital staff. Paradoxically, younger employees are more likely to be burned out, but employees with less tenure in the organization are less likely to be so. Although burnout is statistically significantly associated with many specific workplace perceptions the AES measured, only a few items showed strong relationships: amount of work, working conditions, speed of work, overall satisfaction, and employee perceptions of whether VA cares about their satisfaction.

Implications for Policy, Delivery, or Practice: Our findings point to specific aspects of healthcare workplace that need to be monitored and proactively addressed to prevent burnout. We also identify demographic and occupational groups particularly vulnerable to burnout. These results directly inform workforce support initiatives in healthcare organizations.

The Role of Coping in Depression Treatment Utilization in VA Primary Care Patients

Princess Osei-Bonsu, PhD, MSPH, Center for Health Quality, Outcomes, and Economic Research; Barabara G. Bokhour, PhD, Center for Health Quality, Outcomes, and Economic Research; Stephanie Rodrigues, PhD, Center for Health Quality, Outcomes, and Economic Research; Nora Mueller, MAA, Center for Health Quality, Outcomes, and Economic Research; Mark Glickman, PhD, Center for Health Quality, Outcomes, and Economic Research; Shibei Zhao, MPH, Center for Health Quality, Outcomes, and Economic Research; Susan V. Eisen, PhD, Center for Health Quality, Outcomes, and Economic Research; A. Rani Elwy, PhD, Center for Health Quality, Outcomes, and Economic Research;

Population Studied: Veterans (N=271) receiving primary care in three VA medical centers were mailed questionnaires if they screened positive for depression on the mandated annual VA PHQ-9 (>10) or PHQ-2 (>3) depression screen, had not received a diagnosis of depression in the past 12 months, and were not prescribed any anti-depressants in the 12 months prior to their screening date. A subsample (n=23) of these veterans participated in a qualitative interview. 

Principal Findings: Three different binary outcomes of receipt of mental health treatment three months after a positive depression screen were constructed based on the degree of treatment received (“treatment” defined as VA guideline-concordant depression treatment, depression treatment not concordant with VA guidelines, or other mental health treatment). Logistic regression models showed that participants who reported using instrumental support and active coping were more likely to receive depression and other mental health treatment within three months of their positive depression screen. Those who used emotional support and self-distraction strategies were less likely to receive any treatment in the same time frame. Grounded thematic analysis of the interviews revealed that Veterans used these four coping strategies as well as others such as positive reframing, venting, planning, and substance use. In addition, it appeared that similar strategies may have a different impact on treatment engagement. For example, one Veteran who engaged in depression treatment exercises regularly, and believes that exercise helps him because it releases endorphins. Another Veteran indicated that he uses yoga for his comorbid PTSD and did not engage in depression treatment post-screening.

Conclusions: From a quantitative perspective, the use of coping strategies, namely active coping, instrumental support, emotional support, and self-distraction can impact Veterans’ treatment engagement for depression. Qualitatively, the results indicate that Veterans use a variety of coping strategies which, depending on their individual contexts, may lead to different levels of treatment engagement for depression.

Implications for Policy, Delivery, or Practice: Patients with depression can delay seeking treatment for as long as 8 years. Thus, it is important for providers to understand and discuss with their depressed patients the types of coping strategies they use and how they are impacting their treatment engagement.

The Effect of Utilizing Community Health Workers to Address Patients’ Social Needs on Primary Care Practice
Thearis Osuji, ICF International; Marnie J. House, Ed.D., MPH, ICF International; Julia Fine, MPH, ICF International

Research Objective: Despite many public health efforts, hypertension (also known as high blood pressure) rates in the U.S. have remained steady over the last 10 years with no sign of decline. In a Robert Wood Johnson Foundation (RWJF) survey of 1,000 U.S. physicians conducted in 2011, 80% of physicians agreed that “patients’ social needs are as important to address as their medical conditions,” while 85% of physicians felt there was a direct correlation between not addressing social needs and worsening health. This highlights a growing problem known as “health care’s blind side,” where there are not enough resources and time for physicians to help patients with their social needs, including unemployment, housing assistance, eating nutritiously, or exercising regularly (RWJF, 2011). Community health worker (CHW) programs can help close this gap between social and medical needs, thereby improving quality of life and ultimately the management of chronic illnesses such as hypertension. For the Centers for Disease Control and Prevention, ICF International is conducting an evaluation of the St. Johnsbury, Vermont, Community Health Team (CHT) model which was developed under the auspices of the Vermont Blueprint for Health. In the St. Johnsbury CHT model, CHWs link patients to economic, social, mental health and community supports via state agencies and community-based organizations to assist them in improving their disease management and quality of life. The purposes of this study are to: (1) detail implementation processes to inform practice, and (2) determine the impact of the CHT model on patient outcomes related to quality of life and hypertension.

Study Design: This multi-method study involves both quantitative and qualitative methods. In this presentation, the authors will focus on findings from the qualitative methods which include systematic document reviews and in-depth interviews with CHT members and providers.

Population Studied: An estimated 17,325 patients are attributed to medical homes in St. Johnsbury, which is the largest town and commercial center in a predominantly rural service area. In 2009, approximately 18.9% of the population lived below the poverty line compared to 11.4% statewide.

Principal Findings: The implementation of the St. Johnsbury CHT model has affected the quality of care among primary care providers in the area. It has helped reduce burden by providing referral resources for providers to assist patients with complex social and health issues instead of taking time to address these issues in the limited timeframe of clinical encounters. Providers also expressed that since the implementation of this model, they are more willing to talk with patients about their social needs and the impact on their health.

Conclusions: Findings from this study suggest that CHWs can be engaged in multidisciplinary health care teams to address patients’ social needs, promote well-being in communities and reduce burden on primary care providers.

Implications for Policy, Delivery, or Practice: Implementation of a care model that utilizes CHWs to address social needs may help improve quality of care and provide patients with the resources and assistance needed to live healthy lives.

Funding Source(s): CDC

Impact of Severity Measures on Patient Satisfaction Integration Process
Koichiro Otani, Indiana University - Purdue University (IPFW)

Research Objective: The purpose of this study was to investigate how the severity of illness level influences patients’ attribute reaction integration process to arrive at their overall satisfaction. Thus, this study aims at finding how seriously ill patients differ from less seriously ill patients.

Study Design: A multiple linear regression analysis with a scatter term, a severity measure, and interaction effects of the severity measure was conducted while controlling for age, gender, and race.

Poster Session and Number: B, #545
**Population Studied:** Data were collected from 5 large hospitals in the St. Louis areas by using a patient satisfaction questionnaire.

**Principal Findings:** The severity of illness variable itself was not statistically significant in either the overall quality of care or willingness to recommend to others model, but revealed the interaction effects with physician care, staff care, food, and scatter term variables in the willingness to recommend to others model.

**Conclusions:** With more seriously ill patients, physician care becomes more important, and staff care becomes less important, and seriously ill patients are proportionately more likely to combine their attribute reactions only in the willingness to recommend to others model.

**Implications for Policy, Delivery, or Practice:** All six attributes (admission process, nursing care, physician care, staff care, food, and room) are not equally influential. Nursing care and staff care show consistent influence in both models. These findings show that if health care managers need to improve their patient satisfaction, they should improve nursing care and staff care first. They would see the most improvement.

**Review of Existing Overuse Measures for USPSTF D Recommendations and Choosing Wisely List of Questionable Healthcare Services: High Yield Prospects for Overuse Measure Development**

Divya Pamnani, National Committee for Quality Assurance; Bob Rehm, National Committee for Quality Assurance; Najilla Nassery, Johns Hopkins University School of Medicine; Mary B. Barton, National Committee for Quality Assurance

**Presenter:** Divya Pamnani, M.H.S.A., Healthcare Analyst, Performance Measurement, National Committee for Quality Assurance, pamnani@ncqa.org

**Research Objective:** The Agency for Healthcare Research and Quality defines overuse as the provision of care such that the potential for harm exceeds the potential for benefit. Overuse is responsible for approximately 30 percent of US healthcare spending. In an effort to concurrently improve quality and reduce costs, the federal government has made reduction in overuse a priority in its National Quality Strategy. Despite the urgent need to improve healthcare affordability, performance measures for overuse, unlike measures for underuse, have been underrepresented in the quality measurement landscape. The purposes of this project are to quantify the number of existing overuse performance measures and identify opportunities for measure development.

**Study Design:** The U.S. Preventive Services Task Force (USPSTF) D recommendations and Choosing Wisely campaign provided a framework and good starting point for research into possible overuse areas. We reviewed USPSTF D recommendations (i.e., services that have no net benefit or services where the harms outweigh the benefits for a general population) and the 2012 Choosing Wisely list of questionable healthcare services (presented by the American Board of Internal Medicine as a collaboration with nine medical specialty organizations). We subsequently searched the National Quality Forum’s (NQF) inventory of endorsed performance measures, as well as measures currently known to be in development, to identify those that mapped to overused services identified by USPSTF D or Choosing Wisely. To meet the second objective, we shortlisted opportunities for new measure development based on public health importance, strength of evidence and feasibility of implementation.

**Population Studied:**

**PrincipaL Findings:** Thirty-seven USPSTF D recommendations and 45 Choosing Wisely services were identified. These included high-cost items and low-unit cost, high frequency items. Those identified by USPSTF D were applicable primarily to asymptomatic populations while those identified by Choosing Wisely were more likely to be condition specific, relevant to populations under the care of specialists. The 82 total cited overused services mapped to 37 overuse measures. Of these 37 measures identified, 25 were NQF endorsed and 12 were measures in development. The measures represented different sources of accountability including provider, practice, health plan, acute care facility and emergency department. Opportunities for measure development were identified from both sources – USPSTF D and Choosing Wisely. There was variation in terms of public health importance, strength of evidence, and feasibility of implementation among the identified overused services. Ambiguity around exclusions, or caveats such
ICH Dialysis Center). CMS is currently using the items (Kidney Doctor, Dialysis Center Staff and Patient Information) and 3 composite scores (Nephrologists’ Communication, Quality of Care, and Patient Information) to assess patient experiences of care but there is no published information on the psychometric properties of the instrument.

**Conclusions:** Our research reveals that while there are some measures available, new high impact overuse measures are needed. Performance measurement targeting this domain is ripe for development, having the potential to be an important lever for changing clinician behavior through feedback, public reporting, clinical decision support and financial incentives.

**Implications for Policy, Delivery, or Practice:**
The landscape for overuse measures is changing. Additional specialty societies will be joining the Choosing Wisely campaign, and USPSTF continues to refine its recommendations. Moreover, the spread of electronic health records as clinically rich data sources lends itself as fertile ground for implementing existing and developing new measures beyond administrative claims.

**Evaluation of the Psychometric Properties of the In-Center Hemodialysis Survey - Consumer Assessment of Healthcare Providers and Systems in Chronic Kidney Disease Patients on Dialysis**

Robert Wood, Adelphi Real World; Carly Paoli, Amgen, Inc.; Ron D. Hays, University of California; Gavin Taylor-Stokes, Adelphi Real World; James Piercy, Adelphi Real World; Matthew Gitlin, Amgen, Inc.

**Presenter:** Carly Paoli, PharmD, MPH, Health Economics Manager, Global Health Economics, Amgen, Inc., cpaoli@amgen.com

**Research Objective:** In 2011, the Centers for Medicare and Medicaid Services (CMS) implemented an End Stage Renal Disease (ESRD) Prospective Payment System (PPS) for Medicare reimbursement of outpatient dialysis-related services along with a Quality Incentive Program (QIP) to monitor quality of care of dialysis facilities. Some QIP measures utilize patient-reported outcomes (PRO) as process metrics. The ICH-CAHPS is a 58-item questionnaire, which yields 3 composite scores (Nephrologists’ Communication, Quality of Care, and Patient Information) and 3 global rating items (Kidney Doctor, Dialysis Center Staff and Dialysis Center). CMS is currently using the ICH-CAHPS to assess patient experiences of care but there is no published information on the psychometric properties of the instrument.

**Study Design:** Data are from the 2012 Adelphi CKD Disease Specific Program (DSP), a cross-sectional survey of US nephrologists and their patients, in addition to a patient questionnaire to obtain PRO outcomes (including the ICH-CAHPS). Assessment of the psychometric properties of the three composite scores included an evaluation of item-scale correlations and internal consistency reliability (Cronbach’s alpha).

**Population Studied:** 404 patients were eligible for this analysis from 76 centers. 56% of patients were male. The mean age of patients was 57 years with 33% over the age of 65 years, and mean time on dialysis was over 3 years (range 13-1352 weeks). The sample is very similar to the United States Renal Data System (USRDS) 2011 dialysis population in terms of age and gender.

**Principal Findings:** For Nephrologists’ Communication, 5 of 6 items had item-scale correlations (corrected for item overlap) greater than or equal 0.4 and all items had stronger correlation with Nephrologists’ Communication than the other 2 composites; internal consistency reliability was supported by a coefficient alpha of 0.81. Fourteen of the 17 Quality of Care items correlated greater than or equal 0.4 with the composite with most items correlating more highly with Quality of Care than the other two composites; coefficient alpha was 0.90. For Patient Information, none of the items had an item-scale correlation coefficient greater than or equal 0.4 with the composite and coefficient alpha was only 0.55.

**Conclusions:** The analysis demonstrates good item-convergence and item-discrimination as well as satisfactory internal consistency reliability for the Nephrologists’ Communication and Quality of Care composites.

**Implications for Policy, Delivery, or Practice:** These results suggest that additional psychometric evaluation is needed prior to using ICH-CAHPS as a CMS clinical performance measure.

**Funding Source(s):** Other, Amgen, Inc.

Associations between the Consumer Assessment of Healthcare Providers and Systems (CAHPS®) In-Center Hemodialysis Survey and Patient and Dialysis Facility Characteristics among Chronic Hemodialysis (HD) Patients in the United States (US)
Carly Paoli, Amgen, Inc.

**Presenter:** Carly Paoli, Pharm.D., M.P.H., Health Economics Manager, Global Health Economics, Amgen, Inc., cpaoli@amgen.com

**Research Objective:** To estimate associations of CAHPS-ICH composites and global rating items with selected patient and facility characteristics.

**Study Design:** This study examines whether selected patient characteristics and structural variables within a dialysis facility are related to dialysis patients’ perception of health care received. Data are from the Adelphi Real World Chronic Kidney Disease (CKD) disease specific program, a cross-sectional survey of physicians and their patients in the first quarter of 2012. The CAHPS-ICH survey assesses the experiences of HD patients who receive care from dialysis facilities. It yields 3 multi-item composite scores (Nephrologists' Communication, Quality of Care, and Patient Information) scored on a scale from 1-4 (except Patient Information, scored 0-1) and 3 global rating items (Kidney Doctors, Dialysis Center Staff, and Dialysis Center) scored on a scale from 1-3. CAHPS-ICH scores were analyzed across patient (age; gender; BMI; vascular access type; ethnicity; employment status; time since diagnosis; dialysis vintage; ever receiving anemia management education; hemoglobin level) and facility (patient to technician, nurse and physician ratios; number of shifts at facility; number of chairs/stations at the facility, patient wait time; patient’s time between appointments with a physician) characteristics (all variables were categorical, not all shown in results here) using one-way ANOVAs.

**Population Studied:** Nephrologists treating a minimum of 20 HD patients a month and actively involved in their treatment decisions completed patient record forms on 10 randomly selected, prevalent HD (on dialysis= 3 months) patients. Those 10 patients were given a survey with additional questions (including the CAHPS-ICH).

**Principal Findings:** There were 76 facilities treating 404 eligible patients in the study. Mean patient age was 57 years, mean dialysis vintage was 3 years, and 44% were female. Mean # of patients per technician, nurse, and physician was 4, 9, and 28, respectively. There were 55% of patients who reported having received any anemia education. While the trend was not entirely consistent, patient:nurse ratio (<5/nurse, 5 to <8, 8 to <12 and 12+) differentiated CAHPS-ICH scores in Quality of Care (3.56, 3.52, 3.39 and 3.41 respectively, p<0.05), Patient Information (0.91, 0.84, 0.76 and 0.84 respectively, p<0.01), global rating of the Dialysis Center (2.67; 2.62, 2.40, and 2.52 respectively, p<0.05), and global rating of the Dialysis Center Staff (2.66, 2.58, 2.37, and 2.51 respectively, p<0.05). Patients receiving anemia education (yes vs. no) reported more positive experiences with Patient Information (0.89 vs. 0.78, p<0.01) and rated the Dialysis Center Staff more positively (2.60 vs. 2.46, p<0.05).

**Conclusions:** Some CAHPS-ICH composite scores and global rating items are sensitive to patient and facility characteristics in a sample of facilities treating CKD patients on HD in the US. **Implications for Policy, Delivery, or Practice:** The Center for Medicaid and Medicare Services (CMS) is using the CAHPS-ICH Survey as a process reporting measure for their End-Stage Renal Disease (ESRD) Quality Incentive Program (QIP). The results of this study demonstrate that CAHPS-ICH can detect some differences across some patient and dialysis facility variables.

Unit-level Nurse Turnover Effects on Pressure Ulcer Outcomes: A Longitudinal Study
Shin Hye Park, University of Kansas Medical Center; Diane K. Boyle, University of Kansas Medical Center

**Presenter:** Shin Hye Park, Ph.D., R.N., Post-Doctoral Fellow, Nursing, University of Kansas Medical Center, spark@kumc.edu

**Research Objective:** High rates of nurse turnover on units may gradually increase the remaining staff’s workload and burnout, affect workforce collaboration among the remaining and new staff, and thus may result in poor patient outcomes in the current and subsequent periods. Many researchers address this adverse relationship between nurse turnover and patient care quality. However, previous studies offer little empirical evidence of a relationship between nurse turnover and patient outcomes.
based on data longitudinally collected from hospitals nationwide. Our study purpose was to examine the lagged and concurrent effects of unit-level registered nurse (RN) turnover rates on unit-acquired pressure ulcer rates using longitudinal data.

**Study Design:** We used a longitudinal, observational design. Quarterly unit-level administrative data were obtained from the National Database of Nursing Quality Indicators (NDNQI) for the years 2008 to 2010. We conducted multilevel logistic regression models, controlling for nurse staffing and hospital and unit characteristics (unit type and hospital Magnet status, size, and patient case mix). For regressions, lagged RN turnover effect was included to determine if influences occurred either contemporarily or with time lags. Average quarterly RN turnover rates were calculated at the unit level. We measured the proportion of patients with a unit-acquired pressure ulcer of any stage among patients surveyed on the units each quarter.

**Population Studied:** Our sample included a total of 15,277 quarter-observations (3,151 units from 478 NDNQI member hospitals). Unit types included were critical care, step-down, medical, medical-surgical, surgical, and rehabilitation for adult patients.

**Principal Findings:** We found that nursing units with higher RN turnover rates in a quarter were expected to have higher rates of unit-acquired pressure ulcers in the next quarter (odds ratio, OR=1.006, p=.002). For every 10 percentage-point increase in the RN turnover in a quarter, the odds of a patient having a unit-acquired pressure ulcer increased by 6 percent in the next quarter. No significant association was found between concurrent RN turnover rates and pressure ulcers. Higher RN staffing was associated with lower rates of unit-acquired pressure ulcers (OR=0.973, p=.019). Higher rates of RN turnover in a quarter were associated with lower RN staffing levels in the next quarter.

**Conclusions:** Our findings showed that nursing units with higher RN turnover in a quarter were expected to have higher rates of unit-acquired pressure ulcers in the next quarter; however, there was no concurrent relationship. The negative effect of higher unit-level RN turnover on unit-acquired pressure ulcers was delayed until the next quarter rather than immediately observed.

**Implications for Policy, Delivery, or Practice:** We suggest that RN turnover is an important factor that affects unit-acquired pressure ulcer outcomes and adequate RN staffing levels needed for high quality care. Given the high rates of RN turnover, hospital and nursing administrators should prepare for the negative effect on patient outcomes.

**Poster Session and Number:** A, #93

**Evaluation of the NDNQI Nurse Turnover Data: A Survey of Hospitals**
Shin Hye Park, University of Kansas Medical Center; Diane K. Boyle, University of Kansas Medical Center

**Presenter:** Shin Hye Park, Ph.D., R.N., Post-Doctoral Fellow, Nursing, University of Kansas Medical Center, spark@kumc.edu

**Research Objective:** Since 2007, the National Database of Nursing Quality Indicators (NDNQI), a program of the American Nurses Association, has collected monthly nurse turnover data from nursing units in member hospitals. As of 2011, about 46 percent of member hospitals had participated in nurse turnover data collection. The NDNQI reports quarterly national comparison data on nurse turnover indicators to help member hospitals improve their nursing work environments and quality of care. Although the NDNQI has periodically evaluated data elements, evidence of the quality of NDNQI nurse turnover data collection has not been established fully. Our study purpose was to evaluate the NDNQI nurse turnover data collection based on the National Quality Forum’s criteria (reliability, validity, usability/feasibility, and importance) and to investigate reasons for hospitals not participating in the turnover data collection.

**Study Design:** We randomly surveyed member hospitals during the period February to April 2012. Hospitals were categorized into two groups: those having submitted turnover data at least once since 2007 (Turnover group, n=794) and those not having participated in turnover data collection ever (No-Turnover group, n=926). A long-form questionnaire (Turnover group) was designed with questions about NDNQI’s turnover data collection and reports; a short-form questionnaire (No-Turnover group) was intended to investigate barriers to the turnover data collection. Both the questionnaires were self-administered through an online survey.
tool by hospital site coordinators working with NDNQI turnover data submission.  

**Population Studied:** One hundred-five surveys were returned from the Turnover group (response rate=31.9 percent) and 73 surveys from the No-Turnover group (response rate=22.3 percent). Our sample hospitals were typically teaching institutions located in metropolitan areas.  

**Principal Findings:** The large majority (92.4 percent) of Turnover group hospitals strongly agreed or agreed that their turnover data collection processes were implemented consistently across units and over quarters. About 91 percent of the Turnover group hospitals reported their hospital’s nurse turnover data submitted to NDNQI were accurate. When asked if nurse turnover data reported by NDNQI were useful for nursing workforce management in their hospital, the majority of hospitals strongly agreed (27.6 percent) or agreed (52.4 percent). More than half the hospitals in the No-Turnover group answered that their hospitals collected hospital-level turnover data rather than unit-level data (54.8 percent), and they also cited difficulties in obtaining specific separation reasons (34.3 percent) and identifying separations by nursing staff categories (24.7 percent).  

**Conclusions:** The survey findings supported the validity, reliability, usefulness/feasibility, and importance of NDNQI nurse turnover data collection. The NDNQI nurse turnover data were useful in identifying units with higher turnover rates than desired or units with an increasing trend in turnover rates. But hospitals reported difficulty identifying specific separation reasons, difficulty collecting nurse turnover data at the nursing unit level, and concerns about the amount of time and resources needed for unit-level turnover data collection.  

**Implications for Policy, Delivery, or Practice:** We suggest that the development of hospital-level nurse turnover indicators may be useful to extend member hospitals’ participation in the NDNQI turnover data collection. We also recommend improving the guidelines for identification of specific separation reasons to enhance quality of NDNQI nurse turnover data.

**Admission and Retention of Individuals with Moderate to Severe Cognitive Impairment: Findings from the 2010 National Survey of Residential Care Facilities**  

Eunice Park-Lee, CDC/NCHS; Manisha Sengupta, CDC/NCHS  

**Presenter:** Eunice Park-Lee, Health Scientist, CDC/NCHS, hta8@cdc.gov  

**Research Objective:** Assisted living and similar residential care communities (RCCs) provide an alternative to nursing homes for individuals with dementia and other cognitive impairment. RCCs are not federally regulated, and state approaches to RCC regulations vary widely. Within the parameters set by the state, RCCs decide whether to admit or retain residents with moderate to severe cognitive impairment (MSCI): these policies may affect individuals’ abilities to age in place. Using data from the 2010 National Survey of Residential Care Facilities, we examined provider characteristics associated with different admission and retention policies for residents with MSCI.  

**Study Design:** Two mutually exclusive RCC types were identified: 1) RCCs that neither admit nor retain residents with MSCI; and 2) RCCs that retain residents with MSCI (regardless of whether they admit such residents). Provider characteristics compared by RCC type include: ownership, size, having dementia-specific units, developing formal negotiated risk agreement/similar document, percent of private units in RCC, direct care staff hours per day per resident, and resident case-mix variables. Because of the complex sampling design, analyses were performed using SAS-callback SUDAAN. Estimates were compared using chi-square and t-tests. All significance tests were two-sided using p<0.05.  

**Population Studied:** We examined a nationally representative sample of 2,302 assisted living and similar residential care communities (RCCs).  

**Principal Findings:** About 65% of RCCs would retain residents with MSCI, while the remainder would neither admit nor retain residents with MSCI. RCCs that retain individuals with MSCI were more likely to be for profit, smaller communities with 4 to 25 beds, and have some or all of their units being dementia-specific and higher personal care aide hours per resident per day than RCCs that neither admit nor retain individuals with MSCI. Higher proportions of residents in RCCs that retain residents with
MSCI were bladder incontinent, and received assistance in toileting and with medications compared to those in RCCs that neither admit nor retain individuals with MSCI. Higher percentages of residents who moved out of RCCs that neither admit nor retain individuals with MSCI went to nursing home or hospital than those who moved out of RCCs that retain residents with CI. No significant differences were observed between RCC type relative to developing formal negotiated risk agreement, percent of private units, RN and LPN/LVN hours per resident per day, and resident case-mix by demographics and receiving services paid by Medicaid.

**Conclusions:** Close to two-thirds of RCCs have polices to retain individuals with MSCI. Compared with RCCs that neither admit nor retain residents with MSCI, these communities were more likely to be smaller, for-profit communities, have dementia-specific units and higher personal care aide hours per resident per day, and serve more functionally impaired individuals.

**Implications for Policy, Delivery, or Practice:** Findings on characteristics associated with RCCs that retain residents with MSCI could be useful to consumer advocates, persons with cognitive impairment and their family members when considering which kinds of RCCs may better meet their care needs and preferences, including a desire to age in place.

**Military Sexual Trauma among Homeless Veterans**
Joanne Pavao, VA Palo Alto Health Care System; Jessica A. Turchik, PhD, VA Palo Alto Health Care System; Jenny K. Hyun, PhD, MPH, VA Palo Alto Health Care System; Julie Karpenko, MSW, VA Palo Alto Health Care System; Meghan Saweikis, MS, VA Palo Alto Health Care System; Susan McCutcheon, EdD, RN, VA Mental Health Services; Vincent Kane, MSS, National Center on Homelessness Among Veterans; Rachel Kimerling, PhD, VA Palo Alto Health Care System

**Presenter:** Joanne Pavao, M.P.H., Health Science Specialist, National Center for PTSD, VA Palo Alto Health Care System, joanne.pavao@va.gov

**Research Objective:** Military sexual trauma, MST, is the Veteran Health Administration’s, VHA, term for sexual assault and/or sexual harassment that occurs during military service. The experience of MST is associated with a variety of mental health conditions. Preliminary research suggests that MST may be associated with homelessness among female Veterans, although to date MST has not been examined in a national study of both female and male homeless Veterans. The objective of the current study is to estimate the prevalence of MST, examine the association between MST and mental health conditions, and describe mental health utilization among homeless women and men.

**Study Design:** This is a cross-sectional, national study of homeless Veterans who used VHA care between October 1, 2009 and September 30, 2010. All variables were obtained from VHA administrative databases, including homeless status, MST screening, ICD-9-CM codes to determine mental health diagnoses, and VHA utilization. Adjusted logistic regression models were used to examine a Veteran’s likelihood of having a mental health diagnosis by MST history, while adjusting for age, race, ethnicity and marital status. We examined the intensity of mental health utilization by MST history using a generalized estimating equation model with a negative binomial distribution while adjusting for age, race, ethnicity, and marital status.

**Population Studied:** A total of 126,598 homeless Veterans who have utilized VHA care, including 8,915 female and 117,683 male Veterans.

**Principal Findings:** 39.7 percent of female and 3.3 percent of male homeless Veterans in VHA experienced MST. Homeless Veterans who experienced MST demonstrated a significantly higher likelihood of almost all mental health conditions examined as compared to other homeless Veterans, including depression, posttraumatic stress disorder, other anxiety disorders, substance use disorders, bipolar disorders, personality disorders, suicide, and, among men, schizophrenia and psychotic disorders. Nearly all homeless Veterans received mental health services, 97.9 percent of women, and 95.3 percent of men. Veterans who experienced MST utilized significantly more mental health visits compared to Veterans who did not experience MST.

**Conclusions:** A substantial proportion of homeless Veterans using VHA services have experienced MST, and those who experienced MST had increased odds of mental health conditions associated with MST.
diagnoses. Homeless Veterans who had experienced MST had higher intensity of mental health care utilization and high rates of MST-related mental health care.

**Implications for Policy, Delivery, or Practice:** Services to homeless Veterans are a key priority for VHA, and the findings suggest that efforts to engage this population in mental health care appear successful. Our results also underscore that MST is an important clinical issue among this population. This study highlights the importance of trauma-informed approaches to care for this population. It is important that homeless case managers understand how trauma-related issues, including MST, may affect a Veteran's ability to obtain and maintain housing, healthy relationships and employment.

**Results from a Patient-Centered Medical Home Pilot at UPMC Health Plan Hold Lessons for Broader Adoption of the Model**

Cynthia Napier Rosenberg, MD, UPMC Center for High-Value Health Care; Pamela Peele, UPMC Center for High-Value Health Care; Donna Keyser, PhD, MBA, UPMC Center for High-Value Health Care; Sandra McAnallen, BSN, MA, UPMC Center for High-Value Health Care; Diane Holder, MS, UPMC Center for High-Value Health Care

**Presenter:** Pamela Peele, Ph.D., Chief Analytics Officer, Health Economics, UPMC Center for High-Value Health Care, peelepb2@upmc.edu

**Research Objective:** To assess the impact of UPMC Health Plan’s Patient-Centered Medical Home (PCMH) pilot program on cost, service utilization, and clinical quality outcomes for participating practice sites.

**Study Design:** In 2008, UPMC Health Plan instituted a pilot program designed to improve the efficiency and quality of service delivery for its members by providing practice-based care management resources, data sharing, and other supportive services to practices interested in transitioning to PCMHs. Using health plan claims data, we analyzed medical and pharmacy costs, hospital service use, and the percentage of members receiving appropriate care between 2008 and 2010. Using a difference of differences approach, we compared changes for UPMC Health Plan members served by the participating sites to changes for members served by the rest of the plan’s primary care network. To determine the health plan’s return on investment (ROI), we calculated the ratio of net cost avoidance for the program between calendar years 2009 and 2010 and total program costs for the same period.

**Population Studied:** The study included 23,930 adult UPMC Health Plan members (61 percent commercial, 21 percent Medicaid, 11 percent Medicare, and 7 percent Special Needs Plan) who received primary care at the 10 participating practice sites. All of the sites were located in urban settings but varied by size (number of physicians and patients), the proportion of UPMC Health Plan members to total patients served, and use of the UPMC electronic health record and registry software.

**Principal Findings:** Over the two-year study period, participating sites collectively achieved significantly lower medical and pharmacy costs, more efficient service delivery, such as lower hospital admissions and readmissions and less use of hospital emergency departments, when compared with nonparticipating sites. Although there were no significant differences on HEDIS measures between participating sites and the rest of the network between 2008 and 2010, participating sites consistently outperformed the rest of the network on all measures. This performance earned the health plan an average ROI of 160 percent. Seven of the 10 participating sites have since applied for and received recognition as PCMHs under the NCQA’s Physician Practice Connections-PCMH Recognition Program.

**Conclusions:** These results demonstrate the feasibility of improving the efficiency and quality of service delivery by supporting the transition of primary care practices to PCMHs. Positive outcomes can be achieved for adults with various chronic conditions and insured through different products, across multiple practice types, within a short period of time, and with a positive ROI for the payer.

**Implications for Policy, Delivery, or Practice:** Working together, payers and providers at local and regional levels are well positioned to lead the transition toward PCMHs and deliver care that is both high quality and increasingly efficient to all types of patients at all types of practices. Approaches that could spur the adoption and spread of the PCMH model include incentivizing payers to enter into PCMH contracts with interested providers, increasing payers’ efforts to provide primary care practices with access to usable data on their patient populations, and instituting telehealth to connect care managers.
to patients and practices when in-person visits are not possible or necessary.

**Achieving Clairvoyance: Text Mining Electronic Medical Records – Real Meaningful Use**

Scott Zasadil, PhD, UPMC Center for High-Value Health Care; Pamela Peele, UPMC Center for High-Value Health Care; Pamela Peele, PhD, UPMC Center for High-Value Health Care

**Presenter:** Pamela Peele, Ph.D., Chief Analytics Officer, Health Economics, UPMC Center for High-Value Health Care, peelepb2@upmc.edu

**Research Objective:** To determine if a relationship exists between the words in patient-level clinical care notes and a patient’s future use of emergency department or urgent clinic visits. 

**Study Design:** We accessed a proprietary electronic care management platform (Identifi) used by medical care managers at a large health plan (over 2 million covered lives) to record their interactions with health plan members for the purposes of coordinating and managing patient care as well as directing patient interventions and education. Identifi is a member-centric electronic system that contains structured fields as well as a large volume of unstructured free text. Free text notes include care managers’ comments about their interactions with members as well as other care management notes and observations (chronic conditions, medications, caregiver information) and summaries of overall care coordination/management (service authorizations). StatSoft’s Text Miner tool was used to perform text mining. Four hundred unique words appeared in at least 1 percent of the notes and were extracted from this corpus. Associations between important words/phrases were then tested for a statistically significant association with an increase in the cumulative utilization of emergent/urgent care in the 12 months after the date of the note containing the words. To guide the contextual interpretation of the results, discussions were held with the nurses and care managers responsible for documenting in Indentifi. Future use of emergent/urgent care was determined from the place of service identified on the health plan’s medical claims database. 

**Population Studied:** 444,000 clinical records (associated with 66,300 unique members) created in the electronic medical record (EMR) between July and December 2010. The entirety of the clinical note was included. 

**Principal Findings:** Distinct classes of words and phrases exhibited recognizable and significant associations with each other. Some phrases, such as “social worker,” were found to be reliable indicators of a patient’s future use of emergent/urgent care while other words, such as “mother,” were associated with low future use of such care. In these records, the average cost of patients’ emergent/urgent future care use was $6,780 compared to $3,440 when the word “mother” was present and $13,288 when the word “social worker” was present. As a class, notes associated with an inpatient admission were also found to be frequently associated with future emergent/urgent care. Furthermore, the length of the note itself was found to be a simple proxy for predicting future emergent/urgent care.

**Conclusions:** Free text mining (as opposed to natural language processing) of EMRs can create new knowledge about specific words which serve as reliable sentinels of future use of emergent/urgent need for care. 

**Implications for Policy, Delivery, or Practice:** Rapid investment in EMRs by health care providers is producing a large and ever growing body of unstructured textual information. While clearly useful for direct patient care, an additional novel use of these records is the application of text mining to create an entirely new body of knowledge that could not reasonably be produced from paper records. This work illuminates a clear, pragmatic, and compelling way to leverage the ongoing national investment in EMRs for improving patient care and outcomes.

**Provider Office Characteristics Associated with Achieving High-Quality, Affordable Care for Patients Served through the UPMC Health Plan’s Patient-Centered Medical Home Program**

Pamela Peele, UPMC Center for High-Value Health Care; Patty Houck, MSH, UPMC Center for High-Value Health Care
**Presenter:** Pamela Peele, Ph.D., Chief Analytics Officer, Health Economics, UPMC Center for High-Value Health Care, peelepb2@upmc.edu

**Research Objective:** To identify the association between provider office characteristics and health care cost reduction for members and practices participating in the UPMC Health Plan’s Patient-Centered Medical Home (PCMH) program.

**Study Design:** UPMC Health Plan provides practice-based care management services and timely information on members’ quality of care to all practices participating in its PCMH program. Using a panel-data, fixed-effects model, we examined the effect of providing these resources on members’ health care service utilization costs as well as the mediating effect of provider office characteristics on the association between PCMH program participation and costs. Medical and pharmacy costs were analyzed using health plan claims data for the period between July 2008 and March 2012. Provider office characteristics, including specialty composition, NCQA certification through the Physician Practice Connections-Patient Centered Medical Home (PPC-PCMH) Recognition Program, location, size, care management type (onsite versus telephonic), system-owned or independent, and patient composition, were determined through surveillance data compiled by the health plan’s Network Management team and publically-available information on the NCQA website.

**Population Studied:** This study includes 77 practices that participated in the UPMC Health Plan PCMH program between July 2008 and March 2012 and 89,689 unique UPMC Health Plan members who received primary care at these practices. Approximately 60 percent of members were insured through a commercial product; 24 percent through Medicaid; and 17 percent through Medicare. The mean age of members was 42.8 years, and 57 percent were women.

**Principal Findings:** Participation in the UPMC PCMH program has demonstrated a reduction in overall health care costs. Significant practice-level variation in health care costs was observed around financial performance and a relationship was found between significant cost moderation and five specific provider office characteristics, namely NCQA PPC-PCMH certification, serving mainly as a primary care practice, having five or more doctors in the practice, located more than 10 miles from downtown Pittsburgh, and having at least 20 percent Medicaid members.

**Conclusions:** Results suggest that the ability of providers to leverage PCMH resources varies by provider office characteristics. Benefits are most likely to be found among NCQA-certified practices with at least five physicians located outside of major urban areas and serving at least 20 percent publicly-insured patients.

**Implications for Policy, Delivery, or Practice:** In the search for a higher quality, more affordable health care system, PCMH programs have gained momentum and attention as an innovative approach to health care delivery. Health plans, payers, employers, and other organizations seeking to support the implementation of PCMH programs may wish to target resources to those practices that are most likely to be able to leverage those resources into the highest levels of improvement. Attention should be paid to a range of provider office characteristics, including readiness to systematically employ patient-centered, coordinated care management processes, as signified by PPC-PCMH NCQA certification, focus on primary care, number of physicians, patients’ access to care, and patients’ need for care coordination and care management services.

**Comparison of Administrative Data and Electronic Medical Record Data for Use in Pediatric Policy Evaluation**

Robert Penfold, Group Health Research Institute; Karen Hacker, Cambridge Health Alliance; Lisa Arsenault, Cambridge Health Alliance; Shalini Tendulkar, Cambridge Health Alliance; Fang Zhang, Harvard Pilgrim Healthcare Institute

**Presenter:** Robert Penfold, Ph.D., Assistant Investigator, Group Health Research Institute, penfold.r@ghc.org

**Research Objective:** Rigorous policy evaluation (e.g., using interrupted time series analysis) requires defining populations with a stable composition over time. Many investigators use the Medicaid Analytic Extract (MAX) data to conduct such analyses. Our objective was to identify the strengths and weaknesses of claims-based and electronic medical record (EMR-based) data for use in evaluating the impact of state and local policies on youth in safety-net
populations where the composition of the population is often argued to be highly transient.

**Study Design:** We conducted a retrospective cohort analysis in order to compare the demographics, continuity of enrollment, insurance eligibility, and rates of health care utilization obtained from claims-based and EMR-based data systems.

**Population Studied:** The study included children and adolescents aged 4.92 to 18 years and enrolled in Medicaid in two states, Massachusetts and New York and a large pediatric safety-net population (Cambridge Health Alliance) for whom we could access complete EMR data. The study used data collected between Jan. 1, 2001 and Dec. 31, 2008.

**Principal Findings:** We identified several general trends in the annual rates across states between 2001 and 2008. The percentage of individuals coded as “Other” race generally declined over the study period (e.g., NY: 17.2% in 2001 and 5.9% in 2008). The demographic composition across 4 sites within Cambridge Health Alliance was stable. For example, the percentage of White patients was 47.7 in 2002 and 44.2 in 2006. Spanish speakers were 3.4% of the CHA population in 2002 and 4.5% in 2006. At the state level, the percentage of children who qualified for coverage on the basis of age alone generally declined while the percentage who qualified on the basis of poverty increased (e.g., NY: 16.9% in 2001 and 29.0% in 2008). There were also large changes in managed care enrollment and primary care case management over the study period (e.g., NY: 31% in 2001 and 74% in 2008).

**Conclusions:** The demographic composition of the Medicaid and safety net populations was remarkably stable between the two states and 9 years included in this study. However, insurance eligibility (e.g., poverty, SSI, foster care) and managed care enrollment changed dramatically. EMR-based data had the advantage of being more detailed clinically; however, there was a lack of enrollment data to define a continuously eligible cohort. Investigators need to be aware of the various limitations of data collected in order to evaluate any intervention.

**Implications for Policy, Delivery, or Practice:** Evaluation of state and local policies on access, utilization, and clinical outcomes in safety-net populations requires population standardization with respect to eligibility groups and managed care enrollment in order to be valid. Evaluations using EMR-based data must use carefully considered alternatives to “continuous enrollment” such as rolling cohorts of individuals with any health care utilization in the last 12 months.

**Funding Source(s):** NIH

**Poster Session and Number:** A, #100

**Gaps and Opportunities for Quality Measurement in the Management of Schizophrenia in the United States – Avenues for Improved Value in Behavioral Healthcare.**

Grant Picarillo, Avalere Health LLC; Morgan Hanger, Avalere Health LLC; Kristi Mitchell, Avalere Health LLC

**Presenter:** Grant Picarillo, M.S., Senior Associate, Evidence Based Medicine, Avalere Health LLC, gpicarillo@avalerehealth.net

**Research Objective:** For the 1 percent of the US population with schizophrenia, quality of care remains suboptimal. Recent national developments have elevated the conversation about care for the mentally ill, raising awareness about the need for improvement. One increasingly popular way to promote effective care across many therapeutic areas is measuring and rewarding providers for patient outcomes. Recognizing that the complex patient population and variable disease progression may make outcome-based measurement especially difficult in this space, Avalere sought to understand the current measurement landscape for schizophrenia and to identify potential areas for improvement.

**Study Design:** Using publicly available sources, Avalere compiled US-based schizophrenia measures, capturing both their endorsement status and implementation in quality measurement programs. To determine where gaps existed, measures were mapped against a care continuum based on our analysis of leading schizophrenia guidelines (e.g., American Psychiatric Association, The Schizophrenia Patient Outcomes Research Team, Magellan Health Services, and The Texas Medication Algorithm Project). Avalere first determined whether existing measures assessed the most meaningful aspects of care, and subsequently evaluated gap areas to determine if they were linked either to a lack of necessary evidence or lack of an existing measure concept.

**Population Studied:** NA

**Principal Findings:** Avalere indentified 43 schizophrenia measures developed by both
private and public entities. The majority (44 percent) focus on clinical processes/effectiveness, while a smaller percentage focuses on care coordination (23 percent) and patient and family engagement (23 percent). The remaining measures address patient safety (7 percent) and efficient use of healthcare resources (3 percent). Across these topic areas, only 4 (11 percent) assess a patient outcome. Over half of schizophrenia measures (23 in number, including 2 of the outcomes measures) are currently used in prominent public or private quality improvement initiatives. Measure gaps appear across the care continuum, with few measures addressing screening and diagnosis, clinical outcomes, episode of care, quality of life, and shared decision-making, despite an evidence base in many of these areas. While some measures speak to aspects of care coordination, few meaningfully incent effective patient management (e.g. care planning across facilities and communities) to encourage more supportive, continuous treatment for patients with schizophrenia.

Conclusions: Current schizophrenia measures do not adequately address many care stages that are critical for the successful management of schizophrenia, despite an evidence base that could support such measures. Furthermore, although some measures assess concepts elemental to high quality care, a disproportionate number focus on intermediary processes, revealing an opportunity to develop and deploy more robust measures related to patient outcomes.

Implications for Policy, Delivery, or Practice: As the national dialogue about more comprehensive care for mental health patients grows louder, stakeholders will explore many ways to improve the effectiveness of treatment; careful measure development and implementation may be one piece of the puzzle. Additional care improvement models such as behavioral health medical-homes may marry nicely with targeted measurement to achieve better clinical outcomes in schizophrenia, both by emphasizing smooth care transitions between providers and within communities, and by focusing care more directly on appropriate and achievable patient-level outcomes.

Emergency Department Boarding of Admitted Patients

Stephen Pitts, Emory University; Marc M. Gautreau, University of Massachusetts Medical School; Frances L. Vaughn, Emergency Care Coordination Center, Ass't Sec'y for Preparedness and Response; Graydon Lord, Emergency Care Coordination Center, Ass't Sec'y for Preparedness and Response

Presenter: Stephen Pitts, M.D., M.P.H., Associate Professor, Emergency Medicine, Emory University, srpitts@emory.edu

Research Objective: Boarding of inpatients in the emergency department (ED) has been identified by the Government Accountability Office and the Institute of Medicine as the principal cause of ED crowding, and has led to new Centers for Medicare and Medicaid Services (CMS) reporting mandates. However, nationally representative estimates of boarding prevalence and duration have not been available until now. We analyzed new boarding-related items in the National Hospital Ambulatory Medical Care Survey (NHAMCS).

Study Design: Serial cross-sectional samples that use multi-stage, stratified design, with sampling weights and design variables supplied by the National Center for Health Statistics in online public-use files. Individual ED identity is masked, but an ED identifier code and ED-level sampling weights are provided in recent files, allowing analysis by ED as well as by visit. Our ED-level analyses used the year 2010 only, because ED identifier codes changed between years; visit-level analyses use surveys from 2009-2010; and institutional boarding questions were available for the years 2007-2010.

Population Studied: The 2010 NHAMCS is a nationally representative sample of ED visit data abstracted from clinical records. Data include an indicator for hospital admission and a duration of boarding in minutes, defined as the time between bed request and actual departure from the ED. Of 4628 hospital admissions sampled in 2010, 3422 (74%) reported a boarding time.

Principal Findings: From 2007 to 2010 there was a decrease from 64 to 55 (p=0.087) in the percentage of EDs that reported sometimes boarding hospital admissions for more than 2 hours. During the same period the percentage of EDs that moved boarded patients to other areas of the hospital like non-ED hallways, the so-called “full capacity” policy, increased minimally, from 16 to 25 (p=0.025). Boarding duration
(2009-2010) was markedly skew in the weighted sample, with a mean of 127 minutes and a median of 79 (IQR 36 to 145). The percentage of admissions boarded more than 2 hours was 32 (95% CI 30 to 35), and for more than 4 hours was 10 (95% CI 9 to 12). Visit-level predictors of “boarding more than 2 hours” included older age, arrival during office hours, ambulance arrival, advanced imaging, and “seen by resident or intern”. We divided EDs into quartiles based on median boarding duration. The EDs in the highest quartile of boarding saw 41 percent of ED visits, and the highest two quartiles together saw 73 percent, implying an association between ED volume and boarding duration. Specific visit volumes are not disclosed in public-use files. In an ED-level multivariable linear regression on log-transformed median boarding duration, ED characteristics independently associated with longer boarding included a higher proportion of visits by non-Hispanic blacks, the Northeast geographic region, and urban location.

Conclusions: We have described the new ED boarding items in the NHAMCS, and determined which ED factors are associated with median boarding time.

Implications for Policy, Delivery, or Practice: The use of median boarding duration as a CMS “core measure” incentive may unintentionally reward some EDs for characteristics beyond their control, like lower visit volumes.

Funding Source(s): Other, HHS/ASPR/OPEO/ECCC

Poster Session and Number: A, #102

Price Variation for Colonoscopy in a Commercially Insured Population
Alexis Pozen, UC Berkeley

Presenter: Alexis Pozen, BA, Graduate Student, Health Services and Policy Analysis, UC Berkeley, apozen@berkeley.edu

Research Objective: We aimed to quantify the variation in prices for colonoscopy in a concentrated geographic region, as well as to evaluate whether market competitiveness was associated with this variation.

Study Design: We retrospectively analyzed the fee-for-service prices - defined as allowed amount - paid by a large Midwestern commercial insurer for a colonoscopy to hospital outpatient departments [HOPDs] and ambulatory surgery centers [ASCs] in a geographic region spanning part of two states. To mitigate outlier bias, we report results excluding the top and bottom one percent of prices. We conducted multivariate regressions of log price on varying tests of market competitiveness, controlling for current procedure terminology [CPT] code and facility [HOPD or ASC] and month fixed effects. Standard errors in each case were heteroskedasticity-robust and clustered at the county level.

Population Studied: We studied 110,907 claims from 101,769 commercially insured adults 18 and older who underwent outpatient colonoscopy in 138 HOPDs and 18 ASCs between 2005 and 2010.

Principal Findings: The mean price of a colonoscopy across facilities was 1,789 dollars at a HOPD [SD = 572], with a minimum price of 270 dollars and a maximum of 10,261 dollars. The mean price at an ASC was 1,324 dollars [SD = 115.6], with a minimum price of 318 dollars and a maximum of 2,930 dollars. ASCs had significantly lower mean prices than HOPDs [p less than 0.001]. Colonoscopy price increased with expected reasons [advancement in time, more complex CPT codes]. Although the coefficients on the variables of interest, the market competition variables, were all in the expected direction, they were all very small and statistically insignificant: number of facilities in the county [-0.0040, SE=0.0059]; market share based on number of colonoscopies performed [3.56e-06, SE=0.0002]; county Hirschman-Herfindahl Index, the sum of squared colonoscopy market shares [-1.28e-06, SE=3.00e-06].

Conclusions: There is substantial variation in the price paid for a colonoscopy in the Midwestern region studied. Our analysis tested whether market competition was associated with this price variation using several definitions of competitiveness, but we did not find evidence of a link between the two for the procedure studied.

Implications for Policy, Delivery, or Practice: While spending variation for Medicare patients is well-documented, new data are beginning to show that such variability exists for commercial patients as well, reflecting not only variability in utilization but also price. In health care, high prices do not always reflect high quality but a host of other reasons, including concentrated provider markets and lack of transparency to both consumers and other providers. This study has aims to shed light on both the extent of pricing variability for a relatively straightforward procedure as well as some explanations for why it exists, an area that is just beginning to be
Complex Comorbidity Clusters: A Cross Section Assessment of Healthcare Utilization

Mary Jo Pugh, South Texas Veterans Health Care System; Erin P. Finley, South Texas Veterans Healthcare System; Polly H. Noel, South Texas Veterans Healthcare System; Laurel A. Copeland, Central Texas Veterans Healthcare System; Chen-Pin Wang, University of Texas Health Science Center San Antonio; Jacqueline A Pugh, South Texas Veterans Health Care System

Presenter: Mary Jo Pugh, Ph.D., R.N., Research Health Scientist/Assistant Professor Of Medicine, VERDICT REAP, South Texas Veterans Health Care System, pughm@uthscsa.edu

Research Objective: Studies that describe physical or mental conditions among Veterans from Afghanistan and Iraq (OEF/OIF/OND) have focused primarily on the Polytrauma Clinical Triad: Traumatic Brain Injury (TBI), Post-traumatic Stress Disorder (PTSD), and chronic pain. The purpose of this study was to identify clusters of deployment-related, and chronic conditions in an OEF/OIF/OND cohort.

Study Design: We used VA inpatient, outpatient, and pharmacy data to identify OEF/OIF/OND veterans receiving VA care FY08-09, and identify conditions associated with TBI, blast injury, chronic pain, and chronic diseases using previously validated algorithms. We developed hierarchical clusters based on presence or absence of specific conditions. We used latent class analysis to identify latent classes of co-occurring comorbidity and labeled those based on conditions that are most common in the class. We then describe characteristics including healthcare utilization in FY10 by latent class.

Population Studied: Veterans of Afghanistan/Iraq wars who received VA care.

Principal Findings: We found six latent classes. The first two fit the pattern of polytrauma clinical triad; the first had twice the likelihood of pain diagnoses as the second, while the second had twice the likelihood of TBI diagnosis. Class three had high likelihood of mental health and substance use disorders. Class four had 100% likelihood of sleep disorders, with high likelihood of hypertension and amputation diagnoses. Class five was characterized by pain (excluding headache) and chronic disease. Class six was relatively healthy. Mental Health care and suicide related behaviors were more common in Classes 1-4; Pain, orthopedic/neurosurgery were more common in Class 5.

Conclusions: Distinct classes of comorbidity clusters were revealed in this cross-sectional cohort, and healthcare utilization, particularly for mental health, was very common in this cohort.

Implications for Policy, Delivery, or Practice: Assuring adequate access to mental health care is of critical importance in this population where suicide related behavior is increasing over time.

Treatment Costs of Advanced Cancer: Variation in Costs for Stage IV vs. Recurrent Breast, Colorectal, Lung, and Prostate Cancers

Presenter: Debra Ritzwoller, Ph.D., Health Economist, Institute for Health Research, Kaiser Permanente Colorado, debra.ritzwoller@kp.org

Research Objective: Advanced cancer results in the bulk of cancer-related deaths, morbidity, and expenditures. Previous studies have described the variation in utilization and costs associated with cancer patients diagnosed at late stage vs. early stage. Other studies have described the high cost of cancer care in the terminal phase. Little is known regarding variation of costs of advanced cancer care between patients diagnosed de novo with stage IV cancer versus those with recurrent metastatic cancer that develops after definitive therapy for early-stage disease and a period of disease-free survival. We evaluate medical care costs and resource use during the year after development of metastatic disease among patients presenting with stage IV disease and
versus those with metastatic recurrence, using data from two Cancer Research Network (CRN) HMOs with tumor registries that capture recurrence, adjusting for patient and tumor characteristics.

**Study Design:** Retrospective cost analysis comparing treatment costs of patients diagnosed with stage IV versus metastatic recurrent, breast, colorectal, lung, or prostate cancer. Patients were followed for twelve 12 months following diagnosis date (or through the end of 2008, or death, or disenrollment). Patient and tumor characteristics, comorbidities, utilization, and mortality were obtained from the Virtual Data Warehouses (VDW) from two HMOs (Kaiser Permanente Colorado and Kaiser Permanente Northwest) who participate in the CRN. Estimates of costs were derived from the CRN “Standardized Relative Resource Cost Algorithm” (SRRCA) by adapting these systems to assign real (deflated) costs that are based on CMS fee schedules that are mapped to VDW event-specific diagnostic and procedure data (DRGs, ICD-9-CM, HCPCS CPT, etc.). Descriptive statistics and multivariate regression analyses were used to compare costs and resource use.

**Population Studied:** Patients aged > 21+ years and HMO-enrolled/insured at the two CRN sites who were diagnosed with stage IV or recurrent metastatic breast (n = 383), colorectal (n = 752), lung (n = 1,463), or prostate (n = 364) cancer, between 2000-2007, were included in the analysis.

**Principal Findings:** 40% of patients were under age 65. Age at diagnosis was significantly lower for patients with stage IV (vs. recurrent) colorectal (66.4 vs 68.2, p = .05) cancer, and significantly higher for stage IV lung (68 vs 66 p = .02) and prostate (69.5 vs 62.8) cancers. Relative to patients with recurrent disease, stage IV colorectal and lung cancer patient had a significantly lower (p < .0001) comorbidity scores. Stage IV breast cancer patients had the highest annual treatment cost ($57,506) and recurrent prostate cancer patients had the lowest ($23,876). Adjusted marginal annual treatment costs were significantly higher for patients diagnosed with stage IV breast ($21,000, p = .0005) and colorectal ($13,500, p < .0001) cancers, relative to patients diagnosed with recurrent disease. No significant differences were found for lung and prostate stage IV vs recurrent cancers.

**Conclusions:** The findings from this analysis could have significant clinical and policy relevance related to the cost implications of treating advanced cancer.

**Implications for Policy, Delivery, or Practice:** Higher costs for de novo vs. recurrent advanced stage disease should be examined from a clinical quality perspective with a focus on comparative effectiveness of initial and end-of-life care.

**Improved Trends in VA Facilities in Best Practices for Heart Failure: VA CHF QUERI**

Anju Sahay, Veterans Affairs Palo Alto Health Care System; Paul Heidenreich, MD, MS, Dept. of Veterans Affairs

**Presenter:** Anju Sahay, PhD, Research Health Science Specialist, CHF QUERI, Veterans Affairs Palo Alto Health Care System, anju.sahay@va.gov

**Research Objective:** Heart failure (HF) has been the number one reason for admission among Medicare patients and those in the Veterans Affairs (VA) Health Care System. Through multi-level and multi-facility evidence-based interventions, the Chronic Heart Failure (CHF) QUERI, has been facilitating best practices for HF care at all the VA facilities. Mortality for patients with heart failure has been improving but it is unclear if this has been associated with improved processes of care. The goal of this study was to assess changes in the structures and processes of HF care from 2008 to 2011 at all the VA facilities.

**Study Design:** Using a longitudinal approach in 2008 the CHF QUERI identified facility-level best practices for improved HF care.

**Population Studied:** In 2008 and then again in 2011 cross-sectional surveys were completed by the Chiefs of Medicine or Chiefs of Cardiology at each VA facility. For both waves of data collection we had a response rate of 100% from 140 facilities.

**Principal Findings:** Significant improvements were observed from 2008 to 2011 across structures and processes of care at the VA facilities. For facilities reporting no use of the following processes of care in 2008 consistent increases were seen in the presence of clinics with a HF focus (22%); use of a protocol for diuretic titration by providers (25%) and by patients (14%); use of HF educational materials (56%) and home-monitoring (53%); and involvement of pharmacists (54%) and dieticians.
Are Discharge Policies Now Better for Hospitalized Heart Failure Patients? VA CHF QUERI
Anju Sahay, Veterans Affairs Palo Alto Health Care System; Paul Heidenreich, MD, MS, Dept. of Veterans Affairs

Presenter: Anju Sahay, PhD, Implementation Research Coordinator, CHF QUERI, Veterans Affairs Palo Alto Health Care System, anju.sahay@va.gov

Research Objective: Over the past few years the VA Chronic Heart Failure (CHF) QUERI has been facilitating national initiatives like the Save 5 Million Lives Campaign and Hospital To Home (H2) with specific focus on inpatients, discharge process and follow up HF care. Survival following discharge has improved though it is not clear if discharge policies have changed.

Study Design: Using a longitudinal approach in 2008 the CHF QUERI identified facility-level best practices related to discharge processes for hospitalized HF Veterans.

Population Studied: In 2008 and then again in 2011 cross-sectional surveys were completed by the Chiefs of Medicine or Chiefs of Cardiology at each VA facility. For both waves of data collection we had a response rate of 100% from 140 facilities.

Principal Findings: Comparative findings over the 3 years show that VA facilities have markedly improved their discharge policies for hospitalized HF patients. Among the facilities reporting none of the following discharge policies in 2008, in 2011 53% of those facilities routinely schedule a follow-up phone call after discharge within <1 week (59%) and >1 week (41%); and 100% of those facilities routinely scheduled a follow-up visit with provider at the time of discharge within <1 week (83%) and >1 week (17%).

In 2011 facilities reported that during the first follow-up visit with provider after discharge the HF patient is usually seen in HF clinic (41%), by cardiology provider not in HF Clinic (19%), by primary care provider (37%) and other (3%).

Conclusions: Significant improvements in the discharge policies of hospitalized HF patients at VA facilities have occurred from 2008 to 2011.

Implications for Policy, Delivery, or Practice: Improved discharge HF care may have contributed to the reduction in 30-day mortality.

Funding Source(s): VA

Developing a Heart Failure Toolkit for Providers: VA CHF QUERI
Anju Sahay, Veterans Affairs Palo Alto Health Care System; Paul Heidenreich, MD, MS, Dept. of Veterans Affairs

Presenter: Anju Sahay, PhD, Research Health Science Specialist, CHF QUERI, Veterans Affairs Palo Alto Health Care System, anju.sahay@va.gov

Research Objective: Reducing readmission rates for heart failure (HF) patients is the primary goal of the Department of Veterans Affairs (VA) and its Chronic Heart Failure (CHF) QUERI Center. Since its establishment in 2005 the CHF QUERI has undertaken many initiatives to improve the quality of HF care by providers for veterans. One such initiative is the forming of the Heart Failure (HF) Provider Network which currently consists of over 800 members (providers) at all the 150 VA facilities. These providers are Chiefs of Cardiology, Chiefs of Medicine, Chiefs of Staff, cardiologists, physicians, nurse practitioners, nurses, pharmacists, telehealth coordinators, facility-level leadership, VISN (region)-level leadership, and others.

With the growing number of VA’s collaboratives and its Central Office’s initiatives like the Patient Aligned Care Teams (PACT) it is important for operations, staff and providers to have access to evidence-based tools for the management of heart failure patients for improved outcomes. Based on input and collaboration with the HF Network as the key stakeholder, recently the CHF QUERI developed a comprehensive evidence-based “Heart Failure (HF) Toolkit for Providers”.

Funding Source(s): VA
Study Design: This is a web-based toolkit with links and downloadable PDF documents.

Population Studied: Here the focus is on HF care. This toolkit has been developed through collaboration with the members of its HF Network as well as non-VA organizations. These tools are organized as tools from VA Sources, Non-VA Sources: Other; and Non-VA Sources: GWTG-AHA (Get With The Guidelines - American Heart Association). The tools can be used by providers, operations, patients and caregivers.

Principal Findings: This toolkit focuses on several key areas in the management of heart failure like mortality risk models, practice guidelines, clinical pathways, clinical algorithms, screening forms, admission and discharge order sets and instructions, best practices, and education materials for providers, patients and caregivers. This toolkit has been developed through the collaboration of HF Network members as well as non-VA organizations. Tools are organized as provided by VA Sources, non-VA Sources (Other) and non-VA Sources (American Heart Association’s Get With the Guidelines Program). Ongoing formative evaluation of the toolkit includes suggestion box for sharing tools, evaluation of the downloaded tool and comments.

This toolkit is being disseminated within the VA through the HF Network and VA Program Offices. Outside the VA it is being uploaded as a quality tool on AHRQ Health Care Innovations Exchange website and has been provided to the National Hospital to Home (H2H) initiative focusing on reducing heart failure readmissions.

Conclusions: Providers and staff are finding such a toolkit extremely valuable for the management of heart failure patients.

Implications for Policy, Delivery, or Practice: Evidence-based comprehensive, well-organized and easily accessible resources are very helpful for improved outcomes of heart failure patients.

Poster Session and Number: A, #108

Combining Population Health Surveys and Administrative Data to Promote Coordination and Accountable Care

Michael Sajovetz, State of Colorado; Alyson Shupe, Colorado Department of Public Health and Environment

Presenter: Michael Sajovetz, M.A., Statistical Analyst, Health Care Policy and Financing, State of Colorado, michael.sajovetz@state.co.us

Research Objective: This project demonstrates how combining Medicaid claims data with public health survey data can highlight opportunities for integrating behavioral and physical health care in the context of the Accountable Care Collaborative (Colorado Medicaid’s Accountable Care Organization). Furthermore, it draws attention to areas in which the Regional Care Collaborative Organizations, which are responsible for care coordination for Medicaid beneficiaries one of seven regions in the state, can align their efforts with the various recipients of the nearly $400 million Colorado has received through Affordable Care Act-related funding.

Study Design: At the beginning of the Hickenlooper administration, the Colorado Departments of Health Care Policy and Financing, Public Health and Environment, and Human Services worked to identify ten “winnable battles” to improve public health. In the two years since these areas were identified, the three departments have collaborated to develop key health indicators across various data sources to address each of these battles. Many of the indicators identified are measurable using data from the CDC’s Behavioral Risk Factor Surveillance System, Colorado’s supplemental Child Health Survey, and Medicaid administrative claims and enrollment data.

Measures pertaining to the prevalence and potential cost of concurrent mental health and chronic physical health conditions were aggregated for each RCCO. In addition to prevalence and cost estimates, data was collected showing how much ACA funding has already been distributed to public and private organizations in each region of the state, and the activities these organizations are engaged in to integrate behavioral and physical care.

Population Studied: Data from the 2011 public health surveys was aggregated for three main groups of interest: current Medicaid beneficiaries, people likely to be eligible for the Medicaid expansions of 2014 based on self-reported income level and insurance status, and people expected to participate in the private insurance market, either through the health insurance exchange or through employer-sponsored insurance.

Medicaid administrative data was aggregated for all beneficiaries eligible in state fiscal year 2011-12. Particular attention was paid to those beneficiaries who utilized both behavioral and physical health services and have a “dual
diagnosis" of severe mental illness and chronic physical health conditions.

**Principal Findings:** The end result of this project is a series of Locality Health Profiles, specific to each one of the seven RCCOs in the state. These profiles show what key opportunities for integrating behavioral and physical health care exist, and what activities are already underway to support integrative efforts.

**Conclusions:**

**Implications for Policy, Delivery, or Practice:** Accountable Care Organizations are widely believed to be a solution to the problem of fragmented behavioral and physical health care systems, but there is little consensus regarding how that integration will occur. Combining public health surveys and administrative data can show where the most fruitful opportunities lie. Furthermore, Colorado Medicaid’s regional approach to accountable care allows for efforts to potentially be aligned not only at the state level, but also between state agencies, local health departments, and private entities.

**An Iterative, Community Feedback-Driven Approach to Household Survey Design**

Lujia Zhang, Medicine, UCLA; Ibrahima Sankare, UCLA; Arleen Brown, UCLA GIM HSR; Keyonna King, UCLA Medicine; Ibrahima Sankare, UCLA Medicine; Katherine Kahn, UCLA Medicine; D’Ann Morris, Los Angeles Urban League; Loretta Jones, Healthy African American Families; Nell Forge, Charles Drew University

**Presenter:** Ibrahima Sankare, M.H.A, Research Associate II, Medicine, UCLA, isankare@mednet.ucla.edu

**Research Objective:** While household surveys are common in epidemiologic research, few studies have employed community partnered participatory research (CPPR) in the research design phase. CPPR is a process in which community and academic partners are valued equally and collaborate jointly in research development, implementation, and dissemination. The Healthy Community Neighborhood Initiative (HCNI) is a collaborative effort between the Los Angeles Urban League, and Healthy African American Families (HAAF), Charles Drew University, and University of California in Los Angeles (UCLA) to improve health and health care in a South Los Angeles community disproportionately affected by preventable chronic conditions. Community-academic input informed survey development and study design to build capacity for community engaged research to reduce health disparities.

**Study Design:** HCNI members identified key topics for the interview and examination and then iteratively ranked items, refined and piloted elements of the survey and clinical examination; obtained community input on the informed consent form, the survey, and the clinical and laboratory data collection protocols; and piloted household surveys. After each household visit, observer and participant recommendations were incorporated into the protocol for the next visit.

**Population Studied:** The HCNI aims to improve the health and health care of Latino and African American populations residing in South Los Angeles.

**Principal Findings:** enhanced participant understanding of the informed consent form (ICF) and survey questions, reduced time spent “in-home” by 30 minutes, and streamlined the protocol to facilitate fewer surveyors in the household.

**Conclusions:** An iterative, community-academic feedback-driven revision process resulted in substantive changes to the ICFs, surveys, and data collection protocols that reflected the unique characteristics of the community and its residents. By emphasizing community engagement early in the study design phase, we established bidirectional knowledge exchange between researchers and the community.

**Implications for Policy, Delivery, or Practice:** An iterative process of eliciting and incorporating feedback from study participants and a diverse group of community and university-based team members resulted in improvements to the survey content and protocol that streamlined the survey process and made it easier for participants to understand study procedure and findings. This framework can help to examine the impact of incremental changes in CPPR protocols on study processes and outcomes.

Community Partnered Participatory Research as an Effective Method for Developing New Paradigms for the Recruitment and Retention of Underrepresented Populations in Medical Research

Ibrahima Sankare, UCLA; Rachelle Bross, Harbor-UCLA Medical Center; Los Angeles Biomedical Research Institute; Arleen Brown, UCLA Medicine; Katherine L. Kahn, UCLA Medicine; Keyonna King, UCLA Medicine; D’Ann Morris, Los Angeles Urban League; Loretta Jones, Healthy African American Families; Roberto Vargas, UCLA Medicine

Presenter: Ibrahima Sankare, M.H.A., Research Associate II, GIM-HSR, UCLA, isankare@mednet.ucla.edu

Research Objective: Low levels of recruitment, retention and participation of minority populations in medical research studies hinder efforts to address and reduce ethnic and racial disparities in health care and health status. As part of the Healthy Community Neighborhood Initiative (HCNI) community-partnered study that aims to improve health and health care in a community in South Los Angeles, we (1) identified barriers to participation of minority populations in research, and (2) identified effective recruitment and retention strategies for use with predominantly African American and Latino residents in South Los Angeles.

Study Design: Using the PubMed database, we conducted a literature review and found 20 articles specifically related to the recruitment and retention of federally underrepresented minorities (African Americans/blacks, Latinos/Hispanics). We evaluated each article based on: (1) the use of a CPPR process to design the recruitment and retention strategies, (2) the effectiveness of reported strategies in yielding positive outcomes in a predominantly Latino and African American populated area, and (3) the effectiveness of these strategies in generating trust among these demographics that have historically mistrusted health-related studies due to negative historical precedents. The findings of the selected articles were summarized in an oral presentation to community and academic partners. To reflect the diversity of the HCNI partners in the selection of recommended strategies, 13 HCNI community and academic partners subsequently ranked each of the identified strategies. The HCNI partners then applied the highest ranked strategies to recruitment efforts in South Los Angeles and queried enrolled study participants about what motivated their study participation.

Principal Findings: We identified 10 recruitment and 17 retention strategies that had been proven to increase participation of underrepresented populations in medical research by maximizing the quality of a research participant’s experience through (1) meaningful interactions with study team members, (2) demonstration of appreciation for the participant’s efforts and (3) the provision of feedback throughout and upon the completion of the research study. The three highest ranked recruitment strategies were: word of mouth, use of newsletters, and postings of fliers on bulletin boards. The highest ranked retention strategies were: compensation through gift cards, mailing of holiday cards, and provision of certificates of study completion. To date, the HCNI partners have contacted 90 potential participants and enrolled 79 participants using a combination of the cited strategies. Sixty percent of the enrolled participants cited word of mouth as the strategy that most motivated their interest in study participation.

Conclusions: CPPR provides an extraordinary opportunity to identify relevant and effective mechanisms for recruiting underrepresented populations. After applying recruitment strategies supported by the literature and by a diverse set of community-academic partners, we learned from enrolled study participants that “word of mouth” involving personal interaction was the most effective recruitment strategy in this community.

Implications for Policy, Delivery, or Practice: While initially, this recruitment strategy may cause selection bias as we disrupt the mistrust barrier, with time, the development of trust between community and academia is likely to facilitate building a highly engaged and unbiased population-based sample.

Impact of Teaching Intensity and Academic Status on Medical Resource Utilization by Teaching Hospitals in Japan

Daisuke Sato, The University of Tokyo Hospital; Kiyohide Fushimi, Health Policy and Informatics Section, Department of Health Policy, Tokyo Medical and Dental University Graduate School
Research Objective: In this study, we aimed to quantitatively determine the impact of teaching intensity and academic status on medical resource utilization, by analyzing administrative data from teaching hospitals in Japan.

Study Design: Administrative data for 47,397 discharges from 40 academic and 12 non-academic teaching hospitals in Japan were collected. Hospitals were classified into three groups according to intern/resident-to-bed (IRB) ratio. Resource utilization of medical services was estimated using fee-for-service charge schedules and normalized with case mix grouping. Hospitals were classified into three groups according to the IRB ratio in 2004, which represented the teaching intensity: low IRB (IRB < 0.02, LIRB), medium IRB (0.02 = IRB < 0.05, MIRB), and high IRB (IRB = 0.05, HIRB).

The number of residents was based on the list of residency matching program used by Japan’s Residency Matching Program. Relative medical resource utilization for each patient was determined according to the fee-for-service charge schedule, which is a good estimate of healthcare costs because there is a high correlation between the cost and the charge [29]. Case-mix adjustments by the DPC code group were performed as follows: first, for each DPC code group, the average fee-for-service charge value for service categories such as laboratory tests, radiological examinations, and so on, was calculated. Next, relative medical resource utilization for each service category of each patient was calculated as the charge value of the service category divided by the average charge value for the DPC code group of the patient. Relative medical resource utilization was calculated for laboratory tests, radiological examinations, injections, medications, non-surgical procedures, and surgical procedures. Similarly, the case-mix-adjusted relative average length of hospital stay (ALOS) was calculated.

This study was approved by the ethics committee of Tokyo Medical and Dental University. Age was stratified into two categories on either side of 65 years of age. Charlson’s comorbidity index was classified into five groups (0, 1, 2, 3, 4 or more). The significance of differences was determined using the two-tailed t-test. In multivariate regression analysis, to examine the effects of teaching intensity, which presumably represents activities for postgraduate training, and academic status, which represents functions such as medical research and undergraduate teaching, on relative medical resource utilization, sex, age category, Charlson’s comorbidity index and relative intensity of surgical procedures for each case were used as control variables to adjust for case mix differences. The relative intensity of surgical procedures was calculated as follows: first, for each DPC code group, the average fee-for-service charge value for surgical procedures was calculated. Next, the relative intensity of surgical procedures of each patient was calculated as the charge value of surgical procedures of the patient divided by the average charge value of surgical procedures for the DPC code group of the patient. An independent effect of teaching intensity and academic status was assumed and the potential interaction of the two factors or hospital clustering effect was ignored owing to limitation of the data. All analyses were performed using SPSS Software (version 12.0; SPSS, Inc., Chicago, IL). A twosided p value < 0.05 was considered statistically significant.

Population Studied: The data used in this study were collected electronically from hospital administrative records for the period from July through October 2004, and these were obtained from 40 national university academic teaching hospitals, which provide medical research and undergraduate medical teaching in addition to postgraduate training, and 12 non-academic teaching hospitals, which simply provide postgraduate training, in Japan. The data were voluntarily offered to our study group. The hospitals were located in different parts of the country and provided postgraduate medical education for more than two years, prior to the alteration of the postgraduate medical education system in 2004.

These data included International Classifications for Diseases and Related Conditions Version 10 (ICD10) codes for primary diagnosis, comorbidities and complications, and demographics, as well as the daily utilization of procedures, medications, and materials. A 14-digit Diagnosis Procedure Combination (DPC) code, which was assigned to each patient record for per-diem prospective payment based on primary diagnosis, comorbidities, and procedures as described elsewhere, was used for case mix adjustment. Charlson’s comorbidity index was calculated from 12 diagnostic data fields.
Principal Findings: 15–24% more resource utilization for laboratory examinations, radiological imaging, and medications were observed in hospitals with higher IRB ratios. With multivariate adjustment for case mix and academic status, higher IRB ratios were associated with 10–15% more use of radiological imaging, injections, and medications; up to 5% shorter hospital stays; and not with total resource utilization. Conversely, academic status was associated with 21–33% more laboratory examinations, radiological imaging, and medications; 13% longer hospital stays; and 10% more total resource utilization. We found that high teaching intensity was associated with more resource utilization for radiological imaging, injections, and medications, but less hospital stays and, in consequence, did not have any significant effect on total resource utilization. In contrast, academic status was associated with more resource utilization for laboratory examination, radiological imaging, medications, and hospital stays, resulting in an approximate 10% more total resource utilization.

Conclusions: While differences in medical resource utilization by teaching intensity may not be associated with indirect educational costs, those by academic status may be. Therefore, academic hospitals may need efficiency improvement and financial compensation.

Implications for Policy, Delivery, or Practice: As for health policy implications, on the basis of resource utilization patterns, our results may indicate that financial compensation for teaching activity does not need to be large. Instead, our result may imply the necessity of health policy measures for excess costs in academic teaching hospitals. The mechanisms behind the remarkable difference in resource utilization between academic and non-academic teaching hospitals were unclear from our analysis. Inefficiency of inpatient care owing to inadequate oversight or the inexperience of residents may partially account for this difference. In addition, the poor management capability of university hospitals may potentially account for their inefficiency. This inefficiency need not be compensated by health-care payments, and the introduction of guidance for hospital management or fair market competition will hopefully improve their efficiency. Alternatively, it is conceivable that more medical resource utilization may arise from the superior setting and resources in academic hospitals, including easily accessible tests for teaching purposes [11], on-site clinical research, and standby capacity for specialized patient care. In addition, incomplete case mix adjustment, which may hardly be perfect even with refined case mix classification system, for sicker patients in academic hospitals may account for their excess costs. For these kinds of excess costs, financial supports for academic medical hospitals or further refinement of the case mix system will need to be acknowledged.

Poster Session and Number: A, #112

Increases in the Rate of Pediatric Epilepsy Surgery Following Evidence-Based Guidelines
Nicholas Schiltz, Case Western Reserve University; Elia Pestana-Knight, University Hospitals Case Medical Center; Paul Bakaki, Case Western Reserve University; Siran Koroukian, Case Western Reserve University; Kitti Kaiboriboon, University Hospitals Case Medical Center

Presenter: Nicholas Schiltz, BS, PhD student, Epidemiology & Biostatistics, Case Western Reserve University, nicholas.schiltz@case.edu

Research Objective: Epilepsy surgery is safe and effective and can lead to significant improvements in quality of life for persons with medically uncontrolled epilepsy, but utilization remains low. Evidence-based guidelines published in 2003 called for referral of these patients for evaluation as possible surgical candidates, but studies have shown no significant increase in utilization of surgery among adults. Temporal trends in the rate of pediatric epilepsy surgery have not been investigated at the population level.

Study Design: Retrospective cross-sectional study using the Kids Inpatient Database from 1997, 2000, 2003, 2006, and 2009. Annual estimates of the number of pediatric epilepsy surgical procedures were derived using sample weights. Subgroup variables of interest include age group, gender, race/ethnicity, and primary payer, hospital characteristics, and surgery type. Annual rates of epilepsy surgery per 1000 person-years were calculated using published prevalence estimates of pediatric epilepsy as the denominator. Linear regression was used to test for changes in rates over time.
**Population Studied:** Children age 0 to 17 with epilepsy in the United States

**Principal Findings:** The rate of epilepsy surgery increased steadily from 1997 (0.83 surgeries / 1000 person-years) to 2000 (0.87/1000), 2003 (1.24/1000), 2006 (1.43/1000), and 2009 (1.48/1000). The rate of surgery increased from 1997 to 2009 across all age groups, race categories, gender, and payer types. Rates were lowest among blacks compared to whites (0.62/1000 vs. 1.20/1000 in 2009), Medicaid-enrolled compared to private payers (0.71/1000 vs. 2.03/1000 in 2009), and males (1.26/1000 vs. 1.81/1000 in 2009) in all years. Overall utilization of epilepsy surgery remained low as the range in number of cases per year was 375 (1997) to 706 (2009). The majority of procedures took place at children’s hospitals (range: 84% - 100%), and teaching hospitals (85% - 97%).

**Conclusions:** Rate of change in pediatric epilepsy surgery in USA increased from 1997 to 2009 across all pediatric demographic and payer categories. Still, while a sizable proportion of children with epilepsy may be good candidates for surgery, far less than 1% receive surgery annually. Rates of epilepsy surgery remained significantly lower for black children and those on Medicaid indicating persisting disparity.

**Implications for Policy, Delivery, or Practice:** The rate of pediatric epilepsy surgery has increased indicating some increased awareness among health professionals of the benefits of early epilepsy surgery. However, surgery continues to be under-utilized especially among black children and those enrolled in Medicaid, indicating additional outreach efforts may be needed targeted toward general pediatricians, family medicine physicians, and general neurologists to improve referral of difficult to treat epilepsy cases to specialized care.

**Racial Variation in Heart Failure Comorbidities and Therapy Use in a Medicaid Population**

Fadia Shaya, University of Maryland School of Pharmacy; Ian Michael Breunig, University of Maryland School of Pharmacy; Mandeep R Mehra, Harvard Medical School; Center for Advanced Heart Disease, Brigham and Women's Hospital, Boston, MA

**Presenter:** Fadia Shaya, Ph.D., M.P.H., Professor; Director Of Research And Outreach

**Cips, CIPS:** Center for Innovative Pharmacy Solutions, University of Maryland School of Pharmacy, fshaya@rx.umaryland.edu

**Research Objective:** To explore the association between race, comorbidity, and first-line therapy use among patients with heart failure (HF) in a contemporary Medicaid population.

**Study Design:** Using medical/prescription/enrollment records from Maryland State Medicaid, we examine the prevalence of comorbidity and use prevalence of first-line therapies among white, black, Hispanic and other race/ethnicity enrollees diagnosed with HF. Diagnosis for HF was defined as the earliest encounter claim that included ICD-9 code 428.xx. Comorbidity diagnoses (chronic obstructive pulmonary disease (COPD), stroke, renal dysfunction, diabetes, psychological disorder, hyperlipidemia, chronic ischemic heart disease, hypertension, and other cardiovascular disease) were between patients’ earliest claim and within three months after HF diagnosis. First-line therapy use was ascertained using pharmacy claims with first-date-of-service between HF diagnosis and the end of follow up. Variation across race/ethnicity groups in comorbidities and therapy use is described.

**Population Studied:** Maryland State Medicaid, Managed Care Organization or Fee-for-services, non-dual enrolled, ages 18-64, with a diagnosis of HF between July 1st, 2005 and December 31st, 2009, and followed for at least 3 months.

**Principal Findings:** Among 15,764 HF patients, 60 percent (n=9,388) were black, 33 percent (n=5,158) white, 6 percent (n=919) other, 2 percent (n=299) Hispanic. Over half were female (55%percent); 29 percent were ages 18-44, 36 percent ages 45-54, and 36 percent ages 55-64. Prevalence (percent) of comorbidities in race/ethnicity groups was: COPD (40 white, 22 black, 20 other, 11 Hispanic; p<0.001), stroke (22 black/other, 20 white/Hispanic; p=0.170), renal dysfunction (38 Hispanic, 30 black, 27 other, 22 white; p<0.001), diabetes (42 white/Hispanic, 40 black, 38 other; p=0.040), psychological disorder (65 white, 52 black, 46 other, 37 Hispanic; p<0.001), hyperlipidemia (44 white, 39 Hispanic, 31 other, 33 black; p<0.001), chronic ischemic heart disease (47 white, 41 black/Hispanic/other; p<0.001), hypertension (76 black, 72 Hispanic, 68 white, 67 other; p<0.001), other cardiovascular disease (80 Hispanic, 79 black, 77 white/other; p=0.167). Excluding other cardiovascular disease, the median number of comorbid conditions was 3 in each race/ethnicity...
group. Among black, white, Hispanic and other race/ethnicity groups, only 5.8, 4.4, 9.0, and 7.3 percent had zero comorbidities, and 14.2, 11.4, 12.4, 15.8 percent had only one comorbidity, respectively. Hispanics (53 percent) were less likely than blacks (62 percent), whites (61 percent), or others (57 percent) to be prescribed ACE-inhibitor/ARB, beta-blockers, aldosterone antagonists, and/or other cardiovascular drugs including combination nitrates/hydralazine (p<0.001).

**Conclusions:** Among HF patients enrolled in Maryland Medicaid, whites were most likely to be diagnosed with COPD, psychological disorders, hyperlipidemia, and chronic ischemic heart disease. Hypertension was most likely among blacks, and renal dysfunction most likely among Hispanics. Multiple comorbidities are highly prevalent among all Medicaid enrollees with HF. Hispanics and other race/ethnicity were less likely to be prescribed or use therapies for HF compared to white and black HF patients.

**Implications for Policy, Delivery, or Practice:** This study is among the first to address the epidemiology of comorbidities in a high-risk Medicaid population, reflecting a demographic largely under-represented in large scale studies or clinical trials.

**Funding Source(s):** No Funding

**Poster Session and Number:** A, #114

**Comorbidity Burden among Heart Failure Patients in a Medicaid Population**

Fadia Shaya, University of Maryland School of Pharmacy; Ian Michael Breunig, University of Maryland School of Pharmacy; Mandeep R Mehra, Harvard Medical School; Center for Advanced Heart Disease, Brigham and Women's Hospital, Boston, MA

**Presenter:** Fadia Shaya, Ph.D., M.P.H., Professor; Director Of Research And Outreach Cips, CIPS: Center for Innovative Pharmacy Solutions, University of Maryland School of Pharmacy, fshaya@rx.umaryland.edu

**Research Objective:** Increasing prevalence of heart failure, increasing enrollment in state programs, sparse literature on population-based heart failure studies, and the associations between lower socioeconomic status, increased comorbidity burden and greater utilization rates necessitate an examination of the prevalence of HF comorbidity in a contemporary Medicaid population.

**Study Design:** Using medical/prescription/enrollment records from Maryland State Medicaid, we examine the prevalence of comorbidity and multiple-comorbidities among HF patients. Diagnosis for HF was defined as the earliest encounter claim that included ICD-9 code 428.xx. Comorbidity (chronic obstructive pulmonary disease (COPD), stroke, renal dysfunction, diabetes, psychological disorder, hyperlipidemia, chronic ischemic heart disease (CIHD), hypertension, and other cardiovascular disease (CVD)) was ascertained from ICD-9 codes observed between patients' earliest claim and within three months after HF diagnosis; psychological disorder was also determined using prescription records. The frequencies and cross-frequencies of the selected comorbidities are examined.

**Population Studied:** Maryland State Medicaid, Managed Care Organization or Fee-for-services, non-dual enrolled, ages 18-64, with a diagnosis of HF between July 1st, 2005 and December 31st, 2009, and followed for at least 3 months.

**Principal Findings:** Among 15,764 HF patients, 60 percent (n=9,388) were black, 33 percent (n=5,158) white, 6 percent (n=919) other, 2 percent (n=299) Hispanic. Over half were female (55 percent); 29 percent were ages 18-44, 36 percent ages 45-54, and 36 percent ages 55-64. The most common comorbidity was other CVD (78 percent), followed by hypertension (73 percent), psychological disorder (57 percent), CIHD (43 percent), diabetes (41 percent), hyperlipidemia (37 percent), COPD (28 percent), renal dysfunction (28 percent), and stroke (21 percent). This pattern persisted within any particular comorbidity sub-group. Excluding hypertension and other CVD: 10 percent of patients had zero comorbidities, 20 percent had only one, 70 percent had multiple comorbidities; 0.7 percent (n=114) had every comorbidity. The median number of comorbidities was 2; median being 4 if hypertension and other CVD are included.

**Conclusions:** An overwhelming majority of HF patients enrolled in Maryland Medicaid have multiple comorbidities. The prevalence of any comorbidity above was no less than 21%; the most prevalent comorbidities being hypertension, other cardiovascular disease, and psychological disorder.

**Implications for Policy, Delivery, or Practice:** Our findings call attention to the level comorbidity in a high-risk Medicaid population, reflecting a demographic largely under-represented in large scale studies or clinical
The Use of Transarterial Chemoembolization for Treating Hepatocellular Carcinoma in the SEER-Medicare Population

Ian Michael Breunig, University of Maryland School of Pharmacy; Fadia Shaya, University of Maryland School of Pharmacy; Fadia T Shaya, University of Maryland School of Pharmacy; Nader Hanna, University of Maryland School of Medicine; Brian Seal, Bayer HealthCare Pharmaceuticals, Inc.; Viktor Chirikov, University of Maryland School of Pharmacy; C. Daniel Mullins, University of Maryland School of Pharmacy

Research Objective: Transarterial chemoembolization (TACE) is a first-line therapy to treat intermediate staged hepatocellular carcinoma (HCC) and multiple courses of TACE are often undergone. TACE is often used as a bridge-therapy to surgery or to treat tumor recurrence, and TACE-Sorafenib combination therapy is a promising new therapeutic approach based on synergistic properties. We explore historical patterns of TACE use to inform future evaluations of the effectiveness of TACE as it is utilized in a transformative therapeutic landscape for HCC.

Study Design: Data are from the Surveillance, Epidemiology and End Results (SEER) and linked Medicare databases, with claims generated from Parts A and B. We describe rates of TACE use before and after transplant, resection, and ablation in the follow-up period. Among non-transplant/non-resection patients, we describe rates of multiple TACE treatments and use Kaplan-Meier analysis to examine mean weeks between HCC diagnosis, first TACE, repeated TACE, and death.

Principal Findings: There were 11,047 total HCC patients. Among 411 transplant patients, 29 percent received TACE before transplant, and 3 percent after transplant. Among 851 resection patients, 2 percent received TACE before resection, and 11 percent after resection. Among 1116 ablation patients, 17 percent received TACE before ablation, and 19 percent after ablation. Among 1228 non-transplant/non-resection patients who received TACE, 57 percent received one course, 24 percent received two courses, 11 percent received three courses, and 8 percent received 4 or more courses. Among patients with one, two, three, and four or more TACE treatments, first treatment was at 26, 21, 21, and 20 weeks after HCC diagnosis, and TACE was discontinued after 35, 53, 95, and 125 weeks, respectively; mean weeks survived post-discontinuation was 64, 61, 59, and 50 weeks, respectively.

Conclusions: When used with transplantation, TACE has been more often used as a bridge-therapy; with resection, more often to treat non-optimal tumor response. TACE is frequently used concomitantly with ablation. Intent to treat first-line TACE patients with multiple courses of TACE is difficult to ascertain in observational studies since additional treatments may be prescribed under a patient-specific treatment protocol or due to non-optimal tumor response. Nonetheless, mean weeks survived after discontinuing TACE was relatively similar regardless of number of treatments received.

Implications for Policy, Delivery, or Practice: The value of TACE, and related combination therapy, should be viewed with regard to its ability to extend the period of eligibility for treatments, reduce rates of recurrence, as well as extend overall survivorship.

The Effect of a Change in Out-of-Pocket Policy of the National Health Insurance on Medical Use in the Tertiary Hospitals

Changwoo Lee, Korea Insurance Research Institute; Euichul Shin, The Catholic University of Korea

Research Objective: This study explores whether the increase of outpatient service cost sharing rate at tertiary hospitals, enforced from July 2009, indeed decreased outpatient service...
utilization at tertiary hospitals. Using the Korea Medical Panel Survey(KMPS), we investigate if the tertiary hospital patient cost sharing policy change did not at all affect medical use in the tertiary hospital.

**Study Design:** Especially, private health insurance holders are likely to be less sensitive to change in NHIC’s cost sharing rate since their out-of-pocket payments for the large hospital are reimbursed through the private health insurance. Therefore, considering them as a control group, we attempt to determine the effect of the patient cost sharing policy change at large hospitals on the outpatient utilization at upper level hospital by the difference-in-difference method.

**Population Studied:** For this study 2009, KMPS data is used. Medical panel data enables independent estimation by constructing samples of 8,000 nationwide households, and it evaluates medical use and medical cost expenditures of 16 major cities (Jung, 2009). It contains detailed information, not only including individual’s socio-economical characteristics and also whether or not individual holds private medical insurance policy, and its coverage. Especially in health care use, there is a merit in that the date of health care use can be traced down, which allows to separate before and after the 2009 (patient cost sharing) policy change.

**Principal Findings:** When private health insurance holders are selected as a control group, the difference between the control group and treatment group existed. The results show that the change of cost sharing policy indeed is effective.

**Conclusions:** According to the data provided by Health Insurance Review & Assessment Service(HIRA), which only investigates general tendency of upper level hospital outpatient service use patients cost sharing policy change carried out in July 2009 may be determined to be not as effective. However, determining whether there was a policy change via difference-in-difference method, patient cost sharing policy indeed seems to be effective. If further data is offered for support, robustness of the result can be once confirmed.

**Implications for Policy, Delivery, or Practice:** The results show that the change of cost sharing policy could be effective in reducing medical use.

**Developing and Testing Pediatric Quality Indicators for Administrative Claims Data**

Emily Ehrlich, Truven Health Analytics; Mark W. Smith, Truven Health Analytics; Ginger Carls, Truven Health Analytics; Marilyn Novich, Truven Health Analytics

**Presenter:** Mark W. Smith, Ph.D., Director, Truven Health Analytics, mark.w.smith@truvenhealth.com

**Research Objective:** Administrative claims data remain the only widely and readily available source of information on processes and outcomes of care for children. Yet, few pediatric quality indicators have been developed that can be implemented with claims data alone. As a result little is known about the quality of care provided to children on a regional or national scale. Here we describe the process used to identify a large set of pediatric quality indicators for use with claims data and how they were tested for scientific acceptability.

**Study Design:** Project staff conducted a literature review of pediatric quality indicators. Draft definitions based on the literature review were edited by an expert panel of physicians. The final definitions were transformed into programming specifications and then applied to claims data form a Midwestern health plan. Corresponding patient medical record audits were conducted. The team assessed validity for a subset of the measures, comparing agreement between sources in eligibility for the measure (the denominator of a quality indicator rate) and in performance, or evidence that high-quality care was given as indicated (the numerator). Agreement was assessed through Cohen’s Kappa statistic and the Spearman correlation coefficient.

**Population Studied:** The quality measures apply to children ages 0-17 regardless of gender, race, or insurance status. Indicators were tested against medical records of children enrolled in a private health plan in the Midwest.

**Principal Findings:** The literature review revealed a dearth of quality measurement for children’s healthcare using administrative claims, but also a wealth of evidence-based practices that are observable in claims data. The project staff developed and the expert panel honed more than 80 candidate indicators for ambulatory screening, prevention, or treatment of high-volume and high-impact conditions. Twenty-eight of these indicators, spanning 12 conditions, were validated against medical
records. Of these, twenty-four had eligibility (denominator) agreement of 65% or greater, and 10 had 85% or greater agreement. Sixteen of the 28 indicators differed in their performance (numerator) by less than 20 percentage points. Ten indicators had a Cohen’s Kappa greater than 0.75, indicating a high level of agreement between administrative data and medical records. Correlations followed a similar pattern.

**Conclusions**: Published studies and clinical experience provide a strong foundation for potential pediatric quality indicators. This study provides initial evidence that many can be measured with reasonable reliability using claims data.

**Implications for Policy, Delivery, or Practice**: If further validation supports these measures, it will soon be possible to track the level and trends in the quality of children’s health care on a broad scale.

**Evaluating PROMIS Physical Function Measures in Older Adults at Risk for Cognitive Decline**

Kathleen Smyth, Case Western Reserve University; Curtis Tatsuoka, Ph.D., Case Western Reserve University; Nasim Seifi, M.A., Case Western Reserve University; Martha Sajatovic, M.D., Case Western Reserve University

**Presenter**: Kathleen Smyth, Ph.D., Associate Professor, Epidemiology and Biostatistics, Case Western Reserve University, kathleen.smyth@case.edu

**Research Objective**: Independence in activities of daily living (ADLs) becomes a central concern with age. Elders with mild cognitive impairment (MCI) have subtle functioning deficits that may predict conversion to dementia. With exponential population growth among U.S. elderly, there is a critical need for patient-reported measures that efficiently assess physical functioning in elders at risk for cognitive decline (CD). The Patient Reported Outcomes Measure Information System (PROMIS) aims to assess symptoms/problems across a wide array of chronic diseases and conditions. PROMIS has made significant strides, but assessing the performance of its measures in diverse populations and in comparison with commonly used (Legacy) measures is needed. Our goal was to evaluate the utility of a subset of PROMIS physical function items most likely to capture functional change related to CD.

**Study Design**: In a prospective cohort study, we administered PROMIS and Legacy measures of physical function, depression and cognition, and demographic, comorbidity and health literacy measures to older adults. Prior to assessment, an expert panel experienced in the care or study of elderly persons with cognitive impairment used the Nominal Group Process Method to select 62 items from the 125-item PROMIS physical functional battery deemed most likely to be affected by CD.

**Population Studied**: Over 300 individuals 70 or over were recruited from clinical and community settings. Three sub-groups were targeted: those with normal cognition, MCI and mild to moderate dementia. We report here on findings from baseline interviews with the first 180 subjects recruited.

**Principal Findings**: Total scores on the PROMIS items correlated in the expected direction with Legacy measures of: global basic and instrumental ADLs and an ADL measure designed for use in MCI (r = .31 to .65, p = .000). Significant correlations with both basic and instrumental ADL measures suggest that the PROMIS items capture multiple constructs (confirmed by factor analysis). In regression models predicting PROMIS and Legacy measures, level of cognitive impairment was an independent predictor only of the MCI-specific measure. Number of comorbidities (p = .009) and depressive symptoms (p = .000) were independently related to the PROMIS measures (but to only some of the Legacy measures) in the expected direction. Health literacy was not a significant predictor of any measure.

**Conclusions**: Findings suggest that a subset of PROMIS physical function items chosen for their relevance to CD span both basic and instrumental ADL domains as captured by global Legacy measures. Scores on both the PROMIS and Legacy measures appear sensitive to depression, possibly due to associated apathy and fatigue. The usefulness of PROMIS physical function items may be enhanced by developing sub-domain scores to capture the multidimensional nature of the items and increase sensitivity to CD.

**Implications for Policy, Delivery, or Practice**: Given the aging of the U.S. population, valid and reliable patient reported outcome measures for persons at risk for or experiencing CD are critical in clinical practice and research. Our initial evaluation of the PROMIS physical
function measures suggests that with additional work to uncover sub-domains, they may be useful in clinical practice with elderly populations and in assessing the effects of interventions in this group.

**State Regulation of Nonprofit Hospital Community Benefit**

Martha Somerville, The Hilltop Institute

**Presenter:** Martha Somerville, J.D., Director, Hospital Community Benefit Program, The Hilltop Institute, msomerville@hilltop.umbc.edu

**Research Objective:** The term, "hospital community benefits" refers to nonprofit hospitals' activities, including free and discounted care, reimbursement "shortfalls" from Medicaid participation, improving access to care, medical research, health professionals' training, and other contributions to promote population health. A hospital's community benefit activity may express its charitable mission, but it also serves to justify tax exemption. This study identifies varied approaches of and trends in state legislation and regulation governing nonprofit hospital community benefit responsibilities and hospitals’ accountability to the communities they serve.

**Study Design:** Collection and analyses of primary data from the statutes and regulations of the 50 states. Data collection determined the presence or absence in each state of law or regulation mirroring selected elements of the federal nonprofit hospital community benefit requirements established by the Affordable Care Act (ACA) §9007 (26 U.S.C. §501(r)). Relevant state law and regulatory activity were initially identified by law students. A nonscientific survey, primarily of state hospital association representatives, was conducted to support verification of researchers’ negative findings. Accuracy was confirmed by review and, as necessary, correction by J.D./MPH-credentialed program staff.

**Population Studied:** This study identifies and analyses state community benefit requirements and their relevance to nonprofit hospital accountability and transparency and, ultimately, to population health.

**Principal Findings:** Data collection has been completed, with ongoing analysis scheduled for completion no later than March 1, 2013. Principal findings will focus on the varied approaches to state community benefit regulation including requirements relating to: The provision and reporting of nonprofit hospital community benefits; Community health needs assessment; Charity care and financial assistance; Limitations on patient charges, billing, and debt collection; Community benefit as a condition of tax exemption and hospital licensing.

**Conclusions:** Before the ACA, nonprofit hospitals’ community benefit contributions sprang from the demands of charitable mission, loosely-defined federal tax exemption requirements, and a patchwork of varying state laws and regulations. Today, the ACA and IRS have standardized community benefit requirements, but only at the federal level. The financial value of state tax exemption is at least as great as that of the federal exemption and thus creates a powerful financial incentive for nonprofit hospital community health improvement activities. Analysis of the study’s findings will identify policy implications associated with differing state regulatory approaches, such as: Requiring nonprofit hospitals to provide and/or report community benefits at the state level; Specifying mandatory community benefit expenditure levels; Conditioning tax exemption, licensing, or other government action benefitting hospitals on the provision of community benefits.

**Implications for Policy, Delivery, or Practice:** The study’s findings will be useful to state legislators as they consider legislative, regulatory, and policy approaches that may either reconcile existing state community benefit policies with the new federal requirements; retain state regulatory frameworks in their current form, or establish new, independent state standards that may build on or exceed federal community benefit requirements.

**Improving Depression Care through an Online Learning Collaborative**

Melissa Starkey, American College of Physicians; Amir Qaseem, American College of Physicians

**Presenter:** Melissa Starkey, PhD, Clinical Associate, Clinical Policy, American College of Physicians, mstarkey@acponline.org
**Research Objective:** To develop and study the impact of an electronic educational module for physicians and practice teams to improve the screening, diagnosis and management of depression

**Study Design:** The study had a pre-post design. The intervention consisted of an online educational program and conference calls with the practices to aid physicians and their teams in goal setting and to help them with the development and implementation of a quality improvement strategy. Data for this study were gathered from: 1) physician practice pattern surveys and 2) chart abstractions. The Likert-scale survey was intended to capture what the physicians believed they were doing, while the chart audit tool assessed what the physicians were actually doing. Baseline measurements were taken at the initiation of the study, and the follow-up measurements were taken after completion of the intervention.

**Population Studied:** Internal medicine physicians managing patients with depression

**Principal Findings:** Both chart abstraction and survey data indicated that participation in the educational intervention helped physicians to successfully incorporate use of the Patient Health Questionnaire-9 (PHQ-9) into their practices. Data from chart abstractions showed that the PHQ-9 was used to detect and/or diagnose depression for 60.8% of patients post-intervention compared to 17.6% at baseline. Physicians also self-reported administering the PHQ-9 to assess initial treatment response at follow up more often after completing the intervention than at baseline. Additionally, more practices self-reported repeating a depression evaluation (such as the PHQ-9) over time during treatment in order to gauge success of treatment with antidepressants or counseling. There were also improvements in screening of suicide, alcohol and substance abuse following the educational intervention. Other practice changes evidenced from the chart abstractions included an increase in the percentage of patients who were assigned depression care managers (from 3.9% to 20.2%) as well as increased entry of patients into depression registries (7.6% compared to 24.3%).

**Conclusions:** The educational program was helpful for eliciting practice change and physicians successfully incorporated depression screeners into their practices. They noted that having a way to quantify depression severity was previously unknown to them prior to the project and helped them in managing their patients’ conditions. However, physicians were unsure about how to set practice improvement goals and needed an appreciable amount of coaching during conference calls.

**Implications for Policy, Delivery, or Practice:** Promoting the uptake of depression screening tools such as the PHQ-9 can be instrumental in effecting positive practice change. Many practices reported that these screeners were relatively easy to use and incorporate as routine screening tools in their practices. A big challenge to overall quality improvement for depression management was a lack of resources as well as getting “buy in” from other physicians in the practice and from administration.

**Development of Patient Experience Survey Tool in Singapore: Use of Cognitive Testing**

**Presenter:** Lindy Tan, Biostatistician, College of Medicine Building, Ministry of Health, lindy_tan@moh.gov.sg

**Research Objective:** With an ageing population and increase in chronic disease burden in Singapore, various national initiatives are put in place to facilitate integrated care for patients, between acute and community settings. Assessing patient experience as they navigate the healthcare system is one way to assess the effectiveness of such measures. A national patient experience survey (NPES) was proposed to provide a standardized methodology for collecting and reporting information through a reliable set of questions that would capture the patients’ experiences in local hospitals.

**Study Design:** The HCAHPS (Hospital Consumer Assessment of Healthcare Providers and Systems) survey is a national, standardised, publicly reported survey of patients’ perspectives of hospital care in the US. It allows objective and meaningful comparisons to be made across hospitals on a national basis. To assess if this is a suitable tool for use in the local context, among the major ethnic groups (Chinese, Malays, Indians) in Singapore, cognitive testing was conducted on 6 selected items from HCAHPS. Items were selected based on...
potential for misunderstanding due to cultural context.
There were 2 rounds of cognitive testing conducted through the telephone. In round 1, English (N = 108) and Chinese (N = 36) cognitive testing took place concurrently. In round 2, survey items were translated into Melayu Behasa and cognitive testing was conducted on the selected items (N = 36). For English cognitive testing, participants were stratified by gender, ethnicity (Chinese, Malay, Indian), age (18 - 40, 41 - 65, > 65) and education (PSLE or less, secondary education, tertiary education) to represent the different gender, ethnic, age and education groups. For Chinese and Melayu Behasa cognitive testing, participants were also stratified similarly by gender, age and education.

**Population Studied:** Chinese, Malay and Indian Singapore residents/ permanent residents aged 18 years and above.

**Principal Findings:** Cognitive testing suggested that patients define "courtesy and respect", as well as "careful listening" similarly. Expectations include making the effort to communicate with patient such that the patient understands his/her condition and progress. This includes speaking in patient’s dialect and utilizing alternative ways of communication (e.g., drawing). Participants interpreted certain terms in varied ways. For instance, “discharge planning” was understood by several participants as a passive activity, such as whether the patient was informed of suitability of discharge and keeping the patient updated on his/her condition. Some items also captured unintended information. For instance, probing on responses to the item “During this hospital stay, how often did doctors explain things in a way you could understand?” showed that some participants did not understand things because they were in pain, dizzy or otherwise unable to focus on what the doctors were saying.

**Conclusions:** Cognitive testing gave a better understanding of patients’ expectations of the healthcare experience. It also revealed the need for clarification of terms used in the NPES.

**Implications for Policy, Delivery, or Practice:** It is necessary to directly survey patients to determine if their experiences have been hassle free. Survey items that are understood as intended and interpreted consistently across participants facilitate accurate measurement of our success with developing integrated care and patient-centeredness.

**Funding Source(s):** Other, MOH, Singapore

### Poster Session and Number: A, #123

**Trends in Breast and Cervical Cancer Screening Rates in the NBCCEDP – 1997-2009**

Florence Tangka, Centers for Disease Control; Tamara Lee, U.S. Census Bureau; Jerzy Wieczorek, U.S. Census Bureau; Wesley Basel, U.S. Census Bureau; Kristy Joseph, Centers for Disease Control; Janet Royalty, Centers for Disease Control

**Research Objective:** Breast and cervical cancer screening rates are low among low income women who lack insurance coverage for mammography and Pap tests. To help these underserved women gain access to breast and cervical cancer screening services, the U.S. Congress passed the Breast and Cervical Cancer Mortality Prevention Act of 1990 (Public Law 101-354), authorizing the Centers for Disease Control and Prevention (CDC) to establish the National Breast and Cervical Cancer Early Detection Program (NBCCEDP) referred to henceforth as the Program. The Program provides services through cooperative agreements, which are in place in all 50 states, the District of Columbia (DC), 5 U.S. territories, and 12 tribes. To date, no study has been done to examine the trends in mammography and Pap tests use in the NBCCEDP.

We examines the trends in breast and cervical cancer screening in the NBCCEDP, to find out if screening rates have changed from 1997 through 2009.

**Study Design:** We analyzed data from the US Census Bureau and the Program from 1997 through 2009 to describe the trends in breast and cervical cancer screening rates in the NBCCEDP, by age groups and by race/ethnicity. Low-income, uninsured women aged 18-64 are eligible for free breast and cervical cancer screening services through the Program. We used data from the U.S. Census Bureau to estimate the number of women eligible for the program, based on insurance status and income. The estimates were adjusted for hysterectomy status using the National Health Interview Survey. We obtained the number of women receiving Program-funded Mammograms and Pap tests from the Program.
Population Studied: Low-income, uninsured women aged 18-64 are eligible for free breast and cervical cancer screening services.

Principal Findings: Results: Rates of breast and cervical cancer screening test use by the NBCCEDP eligible population increased moderately (by less than 5%) over a decade. Screening rate increases varied by age-groups, and by race/ethnicity.

Conclusions: Reducing mortality and late-stage breast and cervical cancers are top priorities in public health. High screening rates results in a decrease in cancer incidence and mortality. Also screening identifies cancers at an earlier stage when treatment is possible and affordable. The NBCCEDP-eligible (underserved) population would benefit from additional interventions (patient navigators, access to usual source of care), besides paying for tests, that will increase their screening rates. Constant monitoring of breast and cervical screening rates trends is critical.

Implications for Policy, Delivery, or Practice: The next step would be to identify factors that explain the variation in screening rates and identify changes that CDC can implement to increase the average screening penetration rates. Such changes would help the program reach more disadvantaged women and help reduce disparities.

The Impact of a School-Community Integrated Behavioral Health Service on Child and Family Outcomes
Lauren Terhorst, Community Care Behavioral Health Organization; James Schuster, UPMC Center for High-Value Health Care, Community Care Behavioral Health; Shari L. Hutchison, MS, Community Care Behavioral Health Organization; Jane N. Kogan, PhD, UPMC Center for High-Value Health Care; Judith W. Dogin, MD, Community Care Behavioral Health Organization

Presenter: Lauren Terhorst, Ph.D., Clinical Outcomes Analyst, Community Care Behavioral Health Organization, terhorstl@ccbh.com

Research Objective: There is increasing concern about children’s unmet mental health needs, with many stakeholders interested in improving the integration of services between community mental health providers and schools. Working closely with several school districts in Pennsylvania to identify needed services and supports, provider organizations and a large nonprofit Medicaid managed behavioral health organization developed an integrated school based behavioral health (SBBH) Team Service to deliver care to youth and families through a clinical home model in schools. This study represents an evaluation of the impact of the implementation of SBBH Team Service on child and family functioning.

Study Design: Child and family functioning and therapeutic alliance were assessed by the Child Outcomes Survey (COS), an 11-item measure completed monthly by parents that assesses the child’s progress in treatment on key domains and facilitates family/Team communication about the child’s progress in treatment. Children’s symptoms and behaviors were assessed quarterly using parent and teacher completed Strengths and Difficulties Questionnaires (SDQ). Linear mixed models were utilized to examine changes over time in child functioning, family functioning, and behaviors during participation in SBBH services.

Population Studied: We identified 925 children receiving SBBH services; the mean age was 10 years with 77% boys. Children being served are racially and ethnically diverse with 28% Hispanic, 15% African American, and 9% more than one race.

Principal Findings: Over the first 12 months of SBBH services, results from the COS demonstrate a significant improvement in average levels of family functioning (F4, 2283=18.95, p<.001), child functioning (F4, 2196=46.36, p<.001) and therapeutic alliance (F4, 2169=6.28, p<.001). Greatest improvements in functioning occurred during the first 6 months, while the greatest improvement in therapeutic alliance occurred between 9 and 12 months. Parents report slightly higher levels of child difficulties but also higher levels of positive social behaviors on the SDQ compared to teacher report. Both parent and teacher report on the SDQ of the child’s total difficulties subscore shows significant improvement over time (F4,1380=13.84, p<.001 and F4,1034=15.27, p<.001, respectively). Parents report the most improvement in child difficulties within the first 3 months, while teachers report greatest improvement over the first 9 months. Parents and teachers also report a significant improvement in social behaviors over time (F4,1487=3.82, p=.004 and F4,984=7.09, p<.001). Parents report the most improvement in...
The Use of Patient Reported Outcomes in Managing Patients with Chronic Conditions: Experience From the Field

Debra Scammon, PhD, University of Utah, David Eccles School of Business; Andrada Tomoaia-Cotisel, University of Utah; Jennifer Tabler, BS, University of Utah, Department of Sociology; Lisa Gren, PhD, University of Utah, School of Medicine, Department of Family & Preventive Medicine; Julie Day, MD, Community Clinics, University of Utah Hospitals and Clinics; Michael K. Magill, MD, University of Utah, School of Medicine, Department of Family & Preventive Medicine

Presenter: Andrada Tomoaia-Cotisel, MHA, MPH, Research Associate, Department of Family & Preventive Medicine, University of Utah, andradat@hsc.utah.edu

Research Objective: To document our experience with (1) developing the capabilities to capture and use patient reported outcomes (PRO), and (2) collecting PRO over time. PRO are a source of useful data for delivering personalized healthcare. They can facilitate goal-setting and monitoring, as well as inform strategies to enhance patient engagement.

Study Design: A mixed methods design to examine experience in a care management program in which care managers (CM) are embedded into care teams. In a pilot study, during initial care management visits, patients completed several assessments with data entered into their Electronic Medical Record (EMR): (1) the PHQ-9 depression screen, (2) the Patient Activation Measure (PAM), and (3) the RAND 36 perceived quality of life measure. Regular CM meetings were held to discuss implementation issues, including those related to the collection and use of PRO. Solutions have been evaluated in Plan Do Study Act cycles. Changes in patients’ assessment results were assessed using test-retest t-tests (alpha =0.05).

Population Studied: Patients with chronic conditions participating in the care management program within nine University Health Care Community Clinics (UUCC), with at least one CM visit during the last 18 months.

Principal Findings: Challenges in developing the capacity to collect and use PRO include developing: (1) infrastructure and capability to capture and integrate PRO into the EMR; (2) work flows and processes to administer assessments; and (3) reporting capabilities so that care managers (CM) can access, interpret, and use the PRO. Attempted administration of repeated assessments revealed several realities: (1) Although 980 patients participating in our care management program, less than 400 have completed each of our assessments at least once (PAM – 390; PHQ9 – 391; RAND 36 -372) and only 7-8% have completed these assessments multiple times. However, when assessments are administered at initial CM visits, the opportunity to obtain re-assessments is increased. (2) Change in the desired direction is evident and statistically significant (p<.05) for some measures among patients who have completed assessments multiple times. Improvement on General Health, Social Functioning, and Energy/Fatigue was significant as measured by the RAND 36; the PAM Activation score showed statistically significant improvement; and the Severity and Symptom scores on the PHQ9 improved significantly. (3) PRO provide important feedback for patients regarding their progress. A patient recently diagnosed with diabetes with an initial depression score of 14 (PHQ9) expressed concerns about weight and needed lifestyle changes. With frequent CM visits to discuss diabetes, diet, and exercise, and motivational interviewing about self-control, the patient's PAM activation score increased by 11 points, his RAND General Health score improved by 50 points and his PHQ9 decreased by 14 points.
Conclusions: PRO complement clinical information for the management of patients with chronic conditions. PRO are challenging to systematically collect, but they provide important feedback for CMs to help patients reach their personal goals.

Implications for Policy, Delivery, or Practice: Building capacity to collect and use PRO is challenging but benefits to patients are observed. Thus, incentives for primary care practices to implement protocols for the ongoing collection of PRO should be encouraged. EMRs provide important infrastructure for acquiring PRO.

Characterization and Feasibility of a Care Manager-Based Transitions Management Program within a Patient Centered Medical Home
Timothy W. Farrell, MD, University of Utah Department of Family & Preventive Medicine; Andrada Tomoia-Cotisel, University of Utah School of Medicine; Kimberly Brunisholz, MST, University of Utah Department of Family & Preventive Medicine; Norman Waltzman, PhD, University of Utah Department of Economics; Karen Gunning, PharmD, University of Utah Department of Pharmacotherapy; Andrade Tomoia-Cotisel, MPH, MHA, University of Utah Department of Family & Preventive Medicine; Debra Scammon, PhD, University of Utah Department of Marketing; Amber Ferdig, University of Utah Department of Family & Preventive Medicine; Michael K. Magill, MD, University of Utah Department of Family & Preventive Medicine

Presenter: Andrada Tomoia-Cotisel, MPH, MHA, Research Associate, Department of Family & Preventive Medicine, University of Utah School of Medicine, andradat@gmail.com

Research Objective: Care transitions programs supporting patients during the vulnerable period between hospital discharge and the first post-hospitalization outpatient visit often involve a transitions coach. Such support has had a variable effect on reducing readmissions, depending on context and level of support. Few care transitions programs to date explicitly embed the transitions coach function within the Patient Centered Medical Home (PCMH). The objectives of this study were to: (1) characterize care transitions occurring within a defined primary care population; and (2) determine the intensity of care manager (CM) effort required within a dedicated transitions management (TM) program involving CMs embedded within Care By Design, the University of Utah Community Clinics’ (UUCC) version of the PCMH.

Study Design: CMs deployed in 9 of 10 UUCCs identified UUCC patients discharged from the University of Utah Hospital based on a daily electronic registry. CMs logged each care transition from this electronic registry and, for patients they deemed to be at high risk of returning to the hospital or emergency department (ED), attempted a phone contact to the recently discharged patient or her caregiver using best practices in post-hospitalization transitional care. CMs conducted TM in addition to other care management duties targeted for patients with specific chronic conditions.

Population Studied: CM logs (N=2321) documenting review of UUCC patients transitioning from the ED to home or hospital to home between September 2011 and June 2012 were examined. The mean and median age of the transitioning patients was 49.1 and 48.8 years, respectively (SD 19.5). 569 (23.2%) of CM logs involved patients older than age 65.

Principal Findings: 1202 (51.8%) of CM logs documented transitions from the ED to home and 1119 (48.2%) of CM logs documented transitions from the hospital to home. 1459 or 57.1% of all transitions resulted in a CM phone contact to patients or their caregivers based on perceived risk of rehospitalization or return to the ED. Among these 1459 transitions, CMs successfully made phone contacts for 863 transitions (59.2%). Overall, 33.8% of discharges from the ED and hospital resulted in successful CM phone contact. The average CM workload was 38.6 transitions per month, or 1.29 transitions per day. Additional results will be presented comparing the hospital readmission and ED return rates of UUCC Medicare beneficiaries receiving TM to the overall Medicare population in Utah.

Conclusions: The majority of CM contacts within a PCMH-based transitions management program involved discharges from the ED. CMs judged 1 out of 3 of all care transitions to represent high risk of hospital readmission or return to the ED. The workload per CM required to execute TM after reviewing the daily electronic registry was about 1 transition per day.

Implications for Policy, Delivery, or Practice: While care transitions programs often focus on
hospital discharges in order to reduce hospital readmissions, we found ED discharges to be more numerous within a primary care population, suggesting that care transitions programs should incorporate both ED and hospital discharges. The TM program within the UUCC addresses both ED and hospital discharges. TM may be realistically incorporated within the care management function of the PCMH.

**Funding Source(s):** AHRQ

**Poster Session and Number:** A, #127

---

Debra Tan, MPH, University of North Texas Health Science Center; Rebecca Trocki, Agency for Healthcare Research and Quality; Shyam Misra, MD, PhD, Agency for Healthcare Research and Quality; Kishena Wadhwani, PhD, MPH, Agency for Healthcare Research and Quality; Francis Chesley, Agency for Healthcare Research and Quality

**Research Objective:** The purpose of this study was to determine research productivity: return investment in AHRQ funded research grants and to perform an analysis of the publication outputs and journal impact factors associated with AHRQ grants in the form of dissemination.

**Study Design:** AHRQ Grants On-Line Database (GOLD) was searched for grants funded from 2003-2010 to allow a two year lag time to publication for a new grant. The National Health Institute Query View and Report Database (NIH QVR) was subsequently searched based on principal investigator and grant identification number to determine any publications and journal impact factors. Findings were stratified based on AHRQ’s Portfolios of Research Priorities. Grant identification number, principal investigator, grant title, institution, state, project start date, project end date, portfolio, publication year, impact score, publication journal, author succession, investigator type and award amount were recorded

**Population Studied:** The Agency for Healthcare Research and Quality (AHRQ) invests in extramural research grants to improve the overall quality, safety, efficiency and effectiveness of health care for all Americans. The results of these extramural research grants in turn help Americans make better informed health care decisions to improve the quality of their health care services. Extramural research grants are prioritized into AHRQ’s Portfolios of Research: Comparative Effectiveness, Value, Health Information Technology, Prevention/Care Management, Patient Safety and Innovations/Emerging Issues.

**Principal Findings:** Overall journal impact score of AHRQ Portfolios of Research (2.034) was consistent with those for Health Services Research (2.293), the official journal of AcademyHealth which AHRQ funds. Health Information Technology received a large amount of funding (n=163, 48.98% of total budget) and had the second to highest average impact score (2.116). Prevention/Care Management received the highest average impact score (2.553) and the second to highest average publications (1.471) for grants. Patient Safety had the highest average publications (1.497). for grants Comparative Effectiveness had very few funded grants (n=20, 1.30% of the total budget) yet consistent average impact score (1.797) but fewer publications (0.80). Additionally, there was a total of 43 funded grants regarding health disparities. However, the number of total publications in peer reviewed journals and the total number impact scores remains consistent with AHRQ Portfolios of Research Priorities grants. The average journal impact score is relatively consistent with AHRQ’s Portfolios of Research Priorities (2.073). The average publication per one grant for AHRQ Health Disparities grants is manifold greater (4.372), however.

**Conclusions:** In summary, this study provides a comprehensive overview of the impact of AHRQ Funded Grants in terms of delivery of scientific knowledge to Health Services Research community. Overall Journal impact score of AHRQ Portfolios of Research (2.034) was consistent with Health Services Research journal impact score (2.293), which is the official journal of AcademyHealth. Although only 43 research projects addressing health disparities were funded by AHRQ, the average number of publications per grant was 4.372 and the average journal impact factor was 2.073, indicating that these funded projects have had significant contribution regarding scientific knowledge on health disparities to HSR community. Questions to be addressed in the future are whether funding has changed for...
Comparative Effectiveness since the implementation of the American Recovery and Reinvestment Act (ARRA).

**Implications for Policy, Delivery, or Practice:**
The outcome and results of the ARRA policy change have yet to be assessed. Moreover, further analysis should be done to examine how the Patient-Centered Outcomes Research Institute (PCORI) will affect the future of AHRQ's Comparative Effectiveness Portfolio funding.

Prospective analysis can be done using funding data obtained from this study. This may lead to a variety of detailed input-output analyses for AHRQ Portfolios of Research Priorities. For example, time histories showing funding or grant type, grants by institution, region, principal investigator, study design etc. could be constructed.

**Funding Source(s):** No Funding

**Poster Session and Number:** A, #128

**Analysis of Impact Scores Obtained as a Function of Review Cycles (From June 2010 To June 2012 Review Cycles)**
Debra Tan, MPH, University of North Texas Health Science Center; Rebecca Trocki, Agency for Healthcare Research and Quality; Shyam Misra, MD, PHD, Agency for Healthcare Research and Quality; Kishena Wadhwani, PhD, MPH, Agency for Healthcare Research and Quality; Francis Chesley, MD, Agency for Healthcare Research and Quality

**Presenter:** Rebecca Trocki, MSHAI, Program Analyst, Office of Extramural Research, Education, and Priority Populations, Agency for Healthcare Research and Quality, rebecca.trocki@ahrq.hhs.gov

**Research Objective:** To examine the trend of scientific quality of research grant applications submitted to AHRQ with time, we assessed the overall impact scores provided by each of 5 standing study sections as a function of times during the past 7 review cycles (from June 2010 to June 2012).

**Study Design:** As at the NIH, the Scientific Peer Review Committees at AHRQ use 9 points overall impact score system to evaluate the scientific merit of research grant applications submitted to AHRQ for funding opportunity. This analysis is based upon the enhanced score criterion http://grants.nih.gov/grants/guide/notice-files/NOT-HS-10-002.html using the final impact scores assigned to the applications that were discussed at the review meetings from five study sections and Special Emphasis Panel (SEP) that were reviewed from June 2010 to June 2012 (a total of 7 review cycles). The data used in this analysis was from the National Institutes of Health (NIH) Query View & Report Database (QVR system). Microsoft Excel and SPSS were the tools used for analysis.

**Population Studied:** Research grant applications submitted to AHRQ were reviewed by one of the 5 standing study section committees or by the Special Emphasis Panel (SEP), depending whether these applications responding to Program Announcement (PA) or Requests for Application (RFA) http://www.ahrq.gov/fund/grantix.htm#PA for FY2010 – FY2012. The 5 study section review committees at AHRQ are: Healthcare Systems & Value Research (HSVR) Healthcare Information Technology Research (HITR) Healthcare Effectiveness and Outcomes Research (HEOR) Healthcare Safety and Quality Improvement Research (HSQR) Healthcare Research Training (HCRT), which are described in detailed under the weblink: http://www.ahrq.gov/fund/peerrev/peerdesc.htm. In addition to the 5 study section review committees, AHRQ also has convened many SEPs to evaluate grant applications responding to the RFAs.

**Principal Findings:** The means impact scores trend to increase with time in terms of review cycles (from June 2010 to June 2012). The means impact scores trend to increase with time in terms of review cycles (from June 2010 to June 2012). For example, for the HCRT, HQER or HSR study section, the means impact scores decrease to a lowest values of about 31-35 the exception of February 2011 review cycle meeting. The means of overall impact scores gradually increased to higher values at the subsequent review cycles to about 38 to 53 for all 5 study sections. The means for the June 2010 cycle ranged from 36.26 – 40.76 and the means rose to upward trend for the June 2012 cycle at 38.48 - 53.46 range showing an upward trend. Although the mean values of impact scores implicated an upward trend from June 2010 to June 2012, there was no statistical significance among these mean values (P value greater than .05).

**Conclusions:** Our analysis of impact scores among study sections as a function of time reviewed no statistically significant differences, indicating that the AHRQ peer review process is...
consistent in terms of quality of the scientific review among study sections.

**Implications for Policy, Delivery, or Practice:**
Our findings could provide useful information to the AHRQ leadership as well as extramural health services research community regarding the scientific peer process for grant applications submitted to AHRQ for funding opportunity.

**Funding Source(s):** No Funding

**The Study of the Relationship between Knowledge, Attitude and Practice toward the Acceptance of H1N1-New Flu Vaccine among Professionally Active Nurses in Taiwan**

Bin-Guang Su, Fooyin University, Department of Health-Business Administration, School of Nursing; Kai-Li Tsai, Texas Woman's University; Ni Chen, Fooyin University, Department of Health-Business Administration, School of Nursing; Shu-Hsing Yeh, Fooyin University, Leisure and Recreation Industry Department, College of Humanities and Management; Cheng Yu Ling, Fooyin University, Department of Health-Business Administration, School of Nursing; Yi-Xiu Zheng, Kaohsiung city Government, Nursing Department of Management, School of Nursing; Lin yeng ling, Fooyin university hospital, EEG examination room; Yu ping Chen, Fooyin University, Department of Health-Business Administration, School of Nursing

**Research Objective:** Along with the development and promotion of public health effort, the main killer diseases have been changing from acute infectious diseases to chronic ones throughout the past decades. Unfortunately, some highly contagious infectious diseases still caused a great number of deaths lately and it raised great concerns about the control of outbreak as well as the prevention of the newly evolved infectious diseases, such as SARS or Swine Flu. This study is to explore and discuss the relationship between nursing staffs’ knowledge, attitude and their actual practice toward receiving the vaccine for H1N1 swine flu. The purposes of this study include: 1) Assess the accuracy of care knowledge for H1N1-swine flu patients among professionally active nurses. 2) Examine the factors affecting the willingness in receiving H1N1 vaccine among professionally active nurses.

**Study Design:** This study is designed to explore and examine the relationship between the perceptions (knowledge and attitude) of the H1N1-New Flu and their practice in accepting vaccination among clinical nurses in Taiwan. The study performs a survey to collect information from professionally active nurses of their personal characteristics and assessments of their knowledge, attitude and practice in vaccine after the national vaccine campaign period. Based on this data, we further analyze to examine the difference and relationship between the knowledge, attitude and practice toward the H1N1-New Flu and its vaccine acceptance among professionally active nurses. Using the linear and logistic regressions, this study examines the impacts of personal characteristics on vaccine acceptance behavior. This study further uses a path analysis to examine if education level will affect the knowledge level and further influence the willingness to accept vaccine.

**Population Studied:** The subjects of this study include all professionally active nurses working at health stations, hospitals above the district-hospital level, clinical nurses at school in Pingtung County, Taiwan. Altogether, four hundred and ninety-four effective sample surveys were collected. The surveys toward all nurses working at health stations in this county were delivered and collected either in person or through mails. For those surveys performed toward nurses working at hospitals, it is conducted and collected through a random sampling procedure. We first sample hospitals randomly to get a list of participating organizations, then sent out the official written request to get approvals for the survey to be performed at their hospitals. With the approvals from hospitals, we sent out invitation letters to all nursing staffs at hospitals according to the licenses registration record at the county health department to inquire their intentions to participate in the study. The aim was set to reach more than thirty percent of full time employees at each health institutions to be our sample subjects. The sampling procedure and surveys were conducted and collected during February to April 2010 based on the following inclusion criteria:

1) Must be clinically practice or prevention focus practice registered nurse (RN) or license-practice nurses (LPN)
2) Must practice nursing in Pingtung County, Taiwan
3) Must be younger
than sixty years of age who can clearly read and comprehend the contents of the survey and willing to participate in the study.

Principal Findings: This study finds that fewer than half of the professionally active nurses receive influenza vaccination every year. Even with the raging H1N1-New Flu in the end of 2009, it did not increase the acceptance rate of the H1N1 vaccination much (64.57%). This study also finds that professionally active nurses with graduate level of education score significantly higher in the knowledge test about the H1N1-New Flu and its vaccine than those from other groups with lower education levels. Through linear regression analyses, significant differences in score of knowledge test are also found among different working institutions. However, no significant difference was found among other factors, such as, age, frequency of influenza infection, having chronic diseases, side effects due to the vaccination, or even willing to pay for family to receive vaccination using self-pay. The results from a path analysis also show no significant difference if education level acts as the factor influencing the vaccination acceptance practice behavior directly. However, there is a significant association between the education and vaccination acceptance behavior if the score from knowledge test about H1N1 plays as the intervening factor which receives the impact from education level then further transfers it to influence the vaccine acceptance behavior. The results show that education level alone is not the influential factor affecting the willingness of vaccine acceptance. However, acting as an intervening variable, education level may help improve the knowledge scores and further influence the willingness of vaccination acceptance.

Conclusions: This study finds that improving the knowledge and attitude toward the H1N1 vaccine among professionally active nurses actually has significant impacts on vaccine acceptance behavior and it further plays a role in improving the vaccination rate. It is suggested that the CDC in Taiwan should provide sufficient educational material to promote the safety of the H1N1 vaccine in the campaign. In addition, this study also finds it helpful if hospitals of all levels and health departments not only systematically report the adverse reactions due to the vaccine injection but also propose effective prevention mechanisms to them. Since H1N1 is different from and more fatal than the general influenza and H1N5 (bird flu); CDC in Taiwan needs to promote the epidemiologic concept of disease prevention in their operation, as well as, encourage professionally active nurses and other health workers to participate more in those activities advocating disease prevention and absorb right information.

Implications for Policy, Delivery, or Practice: The final knowledge test score in this study was surprisingly low among the nearly five hundred participating professionally active nurses. It may imply an opportunity to enhance the on the job training for those professionally active nurses who provide the primary level of patient care. In addition, professionally active nurses working at hospital ICUs, ERs, dialysis centers, nursing administration or infection control departments scored higher than those who work at health stations or schools may imply that the government needs to put more effort on providing adequate information to those remote areas. In general, professionally active nurses working as the front line health practitioners who expose directly to the diseases, bacteria and virus, should have the highest priority to receive the vaccination. This study finds that there are about 10.37% of professionally active nurses who never received government provided influenza vaccination and only 42.11% received it every year. A mandatory or financially incentive vaccination policy may be suggested to protect these front line workers. Finally, another important finding is that education level among professionally active nurses affects the knowledge of the disease, and the knowledge level. It further influences the vaccine acceptance behavior. It implies that to promote the acceptance rate of vaccination should start with improving the perception, including knowledge and attitude, of the H1N1-New Flu and its vaccine.

Smoking and Adult Asthma Outcomes in the United States, 2006-2009
Jamie S. Huang, MPH, University Of Texas School Of Public Health; Chu-lin Tsai, University of Texas School of Public Health; Ching-Yi Chuo, MSPH, University Of Texas School Of Public Health; Chu-Lin Tsai, MD, ScD, University Of Texas School Of Public Health

Presenter: Chu-lin Tsai, M.D., Sc.D., Assistant Professor Of Epidemiology, Epidemiology, University of Texas School of Public Health, chu-lin.tsai@uth.tmc.edu
Research Objective: Little is known about the effect of smoking on asthma outcomes in adults, particularly at a national level. The objective of this study was to investigate the impact of smoking on asthma outcomes (asthma control, health care utilization and cost, and quality of life).

Study Design: We combined data from multiple panels of the Medical Expenditure Panel Survey (MEPS) to form a longitudinal cohort from 2006 to 2009. The MEPS is a nationally representative survey of the US noninstitutionalized individuals and their medical providers and employers. Participants are interviewed in person for 5 rounds over 2 full calendar years. Individuals provide information on their demographic and socioeconomic characteristics, insurance, medical conditions, health care and medication use, and health status. The Medical Provider Component of the survey is used primarily to supplement individual-reported expenditure information.

Population Studied: Individuals aged 18 to 45 years with current asthma at baseline were identified as study subjects for the present analysis. Based on self-reported smoking status, subjects were divided into two groups: current smokers and non-current smokers. Baseline demographics were compared between the two groups, and smoking status at baseline was used to predict asthma outcomes in subsequent years.

Principal Findings: After the weighting procedures, 30% of adults with asthma in the US reported current smoking. There were an estimated 6,008,000 smoking and 14,000,000 nonsmoking asthmatics in the US. Compared with nonsmoking asthmatics, smoking asthmatics were more likely to be non-Hispanic white (70% vs. 64%, p=0.02), uninsured (28% vs. 9%, p<0.001) or on Medicaid (28% vs. 13%, p<0.001), poor (30% vs. 13%, p<0.001), and less educated (12 vs. 14 years, p<0.001). Smoking asthmatics were more likely to have hypertension (27% vs. 19%, p=0.046), emphysema (5% vs. 1%, p=0.01), chronic bronchitis (21% vs. 9%, p<0.001), and to report poor health status (10% vs. 5%, p<0.001). For asthma outcomes in the subsequent years, smoking asthmatics were less likely to use preventive asthma medicine (34% vs. 42%, p=0.049), visited office-based providers less (5.2 vs. 7.4 times a year, p=0.01), and had lower annual total health expenditure ($3,774 vs. $4,690, p=0.03), compared with nonsmoking asthmatics. Finally, smoking asthmatics reported worse quality of life with lower SF-12 mental health scores (45 vs. 49, p<0.001) and physical health scores (46 vs. 50, p<0.001), compared with nonsmoking asthmatics. After adjusting for baseline characterizes and disease severity, these many differences in asthma outcomes persisted, except that the difference in health expenditure was explained by insurance and disease severity.

Conclusions: Despite having a chronic respiratory disease, about one third of asthmatics still smoke cigarettes. Current smoking in adults with asthma are associated with lower socioeconomic status, poor access to care, worse asthma control and poor quality of life. The lower health expenditure among smoking asthmatics is due, at least in part, to a lack of insurance.

Implications for Policy, Delivery, or Practice: Smoking disproportionately affects disadvantaged asthma populations and is associated with poor asthma outcomes. Public health intervention should focus on smoking cessation among these vulnerable subpopulations in adults with asthma.

Poster Session and Number: A, #131

The Effect of Hospital Global Budgeting on Stroke Outcomes: The Mediating Role of Medical Services Use
Yu-chi Tung, National Taiwan University; Guann-Ming Chang, Cardinal Tien Hospital, Fu Jen Catholic University

Presenter: Yu-chi Tung, Ph.D., Associate Professor, Institute of Health Policy and Management, National Taiwan University, yuchitung@ntu.edu.tw

Research Objective: As health care costs keep rising, cuts in reimbursement, such as global budgeting or the Balanced Budget Act in the United States, have become the key to health care reform efforts. Reimbursement cuts are associated with changes in patient outcomes in several studies; however, the mechanism underlying this relationship has received little attention. This study was to assess the mediating role of medical services use in the association between reimbursement cuts and mortality for ischemic stroke; that is, whether the mechanisms underlying the association can be explained by certain items of care.
Study Design: We used the National Health Insurance Research Database, provided by the Bureau of National Health Insurance and managed by the National Health Research Institutes. We identified patients discharged between years 1997 and 2007 with a diagnosis of ischemic stroke based on the International Classification of Diseases, Ninth Revision, Clinical Modification codes. Multilevel logistic and multilevel linear regression analyses were performed after adjustment for patient, physician, and hospital characteristics to determine the associations of reimbursement cuts with medical services use, and 30-day mortality.

Population Studied: There were 310,542 stroke patients admitted to general acute care hospitals in Taiwan over the period 1997 to 2007.

Principal Findings: Larger reimbursement cuts were associated with certain items of care, including less frequent use of physiotherapy assessment, lower reimbursement for nursing care and ward, shorter length of stay, and higher mortality. The use of physiotherapy assessment, reimbursement for nursing care and ward and length of stay mediated the association between reimbursement cuts and higher mortality.

Conclusions: Reimbursement cuts are associated with higher mortality; the association is mediated by certain items of care.

Implications for Policy, Delivery, or Practice: Financial pressure might influence provider’s decision making and result in poor stroke outcomes. Policymakers might need to develop strategies to ensure quality of physiotherapy and nursing care under reimbursement cuts. Quality improvement strategies for stroke care include establishing national protocols and guidelines, restructuring the fee-for-service schedule by increasing fees for deficient care associated with outcomes, or implementing a pay-for-performance initiative.

Poster Session and Number: A, #132

Is there a Link between Using Silver Coated Urinary Catheters and Lower CAUTI Rate?
Derrick Tung, University HealthSystem Consortium; Cindy Abel, University HealthSystem Consortium; MaryBeth Flynn Makic, University of Colorado; Theresa Hulett, University of Colorado; Liang Fei Jordan, University of Colorado Hospital; Joseph Cummings, University HealthSystem Consortium; Andrew Swiontoniowski, University HealthSystem Consortium

Research Objective: Catheter-associated urinary tract infections (CAUTI) are the most frequent health-care related infections in acute care hospitals. University of Colorado Hospital staffs reported utilizing silver coated urinary catheters for a length of time before moving away from silver with no significant impact on urinary tract infection rates. Given Colorado’s success and evidence, we turned to UHC’s databases to better understand the prevalence of silver coated urinary catheter purchases (SpendLINK®) and patient outcomes (Clinical Data Base) to review whether any relationship existed between specific products and patient outcomes. Establishing a relationship between a medical device and quality care is the ultimate goal in proving the value of enhanced products that have been pushed into the supply market.

Study Design: A correlational analysis was conducted using outcomes data obtained from UHC’s Clinical Data Base/Resource Manager (CDB/RM) and SpendLINK®, a tool comprised of reporting modules including price benchmarking and Base MSDRG opportunity reports. Data from the two sources were linked by hospital identification number. The analysis looked for a positive relationship between the percent of urinary catheter spend that was for silver-coated devices versus the CAUTI incidence rate. The data set compared 45 member hospitals in both SpendLINK® and CDB/RM system by silver coated urinary catheters and non-silver coated urinary catheters purchase patterns to hospitals’ CAUTI rate.

Population Studied: The study reviewed FY2010 amounts of hospital-level data for the rate of silver-coated catheter supply spend from SpendLINK® against the rate of CAUTI from the CDB/RM for discharge in FY2010. Data from 45 member hospitals between the two database sets were reviewed, with 76,000+ purchase order records pulled from UHC’s SpendLINK® to determine percentage of silver spend in urinary catheters and twelve months of 2010 patient level data to determine CAUTI rate. The numerator for the rate was defined by adult discharges with a principal or secondary diagnosis code of 996.64 and not present on
admission or all cause readmissions within 7 days with a principal or secondary diagnosis code of 996.64 with present on admission. The denominator was adult discharges.

**Principal Findings:** By analyzing both hospital purchases and patient outcomes databases, we found no correlation between purchase patterns of silver foley catheter and CAUTI rates. Of the 45 hospitals analyzed, CAUTI rate varied between 0.06 and 4.49, while percentage of spend on silver coated catheters varied between 0% and 90%. The R² value between CAUTI rate and percentage of silver spend was 0.0402. On further analysis, we found potential cost savings of 1.99 million dollars in FY2010 ranging from $258 to $151,919 among 35 hospitals associated with moving away from silver while staying with their current supplier. Across the 35 hospitals, there was a mean potential cost saving of $57,142 and a median potential cost savings of $49,796.

**Conclusions:** The analysis of percentage of silver coated catheters purchases compared to CAUTI rate did not exhibit a positive relationship between spending levels and lower CAUTI rate. UHC believes that moving away from silver coated urinary catheter purchases may have significant cost benefits for some hospitals.

**Implications for Policy, Delivery, or Practice:**

**Health Insurance for the Unemployed: The Risk of Unemployment Related Coverage Changes**

Namrata Uberoi, The Pennsylvania State University; Pamela Farley Short, The Pennsylvania State University

**Presenter:** Namrata Uberoi, MPH, PhD Candidate, Health Policy and Administration, The Pennsylvania State University, namrata@psu.edu

**Research Objective:** The Affordable Care Act (ACA) expands sources of health insurance coverage and creates health insurance exchanges. Nonetheless, the Congressional Budget Office estimates that employer-sponsored insurance (ESI) will continue to be the cornerstone of health insurance coverage, covering 60 percent of Americans. Consequently, changes in employment will continue to cause gaps and transitions in health insurance. The risk of unemployment differs by income. The risk of losing one’s coverage as a result of employment loss also differs by income.

This study examines coverage changes related to employment loss at income levels distinguished by the ACA: less than 138 percent FPL (low), 138-399 percent FPL (middle), and greater than or equal to 400 percent FPL (high).

**Study Design:** This study utilizes data from the 2004 and 2008 Survey of Income and Program Participation and examines individuals’ employment and coverage losses. An employment loss is characterized as going from employed in one month to unemployed in the subsequent month. We examined the monthly risk of employment loss for working adults by income. We then examined coverage in the months before and after employment losses by income.

**Population Studied:** Working adults, ages 18 to 64.

**Principal Findings:** In monthly data, 44 percent of low-income, 20 percent of middle-income, and 5 percent of high-income workers were uninsured. Insurance through one’s current employer increased with income – 27 percent of low-income, 65 percent of middle-income, and 83 percent of high-income workers had ESI. In the month prior to becoming unemployed, 40 percent of the unemployed were uninsured. Of those uninsured, 41 percent were low-income, 47 percent were middle-income, and 13 percent were high-income workers. Twenty-eight percent of individuals who experienced an employment loss had ESI after becoming unemployed. Among individuals with ESI, 10 percent were low-income, 46 percent were middle-income, and 44 percent were high-income. Among low-income individuals who were uninsured after becoming unemployed, 85 percent were uninsured and 6 percent had ESI when employed. Among middle-income individuals who were uninsured when unemployed, 72 percent were uninsured when employed and 15 percent had ESI. For high-income persons who were uninsured when unemployed, 57 percent were uninsured and 23 percent had ESI when working.

**Conclusions:** Seventy-four percent of individuals who are uninsured after losing their jobs were uninsured when employed. Middle and high-income workers are more likely to have ESI and consequently are at greater risk of losing health insurance when they experience an employment loss.

**Implications for Policy, Delivery, or Practice:** Gaps and transitions in health insurance due to employment loss will continue to be significant in
the health reform environment. The ACA provides some new protections. Low-income workers will be covered by Medicaid in states that expand their Medicaid programs. At the other end of the income distribution, high-income workers will receive no support. While middle-income workers will have the benefit of exchange subsidies, this group will have to adjust where and how they attain coverage. Thus understanding the prior and subsequent coverage of workers who lose their jobs is crucial in implementing coverage expansions, minimizing gaps, and identifying subgroups that will and will not benefit from coverage reforms.

Limited Availability of Major Depressive Disorder Care Coordination and Patient Engagement Quality Measures—Current Challenges to Improved Quality of Care
Elizabeth Walsh, Avalere Health; Kelsey Jones, Avalere Health; Michelle Bruno, Avalere Health; Kristi Mitchell, Avalere Health

Research Objective: Major depressive disorder (MDD) is a prevalent disease that frequently occurs alongside other physical and mental health conditions. Identified by the Centers for Medicare & Medicaid Services (CMS) and National Quality Forum (NQF) in 2009 as a top-20 high-impact condition, there has been a recent proliferation of quality measures focused on MDD. While MDD is often diagnosed in the primary care setting, a number of cases require the active participation of mental health specialists and caregivers. Avalere sought to assess whether care coordination measures for this population exist, and if so, the extent to which they are used in national programs to improve quality of care.

Study Design: To assess the landscape of measures, Avalere created a database of MDD-related measures from sources including NQF, professional societies, and relevant government entities. Avalere mapped these measures to the MDD care continuum to determine whether measures focused on one aspect of care (e.g., screening, treatment) or more broadly supported care coordination across the continuum. We identified whether the available care coordination and patient engagement measures are used in national programs. Finally, we conducted interviews with representatives of guideline and measure developers and a national health plan to understand the role care coordination and patient engagement measures play in improving MDD care.

Population Studied: N/A

Principal Findings: Avalere identified 48 MDD-related measures, of which 8 focus on care coordination or patient engagement. These measures were developed by the American Medical Association-Physician Consortium for Performance Improvement, Institute for Clinical Systems Improvement, and Foundation for Accountability (now a defunct organization). None of the measures are NQF-endorsed or used by national quality improvement programs such as the Physician Quality and Reporting System (PQRS). However, “Adult Major Depressive Disorder: Coordination of Care of Patients with Co-Morbid Conditions – Timely Follow-Up,” was proposed for inclusion in PQRS for 2013 despite lacking NQF endorsement. Targeted interviews suggest that care coordination is essential for effective MDD care. Interviewees highlighted successful MDD quality improvement programs (e.g., Minnesota’s “Depression Improvement Across Minnesota, Offering a New Direction”) that rely on an integrated structure that actively facilitates care coordination and involves patients in their care. However, stakeholders noted that measure development, endorsement, and use of care coordination and patient engagement measures has been difficult for a variety of reasons including the burden of data collection, difficulty testing measures, limited feasibility of implementation, challenges to physician buy-in, and lack of appropriate delivery and incentive structures.

Conclusions: With a recognized need for care coordination to improve patient outcomes, few measures that support this aspect of care are being used by national-level programs. Measure developers cite the difficulty of creating appropriate, feasible measures while users point to the limitations in current delivery structures.

Implications for Policy, Delivery, or Practice: Delivery systems that facilitate care coordination within primary care facilities, such as patient-centered medical homes and Medicaid Health Homes, may provide the greatest opportunity to support improved quality of care for MDD patients. With a focus on care coordination, these new delivery systems may provide the
Biopsychosocial Model of Improved Chronic Health for People Age 50 or Older with Chronic Conditions
Chia-chiang Wang, Northwestern University

Research Objective: About 80% of Americans age 50 or older have at least one chronic condition needing long-term care and rehabilitation services. As people getting older, the numbers of chronic condition they have are expected to be getting higher. Chronic conditions consume 84% of medical expenditures and account for 70% of annual deaths. However, most of chronic conditions are controllable and preventable. Early control or improvement in chronic illness for people age 50-64 could potentially decrease their likelihood of having additional chronic conditions and functional limitations as well as the burden on our healthcare system. A lack of empirical information about how to comprehensively improve chronic illness limits the development of integrated person-centered long-term care and health promotion programs, especially for those who are approaching older adulthood. This project aims to examine both the biological and psychosocial factors that are associated with patient-reported improvement in chronic health. It also seeks to explore the relationships between chronic health, functional limitations, self-rated health, and healthcare utilization.

Study Design: The Health and Retirement Survey (HRS) longitudinal database will be used to evaluate the perspective prediction of biopsychosocial factors on patient-reported improved chronic illness. The HRS has a nationally representative sample of at least 20,000 Americans age 50 or older and it is estimated that 6,500 cases will be selected based on the selection criteria. The outcome variable contains the information about the patient-reported improvement in chronic health of people with diabetes, cancer, heart conditions, arthritis, and lung diseases. Hierarchical logistic regression and Structural Equation Modeling (SEM) will be used to conduct statistical analyses. The major research hypotheses are that biological and psychosocial factors at baseline (2006) predicted improvement in chronic health 2 years later (2008), and that improved chronic health (wave 2) was positively correlated with less posterior functional limitations, better self-rated health, and decreased healthcare utilization/cost (all in 2010).

Population Studied: People age 50 or older with at least one chronic condition or disease.

Principal Findings: Expected findings will indicate the biopsychosocial risk/protective factors of improved chronic health for people with different chronic conditions. The differences in the predictors of improving chronic health among the two age groups (50-64 vs. older adults) will be reported. The data in the goodness-of-fit of the proposed model will be also provided.

Conclusions: This study will provide empirical evidence of how improved chronic health may result in less functional limitations, better self-rated health, and eventually decreased healthcare costs. The development of evidence-based biopsychosocial interventions will then help to reduce unnecessary healthcare utilization and medical expenditures.

Implications for Policy, Delivery, or Practice: This study could guide future longitudinal studies on how biological and psychosocial factors affect the health of aging population with different chronic conditions. Also, expected findings will inform the development of disease-specific biopsychosocial interventions to maintain or promote health of people age 50 or above and ease the increasing burden of our healthcare systems. It will then potentially prevent aging population from having additional chronic conditions to have a smooth and healthy transition to their elderhood and increase their financial security with less medical expenditure.

Who Receives Weight Reduction Advice? A Study of Patient and Provider Factors
Melanie Ward, Project L/EARN; Susan Brownlee, PhD, Rutgers University Center for State Health Policy, Institute for Health, Health Care Policy, and Aging Research

Presenter: Melanie Ward, RWJF Research Intern, Institute for Health, Health Care Policy and Aging Research, Project L/EARN, melaward@umich.edu

Funding Source(s): NIH

Poster Session and Number: A, #136
Research Objective: To determine the factors that influence the likelihood with which adult patients report receiving weight reduction advice from a health provider.

Study Design: Cross-sectional data analysis using the 2009 New Jersey Family Health Survey, a random-digit dialed telephone survey that provides population estimates of health care coverage, access, usage, and other topics relevant to health policy in New Jersey. A four model nested logistic regression was conducted to determine the significant predictors of receipt of advice to lose weight. The primary predictors of interest are Body Mass Index (BMI) classification and self-assessed weight status. Model 1 adds patient demographic and self-reported health status variables. Model 2 adds patient health care utilization patterns, health provider type, and respondent rating of patient-provider communication quality, while Model 3 adds BMI category and self-assessed weight status. The final model adds patient-provider race and gender concordance.

Population Studied: 1,929 adult residents of New Jersey who reported visiting a health provider within the previous two years. Respondents were household members 18 years or older considered the most knowledgeable about the health and health care needs of the household.

Principal Findings: The overall percentage of the sample receiving weight reduction advice from a health provider in the past year was 19.8%. Only 15.9% of overweight and 47.6% of obese respondents reported receiving such advice. Logistic regression results: respondents classified as overweight or obese were more likely to receive advice to lose weight compared to non-overweight respondents (OR=2.08, 5.91, respectively), as were respondents who perceived themselves as slightly overweight or very overweight (OR=4.74, 13.89 respectively). Respondents ever diagnosed with diabetes or asthma were more likely to receive advice to lose weight while those with any other chronic disease were less likely. Higher education levels, greater frequency of doctor visits over a 12-month period, and visiting a public clinic as a usual source of care were associated with a greater likelihood of receiving advice to lose weight, while female gender and higher respondent ratings of patient-provider communication quality were associated with a lower likelihood. Age, race, income, marital status, household language, citizenship status, weight-related health symptoms, insurance type, specialist visits, the number of year respondents visited their regular doctor, provider type, and race or gender concordance were not significant predictors of advice receipt.

Conclusions: These findings indicate that many health providers are not initiating weight-reduction discussions with the majority of their patients, even when these patients are clinically overweight or obese. It is essential to understand the barriers faced by providers in offering weight reduction advice to their patients.

Implications for Policy, Delivery, or Practice: The U.S. Preventive Services Task Force (2003) recommends that health providers refer overweight and obese patients to behavioral and nutritional counseling services for weight reduction. The Institute of Medicine (2012) has called for incentives for regular obesity prevention, screening, diagnosis, and treatment by health providers. Such practice incentives to increase the rate at which physicians advise weight reduction and refer patients to counseling services may be necessary to achieve these objectives.

Angina Visits in the Outpatient Setting

Julie Will, Centers for Disease Control and Prevention; Fleetwood Loustalot, PhD, FNP, CDC, Division for Heart Disease and Stroke Prevention; Yuling Hong, MD, PhD, CDC

Presenter: Julie Will, PhD, MPH, Senior Epidemiologist, Division for Heart Disease and Stroke Prevention, Centers for Disease Control and Prevention, jxw6@cdc.gov

Research Objective: “Preventable hospitalizations for angina” has been used as an indicator of failed care in the ambulatory care setting. Rates of these hospitalizations have been rapidly decreasing since the late 1980s which may be a reflection of better care in the outpatient setting- possibly resulting in increasing rates of angina in outpatient settings. We use nationally representative samples of visits to outpatient departments and nonfederal office-based physicians to describe rates of angina and to describe trends over a 16-year period.

Study Design: Age- and sex-stratified rates were calculated using ICD-9 codes detailed in the technical specifications for preventable hospitalization for angina published by the Agency for Healthcare Research and Quality.
which uses data from the U.S. Census Bureau as the denominator for the rates. These specifications require that transfers and certain cardiac procedures be excluded; however, these exclusions did not apply to this outpatient analysis. Data are from the 1995-2010 National Ambulatory Care and National Hospital Ambulatory Care Surveys which are stratified, probability designed surveys with multiple stages of sampling.

**Population Studied:** Patient records were systematically selected over randomly assigned reporting periods from outpatient departments and physician offices. Visit information from these records were combined and used to produce population-based rates of angina for adults aged 18 years and older.

**Principal Findings:** Crude visit rates for men aged 18-64 years dropped significantly from the first study period (1995-1998) to the third period (2003-2006), and then increased in the final period (2007-2010). For women aged 65 years and older, the rates dropped from 1995-1998 (6,649/100,000; 95% CI 5,100-8,217 per 100,000) to 2007-2010 (3,021/100,000; 95% CI 1,835-4,208 per 100,000). For men aged 65 years and older, rates also declined during this same time from 8,533/100,000 (95% CI 6,608 to 10,458/100,000) to 4,079/100,000 (95% CI, 2,019-6,138 per 100,000). Age- and sex-standardized rates for these visits have been reduced by about 50% over 16 years--showing a statistically significant linear decline (p<.0001).

**Conclusions:** As seen with preventable angina hospitalizations, population-based rates of angina have declined substantially in the outpatient setting. Most of this change is observed in those aged 65 years and older. Future research should focus on determinants of angina rate declines in both inpatient and outpatient settings. This may require mixed methods research employing both quantitative and qualitative analyses.

**Implications for Policy, Delivery, or Practice:** Explanations for the decline in preventable hospitalization rates for angina have centered on the increased use of sophisticated diagnostic technologies likely resulting in diagnoses more specific than angina. It is unlikely that such sophisticated equipment is currently being used in the outpatient setting. Understanding whether these declines have resulted from factors such as new guidance, provider behaviors, or reimbursement practices may have important implications for creating efficiencies and cost savings in the U.S. health care system.

**Streamlining of Operating Room for Living Donor Liver Transplantation**

Daniela Ladner, Northwestern University; Donna Woods, Northwestern University; Rebecca Khorzad, Northwestern University; Teri Strenski, Northwestern University; Amna Daud, Northwestern University; Kathryn Waltzman, Northwestern University; Tija Berzins, Northwestern University; Jane Holl, Northwestern University

**Presenter:** Donna Woods, PhD, Northwestern University, woods@northwestern.edu

**Research Objective:** Living donor liver transplantation (LDLT) is highly complex and therefore vulnerable to systems and processes inefficiencies that can compromise patient care. Inefficiencies in care have been associated with increased medical errors and preventable complications. The setup of the operating room and preparation for surgery up until incision is fairly standardized and directed towards preparing the patient and the surrounding for a lengthy surgery. In order to assess the efficiency of the OR system, we performed a systems engineering assessment of the OR setup at three LDLT centers.

**Study Design:** As part of a 5-year LDLT patient safety study (R01DK090129) OR setup was video recorded at 3 Adult-to-Adult living Donor Liver Transplant Centers (A2ALL) (Lahey, Northwestern, VCU) to examine the process cycle efficiency. Set up was defined from first nurse entering the OR for preparation until incision is performed. A seasoned process engineer analyzed the data and identified 10 steps that were used to create current state value stream maps. Value-Added Time (VAT) [defined as time directly spent with the patient creating change], Total Cycle Time (TCT) [total time for OR setup], and Cycle efficiency time (CET) were calculated for each center.

**Population Studied:** Clinicians and medical personnel involved in the care of the living donor liver transplant patients

**Principal Findings:** The 10 process steps identified were: 1. Supplies/equipment verification 2. Supplies/equipment positioning part one 3. Count 4. Supplies/equipment positioning part two 5. Patient positioning and sign in 6. Airway management 7. Lines placement 8. Intubation (gastric) 9. Creation of
Sterile fields 10. Timeout. Steps 6, 7, and 8 were considered value-added time. TCT ranged from 81-182 min, VAT ranged from 19-68 min and (PCE) ranged from 12% to 58% between sites. Step 8 (‘intubation’) had the highest range 3 min-52 min.

**Conclusions:** There was considerable inter-site variability for TCT, VAT and PCE, suggesting ample opportunity for process optimization and streamlining. Process optimization reduces variability (range) and thereby reduces vulnerability to errors.

**Implications for Policy, Delivery, or Practice:**
Streamlining can reduce wastage of resources (i.e., human, material) and as demonstrated in other setting has the potential to reduce errors and preventative complications for vulnerable LDLT patients.

**Funding Source(s):** NIH

**Safety Risks in Living Donor Liver Transplantation**

Donna Woods, Northwestern University; Tija Berzins, Northwestern University; Elizabeth Pomfret, Lahey Clinic; Robert Brown, Columbia University; Robert Fischer, Virginia Commonwealth University; Amna Daud, Northwestern University; Kathryn Waltzman, Northwestern University; Daniela Ladner, Northwestern University

**Presenter:** Donna Woods, PhD, Northwestern University, woods@northwestern.edu

**Research Objective:** According to the 2010 U.S. Office of the Inspector General’s Report, adverse events (AE) are common in the care of patients. In Living Donor Liver Transplantation (LDLT), given that living donors are healthy volunteers undergoing a major procedure purely for altruistic reasons, without any direct benefit for their own health, prevention of such events is particularly important, when caring for living donors and for the recipients to which they are donating. To inform critical targets for improvement to reduce AEs, we performed a review of medical records at four LDLT centers, to identify AEs as well as systems and process errors.

**Study Design:** Retrospective Medical Record Review

**Population Studied:** Paper and electronic medical records were collected from large transplant centers including documentation for the period of admission for transplant through discharge, plus any readmissions within 30 days. Systematic in depth medical record review was performed for 41 medical records (21 donor records and 20 recipient records) by a trained research nurse reviewer. All issues identified were reviewed by transplant surgeons to determine if an AE occurred. AEs were defined as an injury caused by medical management, rather than by the underlying disease.

**Principal Findings:** In the 41 reviewed records 727 issues were identified (313: donors, 414: recipients). The site distribution: A= 213, B=196, C= 94 and D= 224. Recipients had a mean of 21 issues (7-49) and donors had a mean of 14 (5-44). Twenty-eight percent (n=208) of issues were determined to be AEs: 42% (88) occurred in the care of donors, 58% (120) in the care of recipients. At least one AE occurred in the care of 100% of the donor and 100% of the recipients. The average number of AEs was 4.2 in donors and 6 in recipients. The most common types of AEs were related to Diagnostic (i.e. respiratory failure), Infections (i.e. UTI), Medications/Infusions (i.e. anaphylaxis), and Count Reconciliation leading to sequelae for the patient.

**Conclusions:** This study demonstrates that AEs were common in LDLT. Given the results that AEs occurred in the care of 100% of donors and in the care of 100% of recipients it is critical to address these patients’ risks.

**Implications for Policy, Delivery, or Practice:**
These data can provide guidance to direct toward targets for improvement to reduce AEs and improve the overall safety and care outcomes of LDLT.

**Survival of Patients with Triple-Negative Breast Cancer Using EMR Linked Cancer Registry Data**

Hong Xiao, Florida A&M University; Fei Tan, Indiana University-Purdue University Indianapolis; Youjie Huang, Bureau of Epidemiology, Florida Department of Health; Jason Feldman, Bureau of Epidemiology, Florida Department of Health; Leonidas Koniaris, Jefferson University Hospitals, Thomas Jefferson University; Sriharsha Gummadi, Jefferson University Hospitals, Thomas Jefferson University; Georges Adunlin, Florida A&M University; Askal Ali, Florida A&M University
Presented: Hong Xiao, Ph.D., Professor, College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, hong.xiao@famu.edu

Research Objective: Triple-negative of biomarkers (estrogen receptor-negative, progesterone receptor-negative and HER2-negative) is a high-risk breast cancer that lacks the benefit of specific therapy that targets these proteins. This study intended to investigate survival among triple-negative breast cancer patients.

Study Design: Electronic medical records from a network of 9 hospitals were linked to female breast cancer patients diagnosed between 2007 and 2010 in Florida. Bivariate and multivariate survival analyses using the Cox model were conducted. Nonparametric survival curves for race were generated using Kaplan-Meier method (KM).

Population Studied: Female breast cancer patients diagnosed in Florida between 2007 and 2010 were included in the study.

Principal Findings: The study population consisted of 4,220 breast cancer patients. The estimated two-year survival was 95.1%. The median follow-up time for those who died due to breast cancer was 569 days. Log-rank test indicated survival functions between blacks and non-blacks were significantly different over time (p < 0.0001). KM survival curves revealed that survival probability for blacks was lower than that of non-blacks after diagnosis. Hazard of breast cancer death for patients with triple-negative and patients with unknown triple-negative status were 4.34 and 2.35 times that of non-triple negative patients, respectively. Death rate among blacks was 1.6 times the rate among non-blacks over time. Other factors associated with an increased hazard over time were being diagnosed in regional stage or having unknown diagnosis stage, having poorly or undifferentiated tumor, being a Medicare beneficiary, being single, with larger tumor size, and with more positive nodes detected. Immediately after diagnosis distant stage and more comorbidity conditions were associated with an elevated risk, whereas more nodes examined was associated with reduced risk of breast cancer death. Effects of distant stage, total comorbidity, and total lymph nodes examined gradually attenuated over time.

Conclusions: Our results confirm that black women have worse breast cancer survival compared to non-black women. Women with triple-negative breast cancer have the worst outcomes in survival. Hospital EMR linked cancer registry data allows investigations of breast cancer patient outcomes in a more comprehensive way.

Implications for Policy, Delivery, or Practice: There is an urgent need for clinicians, patients, researchers, and regulatory agencies to work together to facilitate research in triple-negative breast cancer populations. Integration of Cancer Registry Data and Hospital Electronic Medical Records should be supported to enhance data for better research to reduce the morbidity and mortality due to cancer and other co-morbidities.

Comparing Performance Quality Under a State-of-Art Colonoscopy Protocol vs. Typical Endoscopy Protocols - Implications for Colorectal Cancer Protection
Sudha Xirasagar, University of South Carolina; Yi-Jhen Li, MHA, University of South Carolina; Thomas G. Hurley, MS, University of South Carolina; Chaiporn Punkam, PhD, Food and Drugs Administration, Government of Thailand; James Hardin, PhD, University of South Carolina; James R. Hebert, Sc.D, University of South Carolina

Presented: Sudha Xirasagar, Ph.D., Associate Professor, Health Services Policy and Management, University of South Carolina, sxirasagar@sc.edu

Research Objective: Using Year 1 data from a short-term South Carolina program to fund screening colonoscopies for the indigent (SCOPE-SC), we compare adenoma detection rates and characteristics at Site-3, implementing a high polyp-yield-optimized protocol) with comparison sites (typical community-based endoscopy centers) and discuss the cancer protection implications.

Study Design: A concurrent comparison of a colonoscopy provider site using a polyp-maximizing clinical protocol (Site 3) with the remaining 3 provider sites participating in the program in 2009-09.

Population Studied: Polyp and adenoma yields were studied among 665 program clients of uniformly low SES served, 325 at Site 3 and 340 at Sites 1, 2 and 4 (comparison sites) together.

Principal Findings: Race and gender composition were similar in the two groups.
Percent of patients with polyp(s) were 78.4% at Site 3 and 35.3% at comparison sites, and with adenoma(s) 37.5% and 18.2% (both p<0.001). A total of 338 adenoma(s) were removed, 252 at Site 3 and 86 at comparison sites for a Mean Number of Adenomas per patient screened (MNA) of 0.78 and 0.26 respectively, p<0.001. Proportions of adenomas among polyps (PAP) were similar in both groups, 35.3% and 42.1% indicating that missed polyps at comparison sites may be proportional to missed adenomas. Differences in adenoma numbers by size were as follows: MNA 0.59 vs. 0.16 for =5 mm adenomas, p<0.001); MNA 0.11 vs. 0.05 for 6-9 mm adenomas, p<0.01), and no difference for large adenomas. The percentages of adenomas with advanced histology (high grade neoplasia, villous, tubulovillous, serrated, or carcinoma) were similar in the two groups, 9.9% vs. 12.8%. Further the percentages of small, medium and large adenomas showing advanced histology were similar. One 2 mm adenoma was an invasive carcinoma.

**Conclusions:** In a uniform SES, race and gender composition sample, we find that a high-polyp detection maximizing protocol resulted in higher adenoma detection rates. Importantly the adenoma size categories that were detected at much higher rates at Site 3 showed a similar percentage of histologically advanced lesions at both site groups. The disproportionately high frequency of small adenomas at Site-3, coupled with the similarity of advanced histology percentages at the two side groups (regardless of size), together with the finding of invasive malignancy in one 2 mm adenoma lead us to conclude that procedures performed at comparison sites may have conferred lower cancer protection than those performed at Site 3. High rates by Site 3 may validate the utility of its state-of-art protocol to enhance lesion detection and removal.

**Implications for Policy, Delivery, or Practice:**
The innovative elements of the protocol of Site-3 should be studied further to potentially include the critical elements in colonoscopy practice guidelines by the professional societies with appropriate payer adjustments to cover the costs of providing these innovative elements.

**Hospital Center Effect for Laparoscopic Colectomy among Elderly Stage I-III Colon Cancer Patients**

Zhiyuan Zheng, University of Maryland School of Pharmacy; Nader N Hanna, MD, University of Maryland School of Medicine; Eberechukwu Onukwugha, PhD, University of Maryland School of Pharmacy; Kaloyan Bikov, BS, University of Maryland School of Pharmacy; C. Daniel Mullins, PhD, University of Maryland School of Pharmacy

**Presenter:** Zhiyuan Zheng, Ph.D., Postdoctoral Fellow, Pharmaceutical Health Services Research, University of Maryland School of Pharmacy, jzheng@rx.umaryland.edu

**Research Objective:** Surgical outcomes are associated with patient and surgeon characteristics. If outcomes are also independently impacted by the specific hospital where the surgery occurs, there is a hospital center effect (HCE). This study is to examine HCE among elderly stage I-III colon cancer patients with laparoscopic colectomies.

**Study Design:** Multilevel regressions were utilized to study potential HCE for length of stay (LOS), 30-day re-hospitalization, and in-hospital mortality, adjusting for patient, surgeon and hospital level characteristics. To quantify the impact of HCE, we calculated median instantaneous rate ratio (MIRR) for LOS and median odds ratio (MOR) for in-hospital mortality and 30-day re-hospitalization. Sensitivity analyses were also conducted for high volume/medical school affiliated hospitals and colorectal surgeons.

**Population Studied:** The Surveillance, Epidemiology and End Results (SEER)-Medicare dataset was used to identify stage I-III colon cancer patients in 2003 to 2007 with laparoscopic colectomies.

**Principal Findings:** The multilevel analyses based on 4,617 patients from 465 hospitals documented significant HCEs for LOS (MIRR = 1.36; p less than .001) and in-hospital mortality (MOR = 1.72; p equal to 0.037), but no HCE for 30-day re-hospitalization. For patients with Charlson comorbidty index (CCI) greater than or equal to 3, MIRR rose to 2.27 for LOS and MOR rose to 6.87 for in-hospital mortality, as compared to patients with CCI = 1. The sensitivity analyses confirmed our findings. HCE was significant for LOS in all subgroup analyses, and was significant for in-hospital mortality for high volume/medical school affiliated hospitals.
Conclusions: HCE is an important source of variation for the short-term outcomes of laparoscopic colectomies, and it is still significant when patient, provider and hospital level characteristics are adjusted. HEC exist for both LOS and in-hospital mortality. The findings are robust to high volume/medical school affiliated hospitals and colorectal surgeons.

Implications for Policy, Delivery, or Practice: Hospital center effect is a potential area to improve the quality of care for stage I-III laparoscopic colon cancer patients.

Association between Overall Incremental Cost and Survival Benefit of Second Line Chemotherapy/Biologics Treatment among Elderly Medicare Metastatic Colon Cancer Patients

Zhiyuan Zheng, University of Maryland School of Pharmacy; Nader N Hanna, MD, University of Maryland School of Medicine; Eberechukwu Onukwugha, PhD, University of Maryland School of Pharmacy; Kaloyan Bikov, BS, University of Maryland School of Pharmacy; Brian Seal, PhD, MBA, RPh, Bayer HealthCare Pharmaceuticals, Inc.; C. Daniel Mullins, PhD, University of Maryland School of Pharmacy

Presenter: Zhiyuan Zheng, Ph.D., Postdoctoral Fellow, Pharmaceutical Health Services Research, University of Maryland School of Pharmacy, jzheng@rx.umaryland.edu

Research Objective: To examine the overall incremental cost and survival benefit associated with the receipt of second line chemotherapy/biologics (Tx2) among elderly Medicare metastatic colon cancer (mCC) patients who had received first line chemotherapy/biologics treatment (Tx1).

Study Design: Cox regression and partitioned least squares regression were utilized to obtain the incremental survival benefit and the overall incremental cost associated with the receipt of Tx2 within a five-year period, respectively. The regressions controlled for patient demographic and clinical characteristics including cancer related measures, Charlson comorbidity index and proxy for poor performance status. Bootstrapping was used to produce 95 percent confidence intervals (CI).

Population Studied: Elderly (66+) SEER-Medicare patients diagnosed with mCC in 2003-2007 were identified and followed until death or Dec 31, 2009. The analysis was restricted to patients who received any chemotherapy/biologics treatment.

Principal Findings: Of the 3,266 elderly Medicare mCC who received Tx1, 2,744 (84 percent) died within the observation period; 1,440 (44 percent) received Tx2; 274(8 percent) received subsequent treatments. The incremental survival benefit associated with the receipt of Tx2 was 0.631 years (CI: 0.517 - 0.761), and the associated overall incremental cost was 107,027 dollars (CI: 93,401 - 120,887). The incremental cost-effectiveness ratio for Tx2 was 169,722 dollars per life year gained (CI: 137,139 - 208,134).

Conclusions: The estimated survival benefit of receiving second line chemotherapy/biologics treatment ranges from 6 to 9 months, which is consistent with evidence from clinical trials. This improved survival was associated with costs that are slightly above 100,000 dollars.

Implications for Policy, Delivery, or Practice: It is consistent with the evidence from clinical trials that the survival benefit of receiving second line chemotherapy/biologics treatment is substantial, so is the associated overall incremental cost that patients incur during second line treatment

HEALTH CARE WORKFORCE

Comparative Assessment of Physician and Non-Physician Productivity in Provider-Based Rural Health Clinics: A Factorial Invariance Approach
Abiy Agiro, WellPoint; Thomas T.T.H Wan, PhD; MHS, University of Central Florida; Judy Ortiz, PhD MBA, University of Central Florida

Presenter: Abiy Agiro, Ph.D.,M.H.S.,B.Sc., Senior Research Analyst, HealthCore, WellPoint, abiyagiro@gmail.com

Research Objective: CMS requires physician and non-physician (physician assistant and/or nurse practitioner) productivity standards on independent Rural Health Clinics (RHCs). Given the absence of productivity standards on provider-based RHCs, comparing the productivity of health practitioners for these clinics would be of interest.

Study Design: Data for provider-based RHCs were obtained from CMS Cost Reports. Latent variable modeling was utilized to assess productivity as a latent construct. Productivity was indirectly measured through four Data Envelopment Analysis (DEA) scores: 1) categorical DEA scores that take into account the level of social disadvantage faced by provider-based RHCs, 2) 'super-efficiency'-oriented DEA scores to address the extent and magnitude of DEA score changes in less productive practitioners on the bases of productive practitioners, 3) slacks-based-non-oriented DEA scores to incorporate underutilization or overutilization of input resources, and 4) non-discretionary DEA scores with input and output control variables. The four DEA scores reflected the three major categories of DEA models (radial, non-radial and oriented, non-radial and non-oriented). Utilizing the RUCA four level classifications of rural areas, DEA scores were computed separately for practitioners falling in the same rural classification. The input variable for physician productivity DEA models was total physician FTEs while the output variable was total physician visits (controlling for total non-physician FTE inputs and total non-physician visit outputs). Non-physician productivity was assessed in similar manner. To account for population-level risk differences, the sum of mortality rates for the four leading causes of deaths at county level was divided by the national sum of mortality rates for the same causes of deaths. DEA scores were multiplied with the aforementioned cause-specific mortality rate. The reliability and validity of physician and non-physician productivity latent variable models were assessed. Next, a multi-group latent variable model was applied to physician and non-physician productivity models to identify measurement and structural differences.

Population Studied: The study included 30% (N=509) of all provider-based RHCs in the U.S. for 2007 (N=1,701).

Principal Findings: We find that (1) latent measure of productivity for non-physicians had construct validity (Chi-square [2, N = 509] = 2.922, p = .232, RMSEA = .030, CFI = 1.000) and was reliable (reliability coefficient = 0.8998); (2) latent measure of productivity for physicians had construct validity (Chi-square [1, N = 509] = 4.371, p = .037, RMSEA = .071, CFI = .999) and was reliable (reliability coefficient = 0.8640); and, (3) latent variable models of physicians and non-physicians showed full measurement and structural variance.

Conclusions: In provider-based RHCs, physician and non-physician productivity levels differed from each other. A key limitation was the absence of case-mix adjustments.

Implications for Policy, Delivery, or Practice: The poor factorial invariance of physician and non-physician latent variable models indicated the need to assess the productivity of each practitioner through different measures. In other words, defining productivity as the maximization of outputs (visits/encounters) while minimizing inputs (FTE labor) is biased since physicians generally deal with more acute visits than non-physicians.

Critical Tasks and Challenges Associated with Initiating Care Transitions for Hospitalized Patients Receiving Skilled Home Healthcare Services after Hospital Discharge
Alicia Arbaje, Johns Hopkins University

Presenter: Alicia Arbaje, M.D.,M.P.H., Assistant Professor Of Medicine, Associate Director Of Transitional Care Research, Department of Medicine, Johns Hopkins University, aarbaje@jhmi.edu

Research Objective: For reasons that are poorly understood, patients who require skilled home healthcare (SHHC) services after hospital
discharge (e.g. home nursing, physical therapy) are among those at highest risk of hospital readmission. The care transition to SHHC is often initiated by hospital-based discharge planners or home care coordinators (HCCs). Ensuring that HCCs provide the SHHC agency with relevant patient information is critical for a successful care transition, yet little is known about HCC workflow. The aim of the study was to (1) identify critical tasks in HCC workflow, and (2) identify challenges faced by HCCs in coordinating care for those requiring SHHC services after hospital discharge.

**Study Design:** The conceptual framework guiding this study is the Systems Engineering Initiative for Patient Safety model, based on the field of human factors and systems engineering, which can be used to proactively understand risks in complex systems. We used qualitative research methods using ethnographic techniques (direct observations and interviews) to extract process and systems level information about HCC workflow.

**Population Studied:** HCCs and associated staff (n=15) were shadowed within an SHHC agency and on 9 medical and surgical units in two hospitals and a skilled nursing facility within an academic health system. Data collection took place during multi-disciplinary rounds, patient bedside visits, and office work involving development and transmittal of referrals to the SHHC agency.

**Principal Findings:** We identified several critical tasks in HCC workflow to refer patients to SHHC: a) identify eligible patients; b) collect relevant information; c) perform bedside patient visits; d) complete paperwork; e) provide patient education; f) contact the receiving SHHC agency; g) schedule follow-up patient visits; and h) transmit referral package to SHHC agency. These steps were often not done in chronological order due to time constraints, limited access to information, and challenges associated with timely communication with nurses, patients and skilled nursing facilities. Four primary challenges were identified for HCCs in completing these tasks: 1) locating and identifying relevant patient information from various sources; 2) access to physicians for prescriptions and orders; 3) inadequate support to track progress of multiple concurrent referrals; and 4) uncertainty of care plans due to changes in patient status.

**Conclusions:** This study characterized critical tasks and challenges in the initiation of patients’ care transitions from the hospital to the SHHC setting. Future studies are needed to track patients as they receive SHHC services after discharge to identify additional challenges in care delivery.

**Implications for Policy, Delivery, or Practice:** Those receiving SHHC after hospital discharge remain at high risk for early hospital readmission, but few studies focus on improving care for this vulnerable population. The challenges identified could pose a risk to patient safety and quality of care, and these could be targets for intervention. For example, information technology solutions could alleviate challenges associated with locating relevant patient information. Multitasking is required of HCCs, and tracking and coordination tools could reduce cognitive workload associated with multiple concurrent referrals. These findings have implications for SHHC agencies, discharge planners, and health systems interested in improving transitional care for those with complex needs.

**Changes in Primary Care Physician Productivity over Time: Is there Evidence of Physician Burnout in Response to the Current Practice Environment?**

Carine N. Yelibi, Massachusetts General Hospital; Steven Atlas, Massachusetts General Hospital; Jeffrey M. Ashburner, Massachusetts General Hospital; Wei He, Massachusetts General Hospital; Steven J. Atlas, Massachusetts General Hospital

**Presenter:** Steven Atlas, M.D., Director, Primary Care Practice-based Research And Quality Improvement, General Medicine Division, Massachusetts General Hospital, satlas@partners.org

**Research Objective:** Despite evidence that systems with a strong primary care foundation provide better care at a lower cost, interest in careers in primary care have decreased among U.S. medical school graduates. Many factors contribute to changes in the physician workforce, but dissatisfaction with the current practice environment has been reported. We sought to examine changes in primary care physician (PCP) productivity measures over time and whether there were differences among PCPs based upon years in practice.
Study Design: We examined provider productivity among staff PCPs who practiced within a large, academic primary care network over a four-year period between 2009 and 2012. Eligible PCPs included those practicing in 2009 and who remained in the network for at least 2 additional years. Productivity measures were assessed on an annual basis using data from electronic scheduling and billing systems and included outpatient office hours worked per week based upon a 28 hour full-time equivalent (FTE) model, outpatient visits per FTE (Visits/FTE) and PCP’s patient panel per FTE (panel/FTE). PCPs were categorized into tertiles at baseline based on the number of years since medical school graduation (<15, 15-24, or >24 years) to examine whether years of experience were associated with changes in productivity. We examined unadjusted productivity measures over time among all PCPs and among PCPs stratified by years since graduation. We used repeated-measures linear mixed effects models to assess the impact of time and the interaction between time and tertiles of PCP years since graduation on adjusted productivity measures after controlling for physicians’ gender and practice type (community health center or not).

Population Studied: PCPs within an academic primary care network.

Principal Findings: Among 155 PCPs, those with less than 15 years since graduation (n=51) were more likely to be female (59% vs. 50% [15-24 years, n=54] and 46% [>24 years, n=50], p=0.03) and more likely to work at a community health center (45% vs. 28% [15-24 years, n=54] and 24% [>24 years, n=50], all p<0.001). Overall, between 2009 and 2012, PCP FTEs declined 4% from 0.55 to 0.53 (p=0.01), the number of visits/FTE increased 6% from 3110 to 3303 (p<0.001), and panels/FTE decreased slightly from 1466 to 1451 patients (p=0.7). After stratifying PCPs into tertiles by years since graduation, unadjusted and adjusted productivity measures were not different from the trends among all PCPs combined.

Conclusions: Among PCPs practicing within a single, academic primary care network between 2009 and 2012, clinical hours decreased 4% and outpatient visits increased 6%, but there was no change in the size of PCP patient panels over a three year period. Productivity measures did not differ among PCPs according to the years since medical school graduation.

Implications for Policy, Delivery, or Practice: We did not find evidence that the current primary care practice environment is associated with differences in physician productivity measures among veteran primary care physicians compared to more recent medical school graduates.

Preparing an Inter-Professional Health Care Workforce
Juanyce Taylor, PhD, University of Mississippi Medical Center; Jess Bailey, University of Mississippi Medical Center; Ellen Jones, PhD, University of Mississippi Medical Center; Jessica Bailey, PhD, University of Mississippi Medical Center

Presenter: Jess Bailey, Ph.D., M.S., B.S., Interim Dean, School of Health Related Professions, University of Mississippi Medical Center, jhbailey@umc.edu

Research Objective: We sought to investigate how participating in inter-professional educational programs, both on-line and in a traditional classroom/laboratory format, could be a transformative learning experience.

Study Design: A qualitative observational study was initiated, using reflective writings by students who were provided a prompt from the researchers, to provide evidence of lived experiences in inter-professional educational settings.

Population Studied: A purposeful sampling of students at an academic health science center in the southeastern United States with a School of Allied Health Professions containing nine discipline specific programs was conducted. The School offers doctorate degrees in Clinical Health Sciences, Physical Therapy, and Health Administration; master degrees in Occupational Therapy, Health Informatics and Information Management, and Health Sciences; and bachelor degrees in Radiologic Sciences, Medical Laboratory Science, Health Sciences, Health Informatics and Information Management, Cytotechnology and Dental Hygiene. A post-baccalaureate certificate in Nuclear Medicine is also offered. Inter-professional education offerings are provided at the bachelors, masters, and doctoral levels of these educational programs.

Principal Findings: The opportunity to learn in an inter-professional setting promoted a culture for students that simulated the real-world health care environment. Students wrote about significant learning experiences that enabled
them to adapt to seeing the workplace through a new lens that provided a broader perspective.  

**Conclusions:** Creating an inter-professional educational setting improves student understanding of a coordinated care team, supports a patient-centered focus, and improves relationships among distinct disciplines. Classroom and field experiences that are inter-professional better prepare students for the health care workforce.

**Implications for Policy, Delivery, or Practice:** The Affordable Care Act (ACA) encourages coordinated approaches to health care provided by a team of efficient health care providers. There are provisions in the ACA intended to strengthen the current primary care workforce and to build the future workforce. By providing inter-professional educational opportunities we are able to better equip for students the critical roles they will occupy in the future health care workforce.

**Climate versus Culture: Barriers to Influenza Vaccination among Nursing Home Staff**

Sarah Blake, Rollins School of Public Health of Emory University; Jessica Grosholz, PhD(candidate), Rollins School of Public Health, Emory University; Jill Daugherty, PhD, Rollins School of Public Health, Emory University; David Howard, PhD, Rollins School of Public Health, Emory University

**Presenter:** Sarah Blake, PhD, MA, Senior Associate, Department of Health Policy & Management, Rollins School of Public Health of Emory University, scblake@emory.edu

**Research Objective:** Seasonal influenza vaccination among nursing home staff has been shown to reduce the risk of flu among vaccinated adults and the risk of illness and death among nursing home residents. For over two decades, the U.S. Advisory Committee on Immunization Practices (ACIP) has recommended annual influenza vaccination of health care personnel. Yet according to a 2012 CDC report, fewer than 50% of health care staff working in long-term facilities received the flu vaccine. This study examined the policies and practices of nursing homes in three states (Florida, Georgia, Wisconsin) to ascertain potential facilitators and barriers to staff vaccination.

**Study Design:** The study used qualitative methods to explore staff flu vaccination policies and practices in nursing homes. Interviews were conducted with nursing home administrators and senior staff to learn about how flu vaccination is offered, delivered, and documented for health care staff.

**Population Studied:** Site visits were held with 39 nursing homes in three states (Florida, Georgia, Wisconsin). Interviews were conducted at each site with a range of informants (administrators, Directors of Nursing, infection control managers) who had knowledge and/or responsibility for overseeing staff flu vaccination.

**Principal Findings:** Findings reveal that nursing homes facilitate flu vaccination by offering the vaccines to staff free of charge and usually onsite. These facilities also all provide some type of outreach or education to staff about the need for flu vaccination. In addition, approximately 30% of nursing homes offer some type of incentive (e.g., gift card or cash) to promote flu vaccination among staff. Yet administrators report that staff vaccination rates remain low in most facilities (~50%). Staff refuse to be vaccinated due to a fear of getting sick, fear of needles, and overall lack of interest in the vaccine. Habit appears to play a major role as well, as many nursing home staff have never been vaccinated and do not feel they need it. Other barriers include: mistrust of the vaccine and fear “of the unknown.” Many nursing home workers are suspicious of the flu’s ingredients and hold culturally-based beliefs against vaccination. Interestingly, nursing home leaders also report low flu vaccination rates, particularly in Georgia and Florida, where only 50% of administrators and senior staff receive flu vaccination.

**Conclusions:** Despite the availability and accessibility of flu vaccination in nursing homes, staff vaccination rates among facilities in our study were low. Findings reveal that nursing home workers hold strong personal beliefs and bias against vaccination, including nursing home administrators and senior staff. Educational efforts to increase flu vaccination should be directed to all levels of nursing home staffing as well as leadership. Such efforts should clarify the public health benefits of flu vaccination as well as the risks of transmission to nursing home residents.

**Implications for Policy, Delivery, or Practice:** Increasing staff vaccination in nursing homes should be a priority for public health officials and managers of long-term care facilities. Our study
supports the need for improved education and outreach so that nursing home staff can overcome personal and cultural barriers to flu vaccination.

**Title VII Grant Programs’ Effect on Medical School Graduates’ Career Plans to Pursue Primary Care and Work with Underserved Populations**

Scott A. Shipman, M.D., M.P.H., AAMC Center for Workforce Studies; Shannon Bolon, Department of Health and Human Services; Karen C. Jones, M.Ap.Stat., AAMC Center for Workforce Studies; Shana F. Sandberg, Ph.D., AAMC Center for Workforce Studies; George A. Zangaro, Ph.D., R.N., DHHS/Health Resources and Services Administration; Shannon K. Bolon, M.D., M.P.H., DHHS/Health Resources and Services Administration

**Presenter:** Shannon Bolon, M.D., M.P.H., Primary Care Medical Education Branch Chief, Health Resources and Services Administration, Department of Health and Human Services, sbolon@hrsa.gov

**Research Objective:** To study the effect of medical school funding from Title VII grants on student career plans to pursue primary care and work with underserved populations.

**Study Design:** Data consisted of medical school-specific Title VII funding provided by HRSA combined with applicant, matriculant, and graduate medical student information from the AAMC. Each medical school was grouped by the amount of Title VII funding corresponding to the years that graduate cohort attended medical school. Generalized estimating equations were used to model students’ career plans at graduation for primary care specialty and work with underserved. Analyses were adjusted for covariates that included a more complete set of school and student characteristics than possible with previous related research and were stratified based on student interest in primary care at matriculation. Career plans at graduation were chosen as the outcome rather than eventual practice in order to isolate the impact of medical school-based Title VII funds from later subsequent training experiences that might influence career plans.

**Population Studied:** Students graduating from all allopathic U.S. medical schools between 2001 and 2004, n = 62,831. This period contains comprehensive information on student career plans at multiple points in time.

**Principal Findings:** As students were exposed to increasing levels of Title VII grant funding, there was a stepwise increase in the likelihood of a graduating student reporting plans to enter primary care. Students from schools in the highest quartile of funding were 26 percent more likely, 95CI= 1.05-1.46, than students at schools with no funding to indicate plans at graduation to practice primary care, while those at schools in the lowest quartile were 13 percent more likely, 95CI= 1.04-1.22. An increased interest in working with the underserved was found for those graduating students who attended schools in the highest quartile of funding, compared to those with no funding, those with an initial interest in primary care were more likely to sustain that interest, RR=1.26; 95CI= 1.05-1.46, while those who were initially undecided about their specialty interest were more likely to shift toward a planned career in primary care, RR=1.29; 95CI= 1.05-1.56.

**Conclusions:** After controlling for key covariates, Title VII grant funding to medical schools has had a sizeable positive impact on graduates’ plans to practice primary care and a modest positive influence on plans to work with underserved populations.

**Implications for Policy, Delivery, or Practice:**

The Public Health Service Act Title VII Section 747 grant program – celebrating its 40th anniversary in 2013 – represents an important effort to strengthen the primary care pipeline and produce more physicians for the underserved. In light of projected shortages of primary care physicians and those working with the underserved, this study highlights the successful effects of the Title VII grant program. Title VII funding to medical schools supports primary care as a career choice during medical school and also has a positive impact on students’ plans to work in underserved communities.

**Overview of Findings from the Longitudinal RNWORK study: Newly Licensed and Early Career Registered Nurses’ Turnover**

Carol Brewer, University of Buffalo, School of Nursing; Christine T. Kovner, PhD, RN, FAAN, College of Nursing, New York University
**Presenter:** Carol Brewer, Ph.D., R.N., FAAN, Associate Dean and Professor, School of Nursing, University of Buffalo, School of Nursing, csbrewer@buffalo.edu

**Research Objective:** The purpose of this presentation is to report longitudinal descriptive findings about nurses' work environment and predictors of turnover. We also will consider changes over time among newly licensed RNs (NLRNs) who have been followed from 2006 to 2011.

**Study Design:** The study design is a panel survey in which data were collected on the same sample of newly licensed registered nurses (NLRNs) early career nurses and two additional cross-sectional cohort surveys at five time periods 1-2 years apart. The conceptual framework is a model of turnover that incorporates nurses' demographics, work characteristics, organizational attributes and perceptions of the work environment and job opportunities.

**Population Studied:** The longitudinal sample is a nationally representative sample of recently licensed RNs from 34 states and the District of Columbia, who completed four waves of data collection immediately post initial licensure. A sample of 3370 RNs were enrolled in 2006 (Wave 1). Respondents to the initial survey were followed in 2007 (Wave 2, n=2,386), 2009 (Wave 3, n= 2,007), and 2011 (Wave 4, n= 1,544). The comparison cohort samples were from 14 states NC1 (n=1,765), and NC 2 (n=1,613).

**Principal Findings:** A majority of NLRNs experienced difficult months at their first job; some had already left their first job prior to the first survey. 17.3% had left their first nursing job within 1 year; but 54.5% had left within 6 years; most stayed in hospital nursing in subsequent jobs. They were satisfied with their work group but felt inadequate support from supervisors. Most of them reported having worked voluntary overtime, experiencing verbal abuse and physical injuries, and having inadequate supplies and equipment. RNs working in poor work environments experience higher physician abuse as well as more colleague abuse. As predicted by theory, turnover appears to be mediated by intent to stay: only if intent is removed from the regression does satisfaction and organizational commitment directly impact turnover. More sprains and strains and intent to stay directly increased turnover while working more voluntary overtime, holding more than one job for pay, reduced turnover. In multivariate analyses, organizational commitment is negatively influenced by mandatory overtime and low promotional opportunities. More variety and work group cohesion have a positive impact on satisfaction. During the economic downturn, RNs in the later cohort had higher commitment to their job though there were no changes in incomes and level of job satisfaction; NLRNs are also geographically immobile.

**Conclusions:** Solutions to turnover need to focus on predictors of satisfaction and organizational commitment.

**Implications for Policy, Delivery, or Practice:** Turnover problems are complex. Nurses tend to stay close to home so that local job opportunities impact choices. The work environment’s impact on the intent to stay and ultimately turnover underscores the need to create healthy work environments from nurses to keep them in their jobs, but over time keeping nurses in their first job is difficult. Better career advising by employers may keep nurses with the employer even if they change jobs internally.

**Twenty-Five Oral Health Workforce Innovations for Preventive Services**

Elizabeth Jacobs, ICF International; Karen Cheung, ICF International; Karen Cheung, ICF International; Michelle Revels, ICF International; Kari Cruz, ICF International; Mary Ann Hall, ICF International; Lisa Carver, ICF International; David Krol, Robert Wood Johnson Foundation

**Presenter:** Karen Cheung, M.P.H., Manager, Public Health and Survey Research, ICF International, karen.cheung@icfi.com

**Research Objective:** To describe the 25 innovations that participated in evaluability assessment site visits and discuss the findings related to programs’ potential impact in improving oral health, feasibility of implementation, and generalizability for a variety of settings.

**Study Design:** In 2012, as part of the Systematic Screening and Assessment of Oral Health Workforce Innovations project, researchers solicited nominations of promising workforce models and convened a panel of experts to review and select innovations for evaluability assessment (pre-evaluation) site visits. The purpose of these evaluability assessments was find innovations that were...
ready for evaluation and highly promising in terms of effectiveness, reach to the target population, feasibility, and generalizability. Between September-December 2012, trained site visitors conducted 3-day site visits to 25 innovations and workforce models that aimed to increase access to preventive oral health services. Prior to each visit, site visitors reviewed background documents and developed a preliminary logic model summarizing their understanding of the intervention design. During the site visit, the team used semi-structured guides to interview about 9-12 program staff members and stakeholders. During the last day of the site visit, EA site visitors facilitated a debriefing session with the program director and other key staff clarify their understanding of the program, refine the draft logic model, and discuss potential evaluation questions of interest.

**Population Studied:** Innovations implemented by dental providers in non-dental settings, non-dental providers in non-dental settings, and new types of dental professionals trained to provide preventive services.

**Principal Findings:** Dental providers may expand the public’s access to oral health services through a variety of programs and settings such as WIC clinics, Head Start programs, schools, mobile clinics, and senior centers. Non-dental providers, such as physicians, nurses, and nutritionists, can integrate oral health into their workflow and be trained to educate patients, perform dental screenings, and make referrals for dental treatment. New dental professionals who focus on preventive services may be added to the dental team, function independently in collaborative program with a dentist, or program under general supervision of a dentist. While some programs appear to be ready for evaluation, others may benefit from technical assistance in improving implementation practices.

**Conclusions:** Promising workforce innovations are being implemented across the country and have the potential to increase the capacity of dental and non-dental professionals in the provision of preventive oral health services.

**Implications for Policy, Delivery, or Practice:** These types of workforce interventions, programs, policies, and models strive to increase American’s access to oral health care, as well as prevent the onset of real diseases (e.g., tooth decay, gum disease, cavities).

**Funding Source(s):** RWJF

**Poster Session and Number:** A, #300

**Evaluation Opportunities of Oral Health Workforce Innovations**

Karen Cheung, ICF International; Karen Cheung, ICF International; Elizabeth Jacobs, ICF International; Kari Cruz, ICF International; Mary Ann Hall, ICF International; Lisa Carver, ICF International; David Krol, Robert Wood Johnson Foundation

**Research Objective:** To explore common existing data sources, data collection efforts, and outcome evaluation opportunities that may help demonstrate impact.

**Study Design:** As part of the Systematic Screening and Assessment of Oral Health Workforce Innovations project, a team of researchers conducted evaluability assessments (pre-evaluation site visits) to 25 innovations across the country. Two key products from these evaluability assessments included: (1) logic models that describe and link program resources and activities to outcomes and (2) potential evaluation questions and evaluation design options. Using the logic model as a tool and in collaboration with program staff, researchers derived suitable outcome evaluation questions.

**Population Studied:** Dental providers, non-dental providers, and new types of dental providers who expand the workforce to provide preventive oral health services for vulnerable populations, such as children, pregnant women, seniors, and Medicaid beneficiaries.

**Principal Findings:** A number of potential evaluation questions and designs for the 25 innovations participating in Systematic Screening and Assessment project were considered. There are a core set of research questions that help determine program effectiveness, such as: Which settings are most effective for reaching the target population? To what extent does the type of service provider impact the ability to reach the target population? To what extent does the program increase knowledge of and compliance with oral health recommendations among the target population? To what extent does participating in the program improve oral health outcomes, compared to those who do not participate in the program? To what extent does participating in the program...
increase linkage with a regular dental home? How does the program impact health disparities?

**Conclusions**: There is a need for further rigorous evaluation of oral health workforce innovations to assess their effectiveness in increasing access to and availability of preventive services—and ultimately, their effectiveness in improving oral health outcomes. Evaluation through direct data collection (e.g., parent and provider surveys and interviews) and existing data sources (e.g., claims data and dental records on diagnoses, treatments, and procedures) may answer questions about impact on oral health behaviors and outcomes.

**Implications for Policy, Delivery, or Practice**: Strong evidence of effectiveness comes from outcome evaluation studies that can meet high standards of rigor. More research is needed to develop this evidence base regarding the effective and efficient utilization of current health care workforce and their impact on access to preventive care and oral health outcomes. To create this evidence base, we must have a better understanding of the current interventions and practices being implemented and what works best.

**Funding Source(s)**: RWJF

**Poster Session and Number**: A, #301

---

**To What Extent Do Physician Assistants and Nurse Practitioners Provide Chronic Disease Primary Care?**

Bettie Coplan, Northern Arizona University; Joseph Benitez, MPH, School of Public Health, University of Illinois at Chicago; Richard Dehn, MPA, PA-C, College of Health and Human Services, Northern Arizona University; Roderick Hooker, PhD, PA, The George Washington University School of Public Health and Research

**Research Objective**: Physician assistants (PAs) and nurse practitioners (NPs) are increasingly employed to provide a broad range of medical services. However, despite their growing utilization, the extent to which NP/PA providers manage various medical conditions is not well known. As the population ages and the prevalence of chronic diseases grows, conditions such as hypertension, diabetes, and hyperlipidemia rank high among those for which care is needed. Therefore, the objective of this project was to determine the proportion of chronic disease services being provided by NP/PAs.

**Study Design**: All primary care patient visits from 2001-2010 were examined using the National Hospital Ambulatory Medical Care Survey (NHAMCS). Survey results were analyzed to estimate the total share of primary care visits by provider type and to identify differences in patient characteristics evaluated by each primary care provider.

**Population Studied**: The NHAMCS is a dataset of national samples of visits to outpatient departments of non-federal and non-institutional, general, and short-stay hospitals in the United States.

**Principal Findings**: The presence of NP/PAs represented in the NHAMCS almost doubled in this century. In the aggregate, NPs (8.9%) and PAs (5.4%) attended more than 14% of 777 million weighted visits, with NP/PAs managing 36% of visits in non-metropolitan areas. Over the latter five years, NP/PAs were the provider of record for one fifth of visits involving at least one chronic condition. For all three providers, the most common chronic disease visits were for diabetes and hypertension with similar percentages; 2% - 4% of visits to each provider type were for hypertension and 2% - 4% for diabetes. The only significant differences in patient characteristics resulted from sources of payment; NP/PAs were less likely to see patients with Medicare but more likely to see those with “no charge” than physicians. NPs were more represented in pediatrics, women’s health, and geriatric encounters than PAs. When examining non-metropolitan visits, hypertension was the most frequent of all diagnoses seen by physicians (3.4%) and PAs (5.4%) and the third most common diagnosis for NPs (3.9%). PAs were proportionately more represented than NPs in non-metropolitan clinics.

**Conclusions**: The proportional distribution of primary care chronic disease visits appears to be similar for PAs, NP, and physicians, with NP/PAs providing a significant proportion of care for patients in non-metropolitan areas.

**Implications for Policy, Delivery, or Practice**: We suggest that policies addressing chronic disease management strategies include NPs and PAs as deployable resources.

**Poster Session and Number**: A, #302
Early-Career Nurse Managers Report on Work Environment, Quality Improvement Education and Participation
Maja Djukic, New York University; Christine T. Kovner, PhD, RN, New York University College of Nursing; Carol S. Brewer, PhD, RN, Univeristy at Buffalo School of Nursing; Farida Fathehi, BS, MS, New York Univeristy College of Dentistry

Presenter: Maja Djukic, Ph.D., Assistant Professor, College of Nursing, New York University, md1359@nyu.edu

Research Objective: Front-line nurse managers can play a pivotal role in leading collaborative efforts to improve health care as recommended by the Institute of Medicine Future of Nursing Report, Key Recommendation #2. A knowledge gap exists on early-career nurse manager perceptions of health care environments in which they work and their education and participation in quality improvement (QI), which are key facilitators of health care improvement. We examined perceptions of work environments, QI education and participation in a national sample of early-career nurse managers to address this knowledge gap.

Study Design: We used a cross-sectional, descriptive design, and multiple data sources from an ongoing longitudinal study. QI data were collected in 2008 and work environment data in 2011 using a Dillman Tailored Design method mixed-mode survey. The research team used valid and reliable measures which were reviewed by a five-member expert panel and pilot tested. We examined responses to each survey question using descriptive statistics.

Population Studied: Registered nurses (RNs) initially licensed to practice between August 2004 and July 2005 from 34 U.S. states and D.C. were studied. We analyzed data from 42 RNs from the 2008 QI survey and 237 RNs from the 2011 work environment survey who reported being a nurse manager.

Principal Findings: With the exception of quantitative workload, nurse managers from the work environment survey reported generally positive ratings (defined as a mean rating above midpoint of each measurement scale) of job satisfaction, organizational commitment, intent to leave organization, workgroup cohesion, distributive and organizational justice, variety, autonomy, mentor support, collegial nurse-physician relations, promotional opportunities, and organizational constraints. In comparison to staff nurses, nurse managers reported significantly more autonomy and promotional opportunities. Less than a third of QI survey nurse managers reported being very prepared by their pre-licensure education programs and current employers across 12 measured QI activities such as data collection, analysis, measurement, flowcharting, and assessing gaps in practice. Only 9.5% reported being very prepared in using QI data analysis or project monitoring tools. Less than a third reported participating in any of the QI activities more than once monthly. More than half reported receiving zero hours of QI training from their employers. Specifically, 23.8% reported never participating in a root cause analysis, 81.0% reported no training in assessing gaps in practice, 61.9% reported no training in applying research evidence in practice, and 76.2% did not participate in web-based QI education, primarily because it was not offered.

Conclusions: Early-career nurse managers have positive perceptions of their work environments, but inadequate education and participation in QI. This represents a major barrier to taking on a leadership role in improving health care as recommended by the Institute of Medicine.

Implications for Policy, Delivery, or Practice: Employers and nursing education programs should work strategically to improve nurse manager education and participation in QI as a fresh approach to securing high quality patient care. Currently, no minimal education requirement policies exist for nurse managers. Developing such policies in conjunction with educational and organizational support might address the critical need to build nurse-manager leadership capacity to improve health outcomes at the front-lines of care delivery.

How Would Training Institutions Respond to a Reduction in Support for Graduate Medical Education?
Norman Edelman, State University of New York at Stony Brook; Mahrukh Riaz, Stony Brook University; Michael Yen, Stony Brook University

Presenter: Norman Edelman, M.D., Professor, School of Medicine, State University of New York at Stony Brook, norman.edelman@stonybrook.edu
Research Objective: All current federal budget proposals call for a reduction of support for graduate medical education [GME] by the Medicare program, some by as much as 33 percent of the total [Direct plus Indirect components]. The objective was to understand how training institutions might respond.

Study Design: Web based survey.

Population Studied: GME directors of all ACGME and AOA accredited non-federal general medical/surgical institutions.

Principal Findings: Of the 266 [51%] who responded, 20% of institutions with smaller programs [10 or less core residencies] and 31% of the larger [16 or more core residencies] indicated that a contingency plan for reduction of support had been developed. When asked the sequence of actions they would recommend if their institutions’ support for GME had to be reduced, the first steps of the larger programs focused on reduction of support for specific residencies while the smaller programs preferred across the board cuts. Eliminating a core program was a last choice by all; however a variety of subspecialty programs and the transitional year were frequently listed as potential choices for elimination.

To discern the value of core programs to the institutions, we asked respondents to rate the importance of programs to their institution both from an operational [and financial] point of view as well as a public service [and educational] point of view. Internal Medicine, Surgery and Emergency Medicine were ranked as “high” or “very high” from both points of view by 75% or more respondents. In contrast, Dermatology, Nuclear Medicine, Plastic Surgery and Preventive Medicine were ranked as “high” or “very high” by fewer than 35% of respondents from both points of view. Discordant responses were: Anesthesia and Neurosurgery [high operational, low public service] and Family Medicine and Psychiatry [high public service, low operational].

When asked which current GME governance policies generate unnecessary costs, most respondents cited restrictive work hour rules [57%] and excessive documentation requirements [47%]. Furthermore, when asked what changes in financing structure they would support as options to deal with a reduction of support from Medicare, the majority favored an all payer system [64%], movement to a non-Medicare based system such as that in place for Children’s Hospitals [53%], and if new funds are not available, restructuring of Direct GME reimbursement toward a single value per resident in order to increase the number of positions supported [52%].

Conclusions: We conclude that directors of GME are cognizant of a potential reduction of GME support by Medicare and are beginning to develop contingency plans. They would tend to preserve funding for core residencies over subspecialties and larger institutions would reduce support for specific core residencies rather than across the board. The broad range of perceived value of core programs may provide insight into which might be affected. At the national level, the majority would be willing to contemplate substantial changes in funding mechanism to preserve GME programs.

Implications for Policy, Delivery, or Practice: Residency training in areas not valued by institutions may be at risk for reduced support. Incentives for retaining those of public value such as Family Medicine and Preventive Medicine may be necessary.

Educating Future Physicians to Track Healthcare Quality: Feasibility of a Healthcare Quality Report Card for Medical Students

Donna Woods, PhD, EdM, Northwestern University; Daniel Evans, Northwestern University; Paul Jansson, BA, Northwestern University; Pietro Bortolotto, BS, Northwestern University; Sean O’Neill, PhD, Northwestern University; Erin Unger, MD, Northwestern University; Kristine Gleason, MPH, RPh, Northwestern University

Presenter: Daniel Evans, M.D., Assistant Professor, Department of Medicine, Northwestern University, devans@nmff.org

Research Objective: Background: The Patient-Centered Medical Home (PCMH) model aims to provide patient-centered care, lower costs, and improve health outcomes. In spite of the increased national emphasis on healthcare quality and outcome measurement, medical schools do not routinely provide educational opportunities for students to track quality measures or outcomes for patients.

Aim: To test the feasibility of a quality metric report card for medical students as part of a longitudinal Education-Centered Medical Home (ECMH) curriculum based on the PCMH model.
**Study Design:** We embedded teams of students in existing faculty practices and recruited a high-risk patient panel for each team, assigning students to be "health coaches" for 2-5 patients. From December 2012 through January 2013, students enrolled in the ECMH curriculum performed retrospective chart reviews and reported de-identified patient data on 20+ nationally endorsed Meaningful Use quality metrics.

**Population Studied:** Study population: 202 medical students (thirteen ECMH student-teams) across nine existing Chicago area primary care clinics.

**Principal Findings:** To date, 143 students submitted de-identified QI data (71% response rate) for at least one patient (315 patients total, mean of 2.2 submissions per student). Health conditions of the ECMH patient panel included: 66% abnormal body-mass index, 58% hypertension, 26% diabetes, 23% active smokers, 21% coronary artery disease, 9% moderate to severe asthma, 7% atrial fibrillation, and 5% systolic heart failure. Initial performance on quality measures ranged from a high of 93% adherence to beta-blockers and ACE-inhibitors in systolic heart failure to a low of 13% on documentation of dilated diabetic eye exams. Among the ECMH patient panel, 68 patients (22%) were admitted to a hospital in 2012 (132 total admissions) with 32 re-admissions at <30 days.

**Conclusions:** Creating a healthcare quality report card using nationally endorsed certified for Meaningful Use quality improvement (QI) metrics for a medical student patient panel is feasible. Interim analysis demonstrates that our student-teams have been successful in recruiting a high-risk patient pool and that there is significant variation in adherence to national QI metrics at baseline. For each of the QI metrics tracked we asked students to report end-of-year performance data from 2010, 2011 and 2012. Future research will use these three data points as a baseline to use statistical process improvement and prospectively track ECMH quality. Further study is needed to assess the educational impact of this QI tracking curriculum on medical student knowledge, attitudes and skills regarding QI objectives.

**Implications for Policy, Delivery, or Practice:** Evidence is mounting that the PCMH might deliver on the “Triple Aim” of patient-centered care, lower costs, and improved health outcomes. Our patients need coordinated care – and our medical trainees need an educational home in order to acquire the unique skills and attitudes necessary for PCMH transformation. As medical school educators, we need innovative, practical and sustainable curricula to make sure our students are prepared for practice in this setting. We need graduates prepared to measure the quality of their care, and capable of improving the system moving forward.

**Cost Analysis of Staffing Options for Inpatient Care**

Evan Fieldston, University of Pennsylvania
School of Medicine & CHOP; Joan Li, McKinsey & Company; Bo Huang, Wharton School, University of Pennsylvania

**Presenter:** Evan Fieldston, M.D., M.B.A., Assistant Professor, Pediatrics, University of Pennsylvania School of Medicine & CHOP, fieldston@email.chop.edu

**Research Objective:** Develop a financial model to compare the costs of various unit-level frontline ordering clinician (FLOC) staffing options and understand the role of graduate medical education (GME) funding on the costs of resident-trainees as FLOCs.

**Study Design:** Financial modeling of staffing cost for a hypothetical 20-bed pediatric unit under 4 coverage models: (1A,1B) intern/senior residents with attending supervision (1A: post- / 1B: pre-2003 ACGME duty-hour restriction); (2) hospitalist only; and (3) nurse practitioner (NP) & attending physician. Cost estimate based on effective annual compensation for inpatient time of clinicians only, accounting for number of employees, difference in resource utilization efficiency, and GME subsidy. Sensitivity analysis to obtain range of cost estimates with different mixes of full-time clinicians vs. rotating academic attendings.

**Population Studied:**

**Principal Findings:** The most expensive option is residents & attendings without GME subsidy ($1.42 million/year or $163/hour). The least expensive is NPs & attendings ($793,750/year or $91/hour). The duty-hour regulations increase costs significantly. One example of clinical resource inefficiency (e.g. extra testing) estimated at the 10% level also illustrates the costs of an institution of having trainees as FLOCs. Including GME funding reduces cost to
comparable levels with staffing either hospitalists or NP & attendings.

**Conclusions:** The cost of staffing an inpatient unit varies across a number of parameters, but trainees are not the obvious least expensive option. GME funding is important to offset the costs of trainee and supervisor staffing, especially with duty-hour rules.

**Implications for Policy, Delivery, or Practice:** Government subsidy of medical training via GME subsidy is important to maintain the public good of and prevent market failure in physician training.

**Patient Satisfaction is Lower in English Hospitals with More Imported Nurses**

Hayley Germack, University of Pennsylvania; Douglas M Sloane, School of Nursing, University of Pennsylvania; Anne Marie Rafferty, Florence Nightingale School of Nursing & Midwifery, Kings College London; Linda H Aiken, School of Nursing, University of Pennsylvania

**Presenter:** Hayley Germack, B.A. BSN, Hillman Scholar, Center for Health Outcomes and Policy Research Pre Doctoral Fellow, School of Nursing, University of Pennsylvania, germack@nursing.upenn.edu

**Research Objective:** England has long been reliant on imported nurses resulting in international controversy about brain drain from countries with few resources and great illness burden. While the ethics of international nurse recruitment has received much attention, there is little research on whether importing nurses affects quality of care in the host country. This study examines whether patient satisfaction with care in National Health Service (NHS) hospitals in England is associated with the proportions of imported nurses that work in them.

**Study Design:** This cross-sectional study used secondary data from the 2009 NHS Adult Inpatient Survey merged with the EU-funded study of nurses, RN4CAST, providing administrative and nurse survey data from the same period to investigate how hospitalized patients’ experiences were affected by the presence of imported nurses. Logistic regression models were estimated using Huber-White procedures to account for the clustering of patients in hospital trusts to determine whether the proportions of imported nurses were significantly related to patient experiences before and after taking account of other hospital and nursing characteristics and differences across hospitals in the characteristics of the patients surveyed.

**Population Studied:** The patients studied were 13,252 patients discharged from 46 hospitals in 31 NHS hospital trusts in England between June 1st and August 31st of 2009. All patients were 16 years or older, had at least one overnight stay, and were not under the care of a consultant from maternity or psychiatric specialties. The nurses studied were 2,928 professional nurses providing direct care on medical and surgical units in the same hospitals.

**Principal Findings:** Overall, 15% of the nurses in the study hospitals received their nursing education in countries with a developing economy (based on the World Economic Outlook classification of countries). The percentage of imported nurses ranged across hospitals from 0% to 41%, and had a significant and pronounced effect on patient experiences. Even after controlling for a sizable number of potential confounds, every 10% increase in the percentage of imported nurses lowered the likelihood (or odds) of patients reporting good or excellent care by roughly 19% (OR=0.81), and increased the odds on patients complaining about their care by about 19% (OR=1.19). Patient’s confidence in nurses and their satisfaction with nurse communication, staffing adequacy, and pain control were also lower in hospitals with higher percentages of FENs.

**Conclusions:** Patients in hospitals with higher proportions of imported nurses were significantly less satisfied with their care.

**Implications for Policy, Delivery, or Practice:** While imported nurses are commonly employed by first world countries with a developed economy in responding to nurse shortages, the experience of patients in English hospitals suggests that their use may have detrimental consequences for patient satisfaction. Further research should examine whether other quality of care outcomes are associated with substantial use of imported nurses. These findings provide additional motivation for national nursing workforce planning that prevents cyclical nursing shortages through greater reliance on domestically educated nurses.

Internationally Educated Nurses: Role of Market Factors in the Decision to Hire
Shivani Gupta, University of Alabama at Birmingham; Josue Patien Epane, University of Alabama at Birmingham; Dr. Robert Weech-Maldonado, University of Alabama at Birmingham

Presenter: Shivani Gupta, Graduate Reasearch Assistant, Administration-Health Services, University of Alabama at Birmingham, sgupta9@uab.edu

Research Objective: Although, the recent U.S. nursing shortage seems to have eased as many nurses returned to work due to the 2008 recession, it is projected that the demand for registered nurses will soon surpass their supply due to an aging population. Hospitals hire internationally educated nurses (IENs) as a strategy to address such shortages. The purpose of this study is to examine the impact of competition and other market factors, besides nursing shortage, on the hospital’s hiring decision.

Study Design: Data were derived from two sources: the American Hospital Association (AHA) Annual Survey and the Area Resources File (ARF). The dependent variable represents hiring decision (1 – did hire and 0 - did not hire). The primary independent variables include: competition measured by Herfindahl-Hirschman Index (HHI), states with certificate of need (CON), states with staffing mandate, population 65 years and older, percent of foreign born, percent of Blacks, Hispanics, Asian/Pacific Islanders, American Indians and others, supply of registered nurses per 1000 population, Medicare managed care penetration, unemployment rate, poverty, number of ambulatory centers, rurality, and regional location. Control variables include: diversity orientation (diversity plan), collection of patient’s primary language, ownership status, hospital size, system affiliation, teaching status, and proportion of Medicaid and Medicare patients. A panel logistic regression with facility random effects and year fixed effects was used for analysis.

Principal Findings: Results show that hospitals operating in markets with lower levels of competition (O.R = 0.57; p = 0.016) are less likely to hire IENs. In contrast, hospitals operating in areas with higher a percent of foreign-born (O.R = 1.06; p = 0.001), Blacks (O.R = 1.02; p = 0.001), Hispanics (O.R = 1.03; p = 0.001), and American Indians (O.R = 1.07; p = 0.001) are more likely to hire IENs. Similarly, hospitals in states with certificate of need (O.R = 1.87; p = 0.001) or staffing mandate (O.R = 2.18; p = 0.036) are more likely to hire them. Non-federal government hospitals are less likely to hire IENs compared to for-profit hospitals (O.R = 0.55; p = 0.014). Lastly, larger hospitals (OR= 1.00; p= 0.001) as well as those with a diversity orientation (O.R = 2.54; p = 0.001) and that collect patient’s primary language information (O.R = 1.47; p = 0.014) are more likely to hire IENs.

Conclusions: Results suggest that hospitals use IENs as a strategy to meet staffing needs in more competitive and diverse markets, and in states with staffing mandates.

Implications for Policy, Delivery, or Practice: The recruitment of IENs can have considerable impact on the quality of care and patient outcomes. Furthermore, IENs can alleviate the consequences of nursing shortages. Therefore, it is important to understand the various factors that may influence the recruitment and retention of IENs.

State Variation in Generalist and Specialty Physicians with Non-Physician Clinicians in Physician Offices, 2012
Esther Hing, National Center for Health Statistics; Chun-Ju Hsiao, National Center for Health Statistics

Presenter: Esther Hing, M.P.H., Survey Statistician, Ambulatory and Hospital Care Statistics Branch, National Center for Health Statistics, eshire2@cdc.gov

Research Objective: This study examines state variation in the percentage of generalist (general or family practice, internal medicine, pediatrics) and specialty physicians working with non-physician clinicians (nurse practitioners, physician assistants, and nurse midwives) in office-based practices.

Study Design: The 2012 National Electronic Health Record Survey, an annual nationally representative sample survey of nonfederal office-based physicians, was designed to produce state-level estimates. This study...
compares the percentage of generalist and specialty physicians working with non-physician clinicians. Estimates were weighted by the inverse of selection probabilities to make state and national estimates. State differences were evaluated by t-tests and multivariate analysis. Covariates examined included urban-rural classification of the practice location (large central metropolitan, large fringe metropolitan, medium of small metropolitan, non-metropolitan areas), practice size (1-2 physicians, 3-10 physicians, 11 or more physicians), multi-specialty practice status, percent revenue from Medicaid (above median, equal or below median, unknown), and state.

**Population Studied:** Generalist and specialty physicians reporting whether their practice had non-physician clinicians (n=4,430).

**Principal Findings:** There was no difference in the percentage of generalist (53%) and specialty physicians (55%) working with non-physician clinicians in 2012. Overall, the percentage of physicians working with non-physician clinicians was greater in practices located in small or medium metropolitan areas (60%) than in large central (51%) or large fringe metropolitan areas (49%), increased with size (from 33% among solo and partner practices to 80% among practices with 11 or more physicians), was higher in group single-specialty (58%) and group multi-specialty practices (77%) than solo practices (28%), and was higher in practices with percent of Medicaid revenue above the median (57%) than in practices with less Medicaid revenue (48%). The percentage of physicians working with non-physician clinicians varied by state. After controlling for location and practice characteristics, generalist physicians were more likely to work with non-physician clinicians in practices with 11 or more physicians compared with solo or partner practices, in multi-specialty practices compared with solo physicians, and outside of large central or large fringe metropolitan areas. Compared with generalist physicians in California, generalist physicians were more likely to work with non-physician clinicians in 15 states (Alaska, Arizona, Colorado, Idaho, Kansas, Massachusetts, Minnesota, Montana, New Hampshire, North Carolina, North Dakota, South Dakota, Tennessee, Vermont, and Wyoming). Comparable analysis among specialty physicians found lower use of non-physician clinicians in Connecticut and Hawaii compared with California specialty physicians.

**Conclusions:** In 2012, after controlling for location and practice characteristics, generalist physicians were more likely to work with non-physician clinicians in large practices, multi-specialty practices, in medium, small, or non-metropolitan areas, and in 15 states. After controlling for location and practice characteristics, there was little state variation among specialty physicians with non-physician clinicians in their practice.

**Implications for Policy, Delivery, or Practice:** State variation in generalist physician use of non-physician clinicians reflects, in part, higher use in rural states, and in states with higher percentages of large multi-specialty practices. Further research is needed to monitor the supply of generalists and their use of non-physician clinicians as provisions of the Patient Protection and Affordability Act expand Medicaid eligibility criteria in 2014.

---

**Estimate of Physician Supply and Distribution for Greater Tokyo in 2020**

Hiroo Ide, Chiba University; Hideaki Kawaguchi, The University of Tokyo; Soichi Koike, The University of Tokyo

**Presenter:** Hiroo Ide, Ph.D., M.A., Associate Professor, Research Division of Healthcare Policy in Aging Society, Chiba University, ide@chiba-u.jp

**Research Objective:** The population of Greater Tokyo was approximately 35 million in 2010 and is expected to remain the same in 2020. However, the population of the elderly (aged > 65 years) will increase by about 2 million and the proportion of them will rise from 21.0 % to 26.8%. Greater Tokyo is likely to remain the world's most densely populated area and demand for healthcare services for the elderly will increase.

**Study Design:** Retrospective database study

**Population Studied:** We used the data acquired from the official physician registry survey (Survey of Physicians, Dentists, and Pharmacists) in Japan. The number of physicians and information on sex, age, their specialty, and their working facilities were obtained from the registry data 1996–2010. We used the Bayesian theorem to estimate the numbers of physicians in all areas in Greater Tokyo. We calculated the numbers of physicians per 100,000 population and 100,000 elderly, and

**Principal Findings:** The total number of physicians is predicted to increase from 76,000 to 94,000 by 2020, equivalent to an increase in physicians per 100,000 population from 215.4 to 267.6. Although physicians per 100,000 elderly increased from 1,012.6 in 2000 to 1,048.3 in 2010, we expect the per capita supply to decrease to 997.9 by 2020. Internists in clinics administer primary care in Japan. We expect internists in clinics per 100,000 elderly will also decrease by 2020. We calculated Gini coefficients for all physicians per 100,000 population and per 100,000 elderly and found the inequity was almost stable. However, Gini coefficients for internists in clinics per 100,000 elderly will rise from 0.3265 in 2000 to 0.3959 in 2020.

**Conclusions:** Although the supply of physicians per capita in Greater Tokyo will increase, the number of physicians per 100,000 population is well below the average for Japan. Furthermore, physicians per 100,000 elderly and the equity of primary care distribution will decrease. These results imply access to healthcare services will become more difficult and may present a substantial problem for health care provision.

**Implications for Policy, Delivery, or Practice:**
The government estimates that by 2030, 27.9% of the population will be elderly. Unless steps are taken to ensure an adequate supply of physicians, access to and equity in healthcare services will worsen. Existing policies have encouraged physicians to practice in rural and remote areas. However, changes in the age structure and the distribution of urban populations indicate that more physicians are needed in urban areas that will appear throughout the world by the middle of this century. We suggest the existing physician distribution policy should change to provide for urban areas as well as for rural and remote areas.

**A Strategy for Enumerating the National Public Health Workforce, the Netherlands**

Marielle Jambroes, Academic Medical Center Amsterdam; Karin Stronks, Academic Medical Center Amsterdam; Marie-Louise Essink-Bot, Academic Medical Center Amsterdam

**Presenter:** Marielle Jambroes, M.D., M.P.H., Phd Student, Public Health, Academic Medical Center Amsterdam, m.jambroes@amc.nl

**Research Objective:** Insufficient insight in the size and composition of the public health workforce is an issue in many countries. We developed and tested an online questionnaire in order to enumerate the current national public health workforce capacity and project future needs.

**Study Design:** Based on international examples (e.g. USA, UK, WHO) of essential public health services, we defined ten essential public health services for the Netherlands, for example ‘Disease prevention and control’, ‘Development and evaluation of health policies’ and ‘Health promotion and social participation’. Subsequently we developed and tested an online questionnaire based on these essential services. The validity of the questionnaire was tested by interviewing respondents afterwards.

**Population Studied:** 580 employees of a medium-sized municipal health service were invited by e-mail to participate in the feasibility study. Participants were asked to indicate whether each of the essential services is part of their work and if so, the working time spent per essential service per week.

**Principal Findings:** Response was 217/580 (37%) with no significant differences in distribution by age and sex with the population that was invited to participate. 186 respondents (88%) indicated that at least one essential service was part of their work and 77 (37%) executed four or more. Most hours were spent on the essential service ‘Disease prevention and control’, the least hours were spent on ‘Assuring a competent workforce’. The distribution of educational levels within an essential service differed per essential service. For example 70% of the respondents involved in ‘Public health policy’ had an academic degree whereas of the respondents involved in ‘Health promotion’ 35% had an academic degree, suggesting that academic requirements differ per essential service.

The retrospective interviews showed that the individual estimation of the number of hours spent per essential services was the most difficult part of the questionnaire.

**Conclusions:** Our online questionnaire, based on essential public health services, is a good tool and strategy to enumerate the multidisciplinary public health workforce. The results of the feasibility study represent daily
practice and respondents appreciated the topic and the length of the questionnaire, although some questions were experienced as difficult to fill-out.

**Implications for Policy, Delivery, or Practice:**
We will now start implementing the tool on a national level because these data is essential to determining how to improve and maintain public health workforce competency and effectiveness.

**Interdisciplinary Teamwork and Nurse Autonomy: Are They Compatible and How Is Teamwork Associated with Nurse Outcomes**

Xiao Kang, University of Pennsylvania; Matthew D. McHugh, University of Pennsylvania, School of Nursing, Center For Health Outcomes And Policy Research

**Presenter:** Xiao Kang, B.A., B.S.N., Predoc, Center For Health Outcomes And Policy Research, University of Pennsylvania, kangxi@nursing.upenn.edu

**Research Objective:** The aim of the study was to examine whether interdisciplinary teamwork and autonomy were positively associated and determine the relationship between teamwork and nurse outcomes.

**Study Design:** A secondary analysis of the Multi-State Nursing Care and Patient Safety Study which collected data on characteristics of the hospital work environment and satisfaction with various aspects of the work environment from hospital nurses working in California, Pennsylvania, and New Jersey between September 2005 and August 2006 and in Florida between 2005 to 2006. Questions related to interdisciplinary teamwork and autonomy were aggregated to the hospital level to assess the relationships between these factors as well as the relationship between teamwork and nurse outcomes.

**Population Studied:** This study used a sample of 39,350 registered nurses from the Multi-State Nursing Care and Patient Safety Study. The nurses in this sample worked in 682 hospitals in California (n=13,176), Pennsylvania (n=9,973), New Jersey (n=8,381) and Florida (n=7,820). The sample includes at least 10 nurses per hospital.

**Principal Findings:** A strong association was found between teamwork and autonomy (r =0.87). When separated into categories of high (>75%), medium (25-75%) and low (<25%) levels of teamwork based on quartiles, nurses in hospitals with high levels of teamwork were significantly more likely than nurses in hospitals with low levels of teamwork to be satisfied with their jobs (mean = 0.85 vs. 0.70, p<0.001), satisfied with nursing as a career (mean = 0.91 vs. 0.83, p<0.001), less likely to leave their jobs (mean = 0.10 vs. 0.17, p<0.001) and had lower burnout scores (mean = 0.26 vs. 0.39, p<0.04).

**Conclusions:** Autonomy and teamwork are compatible characteristics of hospital work environments. Interdisciplinary teamwork was associated with better nurse outcomes.

**Implications for Policy, Delivery, or Practice:** Our findings support the Institute of Medicine’s recommendation promoting a team based approach to health care and interdisciplinary education as part of the preparation of the health care workforce. Hospitals should consider interventions that can promote both autonomy and interdisciplinary teamwork that can lead to better nurse outcomes.

**Determinants of Physician Practice Styles**

Herbert S. Wong, Agency for Healthcare Research and Quality; Zeynal Karaca, Social and Scientific Systems, Incorporated

**Presenter:** Zeynal Karaca, Ph.D., Health Economist, Center for Delivery, Organization, and Markets, Social and Scientific Systems, Incorporated, zeynal.karaca@ahrq.hhs.gov

**Research Objective:** Disparities in physician “practice styles” have emerged as a viable explanation for the substantial variations in medical treatment patterns across geographic regions. While this hypothesis enjoys a high degree of professional consensus, the specific factors that cause variation in the intensity of physicians’ use of medical resources are not well understood. This study identifies factors that influence physicians’ use of medical resources.

**Study Design:** We employed linear cost models using all hospital inpatient stays registered to physicians for whom we had information on observable characteristics. We also estimated multilevel regression models that clustered hospital inpatient visits across physicians. We repeated our linear regression analysis focusing separately on physicians working only in either teaching or non-teaching hospitals to address possible endogeneity of patient case mix and unobservable physician-specific factors.
that may not be completely addressed via regression models. Finally, we re-estimated our multilevel model using all hospital inpatient stays registered to two subsamples of physicians based on their observable characteristics by employing propensity score nearest-neighbor (NN) matching without replacement. The first subsample included equal numbers of male and female physicians with a similar distribution of observable characteristics. The second subsample included equal numbers of foreign trained and U.S.-trained physicians with similar observable characteristics.

Population Studied: We used the Healthcare Cost and Utilization Project (HCUP) State Inpatient Databases (SID), the American Hospital Association Annual Survey Database, and the Area Resource File in this analysis. Our hospital data for 2008 were drawn from Arizona and Florida, and physician information was obtained from medical boards of each state where we used physicians’ license numbers to register each hospital inpatient visit to a physician. Over 2.5 million inpatient records were used in the analysis.

Principal Findings: Our key findings remained the same across all estimations. Our risk-adjusted results show that the average cost of inpatient hospital visits registered to female physicians or foreign-trained physicians was significantly lower when compared to that of their respective cohorts. We observed an inverse relation between the average costs of hospital inpatient visits and physicians’ years of experience. We also found that physician practice specialty was an important source of variation in hospital inpatient costs, which were significantly higher for patients primarily treated by surgeons or cardiologists.

Conclusions: The key findings of our study indicate that: 1) the costs of hospital inpatient stays registered to female physicians or foreign-trained physicians are significantly lower than the costs of hospital stays registered to male physicians or U.S.-trained physicians; 2) the costs of hospital stays registered to physicians with more experience is lower when compared to physicians with less experience; and 3) there is substantial variation in costs of hospital inpatient stays across board certified physician specialties, where surgeons and cardiologists are generally associated with higher costs of hospital inpatient stays.

Implications for Policy, Delivery, or Practice: Our findings have important implications as they demonstrate that physicians’ characteristics have a significant impact on the costs of hospital inpatient stays.

Maryland Learning Collaborative Implementation of State Policy Using Educational Engagement of Primary Care Practices
Niharika Khanna, University of Maryland School of Medicine; Norman Poulsen, Johns Hopkins Community Physicians; Scott Feeser, Johns Hopkins Community Physicians; Sheila Richmeier, Remedy HC; Kathryn Montgomery, University of Maryland School of Nursing

Presenter: Niharika Khanna, MBBS, MD, DGO, Associate Professor, Family and Community Medicine, University of Maryland School of Medicine, nkhanna@som.umaryland.edu

Research Objective: The objectives of the Maryland Learning Collaborative (MLC) are to educate and engage primary care practices in Maryland to implement state policy, disseminate best practices and promote adoption of the Advanced Primary Care Model (APCM) and, to coach practices to transform into Patient Centered Medical Homes (PCMHs) recognized by NCQA and link PCMHs to health systems and community resources.

Study Design: We established the MLC as a state-academic partnership guided by the state’s medical schools, medical societies and PCMH practice champions to create a dynamic forum for development and implementation of the APCM. Year 1 featured: 1) Practice transformational activities by an expert coach with development of teamwork, leadership and care process redesign, culminating in recognition of PCMHs by NCQA; 2) developing collaborative peer learning forums utilizing live and multi-media methods; 3) supporting practices in interaction with state government and insurance carriers; 4) embedding PCMH care management; 5) practice workflow redesign for efficient, cost contained chronic disease management, population health and enhanced access to care; 6) optimizing EHR use; and 7) ensuring quality measures data was recorded in EHR fields that permit accurate data extraction.

Year 2 work includes: 1) quality improvement activities utilizing data reported by PCMHs benchmarked to the other MLC practices; 2)
adding a workforce training series with a didactic format for specific needs such as behavioral health training, Advanced Directives, and Medication Management; 3) linking PCMHs to community resources; 4) Pediatric Behavioral Health integration to enhance capacity to screen, manage and refer; 5) Partnership with Million Hearts; 6) ongoing practice transformation maintenance and care manager training; and 7) encouraging HIE linkage and utilization.

We evaluated the impact of MLC on primary care practices after one year of participation using an internet-based survey tool.

**Population Studied:** Statewide, 52 primary care practices, including 339 practitioners, make up our study population.

**Principal Findings:** Sixty-seven survey responses were analyzed. Of these, 49% were MD/DOs, 40% had 11-20 years in practice, 72% respondents were family physicians, and 68% were in a single specialty practice. The most important reasons for participating in the MLC were participation in the development of the APCM (45%) and readiness for healthcare reform (33%). After a year, MLC participants had a better understanding of the PCMH, improved job satisfaction, improved satisfaction with patient access to care, optimization of electronic health records, practice connectivity, care management, and medication management.

**Conclusions:** The MLC is an essential clinical component of the Maryland program in addition to administrative and technical components. MLC has successfully implemented the state’s policy to develop and implement an APCM and transform practices into PCMHs recognized by the NCQA.

**Implications for Policy, Delivery, or Practice:** A learning collaborative is an essential clinical component in state level programs to translate policy into implementation. PCMH Learning collaborative can provide the vehicle for integrating PCMHs into the Public Health Infrastructure, utilization of the Health Information Exchange and the Health Insurance Exchange to link newly insured patients to PCMHs.

**Dental Supply is Worse than You Think: Results from a Census of Georgia Dentists**
Glenn Landers, Georgia State University; Kristi Fuller

**Presenter:** Glenn Landers, Sc.D., M.B.A., M.H.A., Associate Project Director, Georgia Health Policy Center, Georgia State University, glanders@gsu.edu

**Research Objective:** To evaluate Georgia’s national dentist to population ranking and the availability of dentists serving Medicaid members.

**Study Design:** The study employed a mixed survey design. Subjects could respond by telephone, Internet, FAX, or through the U.S. mail.

**Population Studied:** All 5,881 dentists listed by the Georgia Secretary of State’s office as having an active dentist license as of March, 2012.

**Principal Findings:** Of the 5,881 dentists identified by the Georgia Secretary of State’s Office and the Georgia Dental Association, only 3,645 (61.5%) are in full or part-time practice in Georgia. Based on responses to this census, Georgia has 3.76 dentists per 10,000 residents. The most recent American Dental Association (ADA) ranking has Georgia at 4.4 dentists per 10,000 residents and a rank of 49. The state only has 885 dentists who accept Medicaid, and only four percent of those who do not are interested in becoming a Medicaid provider. Georgia has 16 counties without a dentist. Residents in these counties must travel approximately 18 miles or 29 minutes to the closest dentist in a neighboring county. Rational service areas are generally defined by 40 minutes of travel time to the nearest dentist or 25 miles under normal conditions on primary roads. Of the 16 counties without a dentist, 13 already have some type of dental health professional shortage area (DHPSA) designation, and the remaining three might qualify for single county designation based on their dentist-to-population ratios. Of the counties that already have some type of DHPSA designation, three appear to exceed the dentist-to-population ratio needed to qualify at least for single county designation. On the other hand, 28 counties without DHPSA designation might qualify based on low dentist-to-population ratios. FQHC and/or public health dental practices are located in some DHPSA designated counties, but many of them struggle financially.
Conclusions: State dentist licensing rolls may not be the most accurate measure of state dentist supply. It is from these rolls that organizations such as the American Dental Association, Kaiser State Health Facts, and the Centers for Disease Control and Prevention (CDC) create dentist to population ratios and national rankings. Such rolls may overinflate dentist supply by including dentists no longer practicing, practicing out of state, and practicing in environments not available to the general public, such as in dental schools and hospitals.

Implications for Policy, Delivery, or Practice: A short, standardized survey instrument completed upon license renewal could provide states with a more accurate picture of true dentist supply. Those states with below average dentist to population ratios might consider revision of scope of practice laws to allow dental assistants or therapists to expand the availability or oral health prevention and screening services. To improve the supply of dentists willing to serve Medicaid members, states might review reimbursement rates and policies aimed at patients keeping set appointments, a common complaint among those dentists who serve Medicaid members.

Insurance Coverage among Personal Care Aides in Residential Care Facilities
Bernie Lau, University of Washington

Presenter: Bernie Lau, M.P.H., Phd Student, Health Services, University of Washington, bernlau@uw.edu

Research Objective: As the American population ages, the demand for residential care facilities (RCFs), also known as assisted living facilities, is expected to grow. In this growing sector, demand for personal care aides (PCA) is predicted to increase almost 50% in the next decade. This expected growth in demand will provide new opportunities for employment for many low-skilled and semi-skilled workers; however concerns about ethical labor practices are emerging. Employment is an important source of health insurance coverage for many Americans, yet many lower-wage earners are not offered coverage or are unable to afford the premiums. As PCA develop as an occupation, the patterns of insurance coverage may be representative of coverage in other comparable fields.

Our study aims to estimate the proportion of RCFs offering health insurance coverage to PCAs and to test the association between offering insurance coverage and the RCFs’ financial certainty and demand for PCAs.

Study Design: We conducted a cross-sectional analysis of data from the 2010 National Survey of Residential Care Facilities. RCF financial certainty was approximated by three survey items: Medicaid revenue; occupancy rate; and not-for-profit status. Demand for PCAs was approximated by the hours of direct care provided by PCAs, the number of expected tasks performed by PCAs, and the use of substitutable labor such as volunteers and contractors. Logistic regressions were conducted to determine whether RCF financial certainty and PCA demand were associated with the offering of insurance coverage to PCAs. Regression models adjusted for facility size and staff composition.

Population Studied: The study population comprised 2,200 licensed RCFs with at least four beds and employing at least one full-time PCA.

Principal Findings: About 61% of surveyed RCFs provided some form of health insurance coverage to its PCAs; and among RCFs offering coverage to PCAs, about two-thirds provide at least 50% premium support. Adjusted regression analyses reveal most indicators of demand for PCAs were not significantly associated with insurance offering; although RCFs utilizing volunteers were more likely to offer insurance coverage (OR 1.44, 95% CI 1.13, 1.83). RCFs with high occupancy rate (OR 1.34, 95% CI 1.06, 1.70), owned by a chain (OR 3.65, 95% CI 2.88, 4.62), and employing more PCAs (OR 1.30, 95% CI 1.13, 1.49) were more likely to offer insurance. RCFs receiving Medicaid payments (OR 0.91, 95% CI 0.84, 0.98) and for-profit RCFs (OR 0.20, 95% CI 0.15, 0.28) were less likely to offer insurance.

Conclusions: These findings from a nationally representative sample indicate that a many RCFs offer insurance coverage to their PCA employees; however, this rate is lower than for the overall working population. Our analyses suggest the likelihood of insurance coverage may not be associated with indicators of demand for PCA labor. However, several factors related to financial security, as well as facility characteristics were associated with insurance offering.
**Implications for Policy, Delivery, or Practice:** Despite increasing demand for RCFs and PCAs, rates of insurance coverage are low compared to the overall working population. The ability and willingness to offer insurance coverage are likely associated with financial certainty of RCFs. In the face of impending employer mandates for coverage, changes in PCA employment dynamics may be expected; however, such changes may have consequences on the supply of RCFs as well as the quality of care provided.

**A Profile of Physician Medical Malpractice**

Doohee Lee, Marshall University; Charles E. Begley

**Presenter:** Doohee Lee, Ph.D., Associate Professor, Management, Marketing, MIS, Marshall University, leed@marshall.edu

**Research Objective:** While previous studies have examined various aspects of medical malpractice, the current literature lacks the information about physicians' perspectives of medical malpractice and their practicing behaviors at the national level. Therefore, we aim to answer the following research questions: Who are those physicians concerned about malpractice? Who are those physicians ordering more tests and consultations to avoid malpractice? Are any organizational and personal factors positively or negatively linked to the characteristics of physicians who concern about malpractices?

**Study Design:** This cross-sectional study simply documents the characteristics of physicians who concern about malpractices. Several statistical approaches were employed for this study including descriptive and inferential statistics for all variables. We also performed multivariate regression including the ordered probit model to test if personal and organizational factors remain significant in relation to malpractices. All of the data analysis was fully adjusted, using the weight variable given in the data and STATA `svy` commands, in order to represent a national sample and correct the complex survey design.

**Population Studied:** We analyzed secondary data, “the 2008 Health Tracking Physician Survey data (n=4,720)” collected by the Center for Studying Health System Change (HSC) and sponsored by the Robert Wood Johnson Foundation (RWJF).

**Principal Findings:** Regression results show that physicians who concern about malpractices are more likely to be male/older/IMGs/minority physicians; to report market competition. It is interesting to find physicians providing charity care are more likely to worry about malpractice. Finally physicians in Western states tend to concern about malpractice.

**Conclusions:** There is a great variation of physician characteristics in relation to medical malpractice.

**Implications for Policy, Delivery, or Practice:** Our study findings are based on physicians’ perspectives on medical malpractices. No prior study has investigated the characteristics of physician medical malpractices in relation to organizational and personal factors at the national level. More research is needed to understand how and the extent to which physicians strengthen or diminish their clinical ability in relation to medical malpractice.

**Improving Access to Dental Care through Diversity: The Data Disconnect**

Elizabeth Mertz, University of California, San Francisco; Cynthia Wides, UCSF Center for the Health Profession; Alexis Cooke, UCSF Center for the Health Professions

**Presenter:** Elizabeth Mertz, Ph.D., M.A., Assistant Professor, Preventive and Restorative Dental Sciences, University of California, San Francisco, elizabeth.mertz@ucsf.edu

**Research Objective:** The US seeks to improve the racial/ethnic and socioeconomic diversity of the dental workforce with the goal to improve access to oral health care for underserved populations. Yet most program evaluations fall short of linking recruitment, retention, practice patterns and patient outcomes. Building from the conceptual model of the “dental pipeline,” this study explores what data elements, methods, and operational steps are required to connect the chain.

**Study Design:** We conducted a systematic literature review in PubMed, Google Scholar, and Sociological Abstracts combining 20 keywords to identify programs to improve diversity, the stated rationales and goals, and reported outcomes. We examined publicly available data sources on the dental workforce, programmatic data where possible, and
assessed the linkages among them for longitudinal tracking over time.

**Population Studied:** Dental Students and Dentists

**Principal Findings:** Evidence presented to link diversity to patient access to oral health care consists primarily of racial concordance between patients and practitioners -- often not based on practice data but on geographic proximity. Metrics and data measuring ‘cultural competence’ and ‘access to care’ outcomes, cited as key goals for diversity programs, are lacking. Data linking dental student recruitment efforts to education exist but are generally not publicly available. Association data are available on education (admission, entry survey, exit survey, matriculation) and practice (state of license, practice location, practice populations and staffing), however, education and practice data are not linked restricting longitudinal tracking. Payment data (Medicaid, private insurance) tracks utilization, however health outcomes are only available from national population surveys.

**Conclusions:** A wealth of dental workforce data exists, however these data sources are disconnected or not publicly available, restricting meaningful analysis of the impact of diversity efforts within the “dental pipeline” on dental care access and health outcomes. Organizational policies pose a greater barrier to analytic progress in this area than do methodological issues.

**Implications for Policy, Delivery, or Practice:** Organizations which collect and maintain dental workforce data need to better collaborate with each other, as well make data available to workforce researchers if meaningful analysis on the dental pipeline is to made be possible. Policy analysis on the actual health care system outcomes of dental diversity and other pipeline efforts will not be possible without more transparency, linkages, and access to data on the dental workforce. **Interprofessional Collaboration and Identity Development at the VA Connecticut Healthcare System Center of Excellence in Primary Care Education: A Qualitative Analysis**

Emily Meyer, VA Connecticut Healthcare System; Rebecca Brienza, MD, MPH

**Presenter:** Emily Meyer, Ph.D., Research Coordinator, Center of Excellence in Primary Care Education, VA Connecticut Healthcare System, emily.meyer@va.gov

**Research Objective:** The primary objective of this research was to assess how internal medicine interns/residents and nurse practitioner (NP) fellows at the VA Connecticut Healthcare System (VACHS) Center of Excellence in Primary Care Education (CoEPCE) developed interprofessionally during their first academic year of training.

**Study Design:** Qualitative methods were used to assess how the first cohort of VACHS trainees changed not only individually, but also as a group. Three sets of semi-structured interviews were conducted at discrete data collection time points to assess individual and group growth (n = 20). Interviews were transcribed and uploaded into Atlas.ti 9.0. Implementing theoretically-grounded qualitative methods, we assessed how CoEPCE NP fellows and residents’ professional and team identities developed over the academic year. The data underwent three phases of reduction, which resulted in several distinct themes and sub-themes.

**Population Studied:** Our target population includes health care professionals currently engaged in post-graduate clinical training. The specific program under investigation, the VACHS CoEPCE, employs an innovative approach to post-graduate health professional education by training resident physicians and NP fellows to function effectively in teams and provide exceptional patient-centered team-based care. Based on four core domains of shared decision making, sustained relationships, performance improvement and interprofessional collaboration, the CoEPCE is one of the first national efforts to embrace an interprofessional training approach that directly addresses divergence in nursing and medical care models.

**Principal Findings:** Findings indicate that NP fellows and interns/residents entered the CoEPCE with a strong sense of self; however an understanding of how they complement other professionals in an educational and clinical environment was less apparent. Over time, both groups demonstrated increased understanding of others’ roles and were able to reflect on how differences/similarities informed interprofessional patient-centered care: “I just think it’s great to have the opportunity [to debate] issues and figure out how different people are...”
Evaluating State-Level Support-for-Service Programs Targeting Nurse Faculty

Jennifer Craft Morgan, Georgia State University; Marilyn H. Oermann, PhD, RN, FAAN, ANEF, University of North Carolina at Chapel Hill; Donald Pathman, MD, MPH, University of North Carolina at Chapel Hill; Mary R. Lynn, PhD, University of North Carolina at Chapel Hill; Thomas R. Konrad, PhD, University of North Carolina at Chapel Hill

Research Objective: State-level support for service (SFS) programs have been implemented by states to increase the numbers of nurses attracted into faculty positions in schools of nursing (recruitment), to enhance the qualifications and worklife of existing faculty, and to increase the retention of faculty in nursing programs. Most commonly, these are loan repayment, scholarship and loan cancellation/forgiveness programs in which an incentive is provided to a target group (e.g., graduate nursing students or currently active nurse faculty holding previous loans) if they teach in a nursing program within the state offering the support. The purpose of this paper is understand the perceived impact of these programs on recruitment and retention of nurse faculty from the perspective of deans and directors of nursing programs.

Study Design: Data are from a web-based survey of deans/directors of nursing programs (e.g., schools and departments) in eight states that have SFS programs (N=106; 46% response rate). All degree program types were included in the sample. Semi-structured interviews were conducted with a sub sample (N=27) of deans and directors and also with SFS program key informants (N=9). Interviews were transcribed, coded and a thematic analysis was conducted.

Population Studied: Deans and directors of nursing programs in community colleges and four year universities in eight states that have or have recently had a support-for-service program.

Principal Findings: About 70% of respondents indicate that they encourage faculty to use SFS programs to further their education. About 40% of deans and directors indicate they have hired faculty who have participated in a SFS program. Most deans and directors indicated that they believe that SFS programs have had some impact in their state in increasing the educational qualifications of current and newly hired faculty, retaining faculty, improving teaching quality, increasing the pool of qualified applicants and increasing the number of students their programs could enroll. More than half (64%) respond that the SFS program in their state helps to alleviate the nurse faculty shortage. However, relatively few use the programs explicitly as a recruitment or retention tool. Interview data will be used to contextualize the results. Factors that condition the severity of the shortage and the impact of the SFS programs include state-level, program-level and...
local labor market factors including the impact of the recent recession.

**Conclusions:** State-level SFS programs are perceived by deans/directors to have some impact on retention, capacity and recruitment pools for nurse faculty. The impact and effectiveness of these programs on nurse faculty recruitment and retention has been understudied. Phase two of the study will assess the impact of SFS programs on individual faculty participants.

**Implications for Policy, Delivery, or Practice:** This study highlights the need to understand the impact of SFS programs so that policymakers and program administrators can use scarce dollars to target SFS program use in contexts (e.g., type of degree program, faculty appointment type, labor market context) where they appear to have the greatest impact.

**The Changing Landscape of Nursing Education Programs: A Factor in the Surge of the Number of Young RNs?**

Douglas Staiger, Dartmouth University; Ulrike Muench, Vanderbilt University; David Auerbach, RAND; Peter Buerhaus, Vanderbilt University

**Presenter:** Ulrike Muench, Ph.D., M.S.N., Postdoctoral Fellow, School of Nursing, Vanderbilt University, ulrike.muench@vanderbilt.edu

**Research Objective:** Projections of an unprecedented nursing shortage to hit the US by 2020 have recently been updated by evidence suggesting a sudden increase in the numbers of registered nurses (RNs). While this was partially driven by the recession, research shows a dramatic surge in the number of young RNs, particularly RNs under the age of twenty-five. This is surprising, given the widespread concern about insufficient capacity of RN programs. In this study we examine whether this unexpected surge in young RNs may be driven by growth in nursing education programs.

**Study Design:** We conduct secondary descriptive analysis of data from the Integrated Postsecondary Education Data System (IPDS) of the 2000-2010 survey years. This survey collects institution-level data from US postsecondary institutions and includes data on types of degrees conferred, number of students enrolled, graduation rates and other institutional and demographic characteristics.

**Population Studied:** We study associate and baccalaureate degree RN graduates of the years 2000 through 2010.

**Principal Findings:** The total absolute growth of nursing degrees was 80,267 (104%), with relatively even absolute growth of 40,511 for baccalaureate (117%) and 39,756 associate degree programs (94%). All school types, i.e. public, private (not-for-profit), and private (for-profit), experienced growth. Private (for-profit) schools had the most significant growth of 2162% (515 programs in 2000 versus 11,649 programs in 2010), compared to 109% of private (not-for-profit) (17,676 programs in 2000 versus 369115 programs in 2010), and 85% growth of public programs (58,695 programs in 2000 versus 61,260 programs in 2010). Growth was observed for both men (140%) and women (100%), and across ethnicities, particularly for Hispanics (187%) and for other non-whites (263%). There was considerable variation in geographic growth by states, with states in the West and Midwest experiencing greater growth.

**Conclusions:** From 2000 to 2010, there was strong growth in the number of associate and baccalaureate degree RN graduates across a wide range of demographic groups and types of schools. Tremendous growth was observed in degrees from proprietary education programs.

**Implications for Policy, Delivery, or Practice:** Our findings suggest that increased demand in nursing education programs let to growth in this sector of education, producing workforce recruits rapidly, and easing concerns about a looming nursing shortage. While this is good news, there are concerns about the effects this may have on patient care and the delivery of health care services in the long term: First, the quality of RNs may have fallen as a result of an increase in 2-year college degrees. Second, evidence of an emerging surplus appears to surface. This may signal a discouraging outlook to the new generation of potential nurses, and could turn jobseekers to other professions, despite the continuing increased demand for nurses in the long-term given the demographic changes of the population.

Leveraging Worksite Health Promotion to Achieve Health-Risk Reduction, Lower Health-Related Spending, and a More Productive U.S. Health Care Workforce: Insights from the UPMC MyHealth Program

Michael Parkinson, UPMC Center for High-Value Health Care; Pamela Peele, PhD, UPMC Center for High-Value Health Care; Donna Keyser, PhD, MBA, UPMC Center for High-Value Health Care

Presenter: Michael Parkinson, M.D., M.P.H., Senior Medical Director, Health And Productivity, UPMC Center for High-Value Health Care, parkinsonmd@upmc.edu

Research Objective: To examine changes over time in the health-risk profile, individual lifestyle risk prevalence, preventive service use, and medical/pharmacy and productivity costs of a large health care workforce participating in a group health incentivized benefit plan incorporating a comprehensive wellness and health management program.

Study Design: This four-year, quasi-experimental cohort study of 15,510 UPMC health care employees participating in the UPMC MyHealth worksite health promotion program uses the Edington University of Michigan Health Research Center health-risk framework and a proprietary stratification model to identify an employee’s risk factors, categorize the population into low-, moderate-, and high-risk groups, and track movement between risk levels from 2007 to 2011. Changes in health risk, preventive service use, and cost outcomes for the entire cohort, as well as subgroups with targeted chronic conditions and modifiable lifestyle risks, are evaluated using McNemar, Chi-Square, and Paired-T statistics and available claims data from a statistically-matched control group.

Population Studied: The study cohort comprises group health-insured UPMC employees who completed a Health Risk Assessment as part of the UPMC MyHealth program and were continuously enrolled between 2007 and 2011. In 2011, cohort members were 49 years old on average and 77.6 percent female with the highest proportions employed as nurses (22.1 percent) or administrative support staff (20.1 percent).

Principal Findings: Significant health-risk improvements and associated positive-cost trending was observed for the entire cohort as well as specific subgroups. Between 2007 and 2011, the proportion of cohort members at low health risk increased significantly, 89.2 percent of members improved or maintained their health-risk status, significant improvements were observed in individual lifestyle risk prevalence, and medical/pharmacy and productivity costs decreased for members with improved risk status and increased for those with worsened risk status. Significantly higher use of preventive services and lower average medical/pharmacy costs were observed for the cohort in comparison with the control group. Among cohort members with diabetes, hypertension, or low back pain, percentages at low and high health risk increased and decreased respectively. Positive trending in medical/pharmacy and productivity costs was observed for cohort members who improved BMI and physical activity, reduced stress, and quit smoking in comparison with those who did not.

Conclusions: Continuous, high levels of participation in incentivized, comprehensive worksite health promotion programs, particularly when incorporated into health insurance benefit design, can improve the health-risk profile and individual lifestyle risk prevalence of the health care workforce leading to reduced health-related costs for the entire population as well as subgroups with specific chronic conditions and modifiable lifestyle risk factors.

Implications for Policy, Delivery, or Practice: Key provisions of the Affordable Care Act encourage employers to adopt and significantly financially incentivize wellness programs in order to improve the overall health status of Americans and control health care spending. Our findings suggest that the health care industry can benefit from these provisions as it works to improve the relatively poor health-risk status and high risk-adjusted service utilization of the U.S. health care workforce, constrain or reduce rising health-related costs, and enhance the productivity of this prominent and growing sector of the U.S. economy.

Family Medicine Rural Training Tracks: Graduate Early Career Outcomes

Davis Patterson, University of Washington; Randall Longenecker, MD, Ohio University Heritage College of Osteopathic Medicine; David Schmitz, MD, Family Medicine Residency of Idaho; Robert L. Phillips, Jr., MD, MSPH, American Board of Family Medicine; Susan M.
Research Objective: The proportion of matriculating medical students in 2011 reporting they intended to practice in a small town or rural area in 2011 was just 2.7 percent. The 1-2 model of family medicine rural training track (RTT) residencies combines one year of urban training with two years of rural training to address a well-documented shortage of rural providers, expected to worsen with insurance coverage expansion under the Affordable Care Act (ACA). The RTT Technical Assistance Program (RTT TAP), funded by HRSA’s Office of Rural Health Policy, aims to sustain, expand, and assess the outcomes of 1-2 RTTs. The last national evaluation of RTTs occurred more than 10 years ago. This study uses new data to determine the early-career outcomes of RTT program graduates in choosing to provide care to rural and underserved populations.

Study Design: Residency graduate identifiers, including National Provider Identifier numbers, were matched to post-graduate practice information in several sources, including the American Medical Association (AMA) Masterfile, Centers for Medicare and Medicaid Services (CMS) claims data (2009), and American Board of Family Medicine data. Graduates were tracked longitudinally from graduation for up to three years post graduation (depending on how recently they graduated) to determine their practice locations (urban/rural as defined by Rural-Urban Commuting Area codes; Health Professionals Shortage Areas (HPSAs)) and facility types (Federally Qualified Health Centers (FQHCs), Rural Health Clinics (RHCs), Critical Access Hospitals (CAHs)).

Population Studied: The RTT TAP collected data on 123 RTT graduates, in the academic years 2008-9 through 2011-12, from 18 of 25 RTT programs graduating residents during the period.

Principal Findings: Compared with family medicine residents overall, RTT graduates were more often male (54 percent), international medical graduates (51 percent), and older (by about 4 years). Of graduates from 2007-8 through 2009-10, 81 percent had achieved board certification as of 2011. Using AMA data, 49.4 percent of RTT graduates in clinical practice were in rural locations at graduation, declining slightly to 44.8 percent three years post-graduation. In contrast, using data from RTT programs, 71.9 percent of clinically active graduates began practice at graduation in rural areas. At graduation, 41.8 percent practiced in HPSAs, declining to 27.6 percent three years post graduation. Of those graduating in 2007-8 and 2008-9, nearly half (48.1 percent) were practicing in safety net facilities in 2009, mostly RHCs and CAHs but also FQHCs.

Conclusions: Depending on the data source analyzed, RTT graduates were approximately two to three times more likely than all family medicine graduates to practice in rural areas. High proportions practiced in HPSAs and safety net facilities. These findings suggest that RTT programs have succeeded in recruiting and preparing family physicians for practice with rural and underserved populations.

Implications for Policy, Delivery, or Practice: Increasing healthcare demand under the ACA highlights the urgency to identify and support effective strategies to ensure a sufficient primary care workforce. Policy and programmatic options to support the RTT model include new funding mechanisms; collaborations with FQHCs, RHCs, and CAHs to create new RTTs; technical assistance; human resource development; sharing of best practices; and augmentation of data to inform performance improvement and policy.

Funding Source(s): HRSA

Poster Session and Number: A, #325

Elena Platonova, University of North Carolina at Charlotte; S. Robert Hernandez, University of Alabama at Birmingham

Presenter: Elena Platonova, Ph.D., MHA, Assistant Professor Of Healthcare Management, Public Health Sciences, University of North Carolina at Charlotte, eplatono@uncc.edu

Research Objective: To examine the extent to which innovative human resource (HR) practices were used in a national sample of US hospitals. The study also assessed the extent to which HR management strategies were included in the organizational strategic planning process and the association between the inclusion and
involvement of senior HR professionals in corporate or business unit strategic planning with the use of innovative HR practices.

**Study Design:** An HR survey was developed and pretested. The Survey requested information on innovative HR practices in the following domains: human resource management (HRM) strategic planning, design of work systems, staffing methods, performance evaluation and compensation, employee training and development. The Survey also asked about senior HR professionals’ involvement in strategic planning and inclusion of HR strategies in organizational strategic planning. Frequency distributions were used to describe innovative HR practices in the sampled hospitals. Then, an HRM strategic involvement score for each hospital was calculated. Based on the score, all sampled hospitals were divided into a high or low HRM strategic involvement group. Binary logistic regression analysis was conducted to determine whether HRM involvement was associated with the use of innovative HRM strategies in the hospitals.

**Population Studied:** The Survey was administered to chief executive officers and HR executives from 85 hospitals across the United States in 2005. Respondents from 48 hospitals (56% of the contacted hospitals) completed the Survey.

**Principal Findings:** The most frequently used innovative HR practices were a customer focus orientation (mean 3.99 on a 5-point scale), innovative staffing methods (mean 3.81), and employee training and development (mean 3.36). The least used innovative HR practices were team-based pay plans, team-based compensation based on results, and job rotation strategies (means 1.9, 2.03, and 2.16, respectively). We found significant associations between HRM strategy inclusion in the strategic planning process and senior HR professionals’ involvement in organizational strategic planning and three innovative HR practices. Specifically, hospitals with high HRM involvement were about five times as likely as other hospitals to find talent in advance for key job openings (odds ratio (OR)=4.61, 95% CI: 1.10-7.38). Similarly, hospitals with high HRM involvement were about four times as likely to stress organizational culture and values in the selection process (OR=3.97, 95% CI: 1.01-3.97). Finally, hospitals that included HR strategies in the strategic planning process and involved their senior HR professionals in organizational or unit strategic planning were about six times as likely to base individual or team compensation on goal oriented results (OR=6.17, 95% CI: 1.17-3.37).

**Conclusions:** Our HRM data clearly indicate that innovative HR practices are still underused in some US hospitals despite their good potential to improve overall hospital performance. The means were far below 4.0 (on the 5-point scale) for the most innovative HR approaches.

**Implications for Policy, Delivery, or Practice:** We recommend that top hospital administrators should involve senior HR executives more extensively in the organization strategic planning process, incorporate strategic HRM practices in organization or unit business strategy, and increase the use of innovative HR practices in their organizations.

**Nurse Practitioners as Primary Care Providers: Practice Environments and Outcomes in Two States with Varying Scope of Practice Regulations**

Lusine Poghosyan, Columbia University; Carolyn Sun, MSN, ANP-BC, RN, Columbia University School of Nursing; Samantha Brown-Stonbraker, MPH, Columbia University School of Nursing

**Presenters:** Lusine Poghosyan, Ph.D., M.P.H., R.N., Assistant Professor, School of Nursing, Columbia University, lp2475@columbia.edu

**Research Objective:** The purpose of this study was to investigate practice environments for primary care nurse practitioners (NP) and the impact of practice environments on NP job satisfaction and turnover in Massachusetts (MA) and New York (NY).

**Study Design:** Cross-sectional survey design. Data were collected through mail (in MA) and online (in NY) surveys in 2012, using the Nurse Practitioner Primary Care Organizational Climate Questionnaire (NP-PCOCQ), measures of job satisfaction, turnover, demographics, and work characteristics. NP-PCOCQ measures practice environments in terms of NP-physician relations, NP-administration relations, support and resources, role visibility, and autonomy. In MA, surveys were mailed to 807 NPs recruited from the Massachusetts Provider Database; In NY, members of the New York Nurse Practitioner Association were emailed the link to our online survey. In MA, 298 NPs and in NY,
278 NPs completed the survey. Multiple logistic regression models were used to test the relationship between practice environments and NP outcomes. Models were controlled for NP demographics and work characteristics including years employed in the position, hours worked, and state (a dummy variable).

**Population Studied:** 576 primary care NPs participated. The mean age was 50 and 6.2% were male. Respondents practiced in a variety of care settings including physician offices, community health centers, hospital-based clinics, etc.

**Principal Findings:** 86% perceived that NPs and physicians practice as a team. Physicians in MA were more likely to ask NPs for suggestions (81.8% versus 72.0%, p=.005), and collaborate with them (95.4% versus 90.3%, p=.016). Of 576 NPs, 20% reported not receiving the same support for care management as physicians and 23% reported inadequate staff support to prepare patients for visits. In MA, NPs were more likely to have staff support than in NY (84.3% versus 69.6%, p<.001). As perceived by NPs (58.1%), administrations did not treat NPs and physicians equally or share information equally (43.6%). In NY, more NPs were dissatisfied with their jobs than in MA (30.2% versus 22.5%, p=.027) and reported intentions to leave their current job (19.4% versus 10.2%, p=.002). Controlling for NP and work characteristics, NP practice environments were associated with job satisfaction and NP turnover. The odds of job satisfaction increased 2.8 times with every unit increase in the scores of role visibility subscale. The odds of turnover decreased 2 times with every unit increase on the NP-physician relations subscale score.

**Conclusions:** In both states, there are deficiencies in NP practice environments. Favorable working relations with administration and physicians, access to necessary support, and clear visibility of NP role are important for successful NP practice.

**Implications for Policy, Delivery, or Practice:** This evidence will help organizations to design effective practice environments that will facilitate the optimal practice of NPs as primary care providers and promote their ability to deliver high quality care. The findings support the Institute of Medicine’s recommendation to expand the NP workforce in primary care settings by creating practice environments that minimize NP turnover and maximize job satisfaction. Maintaining a functional NP workforce is necessary to meet the increased demand for primary care during the implementation of health reform.

**Self-Reported Burnout among Primary Care Employees within the VA’s Patient-Aligned Care Team**

Joseph Simonetti, University of Washington Medical Center; Christian Helfrich, Health Services Research and Development, Department for Veterans Affairs; Emily Dolan, Office of Analytics and Business Intelligence, Department for Veterans Affairs; David Mohr, Center for Organization, Leadership and Management Research, Department for Veterans Affairs; Richard Stark, Primary Care Program Office, Department for Veterans Affairs; Gordon Schectman, Primary Care Program Office, Department for Veterans Affairs; Stephan Fihn, Division of General Internal Medicine, Department of Medicine, University of Washington, Seattle, WA; Health Services Research and Development, Department for Veterans Affairs; Kari Nelson, Division of General Internal Medicine, Department of Medicine, University of Washington, Seattle, WA; Health Services Research and Development, Department for Veterans Affairs; General Medicine Service line, VA Puget Sound

**Presenter:** Joseph Simonetti, Fellow, Division of General Internal Medicine, Department of Medicine, University of Washington Medical Center, simonja@uw.edu

**Research Objective:** In April 2010, the Veterans Health Administration launched a nationwide Patient-Centered Medical Home initiative called the Patient-Aligned Care Team (PACT). We assessed reported burnout among primary care employees approximately 2 years later and compared assessments using 2 different burnout measures. We also compared reported burnout among employees working in VA primary care with reported burnout in non-primary care settings using a national employee survey.

**Study Design:** A web-based PACT survey was administered in May 2012 to employees in primary care settings, including primary care providers (PCPs), nurses, clinical associates (e.g., LPNs) and clerical assistants. We used 2 measures of burnout: A 9-item version of the Maslach Burnout Inventory (MBI) which...
measures 3 sub-scales (emotional exhaustion, cynicism, and professional efficacy) using a 7-point Likert scale (sub-scale range 3-21). We also used a single-item measure from the Physician Worklife Study which asks respondents to classify their level of burnout using a 5-item scale (1=no burnout, 3=definitely burning out, 5=completely burned out). We defined respondents as having burnout based on a high score (>=9.5) on the emotional exhaustion sub-scale of the MBI or a score of >=2 on the single-item measure. We compared PACT findings to the 2012 VA All Employee Survey (AES), an annual survey administered to all VA employees (n=255,931, 62 percent response rate) that included the single-item burnout measure.

**Population Studied:** VA primary care employees.

**Principal Findings:** The PACT survey was completed by 6,467 employees (approx. 30 percent response rate); 27 percent were PCPs, 21 percent were clinical associates, 18 percent were nurse care managers, 9 percent were registered nurses (other than nurse care managers), 9 percent were clerical assistants and 16 percent were employed in another position. Based on the MBI, rates of self-reported burnout were highest for PCPs (48.5 percent) and nurse care managers (41.2 percent), followed by clerical assistants (36.8 percent), registered nurses (33.8 percent) and clinical associates (30.4 percent). Burnout rates, as measured by the single-item instrument, were similar to results from their MBI emotional exhaustion scale across all employee categories. A similar pattern of burnout among occupational groups was observed among Primary Care respondents to the AES; though burnout rates were 2-5 percent lower, on average, by occupation. Burnout rates were similar between AES respondents in Primary Care and AES respondents overall, except for providers, where PCPs reported a 40.3 percent burnout rate compared to 28.1 percent for VA providers overall.

**Conclusions:** Self-reported burnout among VA primary care employees was high, particularly among PCPs and nurse care managers. Estimates of burnout were very similar between two different burnout instruments and two different survey cohorts.

**Implications for Policy, Delivery, or Practice:** Burnout has been linked to employee turnover and quality of care, and may affect the ability of VA providers to address the primary care needs of Veterans nationally. This study demonstrates that we can reliably assess burnout in VA primary care settings, and is an important first step in assessing the association of PACT implementation with rates of employee burnout.

**Outpatient Productivity and Practice Characteristics of Rural Primary Care Nurse Practitioners in States with Varying Physician Oversight Regulations**

Susan Skillman, University of Washington; Louise Kaplan, PhD, ARNP, Nursing Program, St Martins University; C. Holly A. Andrilla, M.S., University of Washington Rural Health Research Center; Mark P. Doescher, MD, MSPH, University of Oklahoma

**Presenter:** Susan Skillman, M.S., Deputy Director, Center for Health Workforce Studies, University of Washington, skillman@uw.edu

**Research Objective:** Nurse practitioners (NPs) are a growing segment of the rural primary care workforce, yet little is known about how physician oversight requirements are related to rural NP practice characteristics or outpatient productivity. NPs’ roles are likely to grow even more important as the rural physician workforce struggles to meet demand. Limitations to NP practice autonomy, however, may impede NPs’ ability to meet the primary care needs of rural communities. This study examines outpatient productivity and practice characteristics of NPs in rural primary care settings across states with varying requirements for physician involvement.

**Study Design:** This mail/web cross sectional survey conducted in 2011 drew from a representative sample of NPs with rural mailing addresses (determined using Rural-Urban Commuting Area codes) in 13 states representing all Census regions. The sample (response rate 40%) included 745 NPs after excluding those not principally engaged in rural primary care. Each state’s NP practice regulations were categorized to explore whether productivity and practice patterns varied by degree of NP practice autonomy. Six states authorized fully autonomous NP practice, 5 required physician supervision and 2 required physician collaboration.

**Population Studied:** NPs practicing rural primary care in 13 states.

**Principal Findings:** Across all states, most rural practicing NPs worked in private practice (33.6
percent), federally qualified Rural Health Clinics (23.4 percent), and federally qualified community health centers (11.9 percent). Two thirds (66.7 percent) reported a practice specialty of family health, followed by women’s health (10.4 percent), adult health (9.3 percent), and pediatrics (9.1 percent). NPs in autonomous states reported similar average weekly hours in rural direct patient care as those in physician collaboration or supervision states (33.4, 35.1, 35.3, respectively; p=0.081) but fewer average total visits per week (54.9 vs. 71.2 vs. 66.6; p=0.000). NPs in autonomous states provided slightly fewer average weekly prenatal care visits (1.4, 2.6, 2.1; p=0.303) and more minor procedures (5.1, 4.6, 4.7; p=0.770) than in other states but the differences were not statistically significant. NPs in autonomous states provided fewer average weekly well child visits (5.3, 8.0, 7.9; p=0.012) compared with NPs in the other states. Most (83.6 percent) rural primary care NPs in autonomous states practiced with at least one physician, fewer than NPs in physician collaboration (86.8 percent) or supervision states (91.0 percent) (p=0.039). Approximately three quarters (73.8 percent) of all rural primary care NPs practice with other NPs, 31.9 percent practice with at least one physician assistant, and 6.0 percent practice with at least one midwife.

Conclusions: Rural NP productivity varies depending on state practice regulations. Further research is needed to identify the underlying reasons for the differences observed by this study and the patient care outcomes associated with varying NP practice models. For example, in autonomous practice states NPs may have more chronically ill and complex patients requiring longer visits than in states where physician supervision or collaboration is required. In autonomous states NPs may be involved in more administration which decreases productivity.

Implications for Policy, Delivery, or Practice: Estimates of the number of NPs required to meet rural population needs should consider the potential impact of state physician oversight requirements.

Rural Access to Primary Care: Evaluating the Quality of Research and Health Care Work Force Solutions
Johanna Steenrod, University of Pittsburgh; Alla G. Khadka, University of Pittsburgh; Abigail Stark, University of Pittsburgh

Research Objective: The United States continues to struggle with achieving equitable access to primary care for its rural citizens. Local, state and federal agencies as well as researchers and practitioners are working to address this issue through a number of intervention and policy avenues, particularly related to workforce training, distribution, and diversification; however, a sustainable solution has been slow to formulate. We model the knowledge production system to understand which authors, sources, and professions are the top influencers of knowledge creation and use, regarding improving rural access to primary care.

Study Design: By analyzing the stock of over 5,000 publications on this topic, generated from a literature review, we employ Citation Network Analysis to elicit the knowledge production system and Social Network Analysis to gauge the most powerful players in the network via centrality measures. Using a generalizable normative model of knowledge production, based on Gibbons et al. (1994), we evaluate how the system performs in terms of two scaled indicators: multidisciplinarity and heterogeneity.

Population Studied: The knowledge production system entails all authors and organizations that have written or were cited within publications from the literature review. The review includes all publications from 1993 to the present that address rural populations in the United States, access, and primary care, defined as clinical care for all physical, mental, and behavioral conditions, ranging from screening through monitoring.

Principal Findings: Our findings suggest that the knowledge production system is highly concentrated within academic institutions, certain government agencies, the South Atlantic geographic region of the United States, and within family medicine departments. The networks for both authors and sources grew by 67 percent over the study period and decreased in density and overall centralization. Analysis of
top authors and sources showed increased centrality of new disciplines (e.g. dentistry and mental health), chronic diseases (e.g., cancer and diabetes), government agencies, and health policy.

**Conclusions:** The knowledge production system became more multidisciplinary over the study period but heterogeneity remained consistent in terms of types of knowledge producers and geography. This suggests that the system is open to innovation from new disciplines that can offer new perspectives and approaches to the workforce and access issue. As the system becomes more decentralized and multidisciplinary, however, innovation is restricted by concentrated sites and knowledge producers.

**Implications for Policy, Delivery, or Practice:**
This study stresses the importance of continuing and enhancing multidisciplinary approaches to studying and developing solutions for primary care access issues, including disadvantaged rural populations. It also implies that research funders and researchers (academic, practitioner, government, foundation, think-tank, etc.) should diversify their efforts and funding across more heterogeneous sites to be more reflexive to stakeholders.

**Hospital Adherence to Policies: Evaluation of Operating Room Nurse Staffing Policy Review**
Melissa Bathish, PhD(c), RN, CPNP-PC; University of Michigan School of Nursing; Akkeneel Talsma, University of Michigan; Margaret McLaughlin, PhD, RN, University of Michigan School of Medicine

**Presenter:** Akkeneel Talsma, Ph.D., R.N., Assistant Professor, Surgery - Transplant, University of Michigan, antalsma@umich.edu

**Research Objective:** Numerous studies have evaluated the role of unit based nurse staffing levels and patient outcomes and linked with quality of care outcomes. Little is known about the characteristics of operating room (OR) nurse staffing, as it does not follow the unit staffing format. OR nurses are assigned to one OR room for each procedure, unlike unit nurses who care for multiple patients at the same time. Staffing policies and guidelines provide a framework for evaluating the relationship between nurse staffing and quality patient care.

Therefore, the purpose of this study was: (1) To review nurse staffing policies in ORs of hospitals within the Perioperative Outcomes Initiative (POI), a Michigan quality collaborative, and (2) To compare policies to staffing guidelines of the Association of periOperative Registered Nurses (AORN). The Quality Health Outcomes Model (QHOM) guided this study. The QHOM is an extension of the structure-process-outcome-model, using bidirectional relationships among its main constructs (system, interventions, client, and outcomes). Thus, surgical patient outcomes affect and are affected by staffing (system characteristic).

**Study Design:** All 17 hospitals participating in POI were invited to submit OR staffing policies for review. Agreements were established to only share aggregate and de-identified information, such that the hospital name was not disclosed to members of the collaborative.

**Population Studied:** A descriptive, exploratory study was conducted. The submitted OR staffing policies were reviewed and compared with parameters from AORN’s perioperative staffing recommendations and guidelines. Descriptive analyses identified frequencies and percentages of parameters included in hospital staffing policies consistent with the AORN framework.

**Principal Findings:** Response rate to policy submission within the consortium was 35% (6/17). The hospitals that did not submit a policy for review cited the following reason(s): (a) policy did not exist, (b) no permission received from leadership to submit for review, (c) labor related contracts prohibit release of the policies for review. A majority, 67% (4/6) of the reviewed policies included the policy purpose and provided direction about direct patient caregivers. Half of the policies included an AORN-derived guidance statement individualized to the organization and identified a minimum requirement of one registered nurse per OR suite for a surgical procedure. Productive and non-productive time and provisions for emergent procedures were included in 33% (2/6) of policies. Very few (16%; 1/6) policies identified provisions for unplanned procedures, number of scrub persons per procedure, call staffing, or flexible staffing formulas.

**Conclusions:** This study indicates that perioperative nurse staffing policies lack many of the components included recommended AORN guidelines. In particular, guidelines pertaining to flexible staffing guidelines, provisions for
The Great Recession of 2007 and California Nurses: A Descriptive Analysis
Michelle Tellez, California State University, East Bay; Pamela Neronde RN BSN, ; Sherly Wong, Student RN, California State University East Bay

Presenter: Michelle Tellez, Ph.D., R.N., Assistant Professor, Nursing and Health Science, California State University, East Bay, michelle.tellez@csueastbay.edu

Research Objective: To investigate the effect of the Recession of 2007 on nurses’ wages, demographics, human capital, and work environment characteristics.

Study Design: Descriptive study using data collected by the California Board of Registered Nursing Surveys of 2006, 2008 and 2010.

Population Studied: Nurses working and residing in the state of California who earned a wage and were less than 75 years old. Once selection criteria were enforced 7767 nurses were included in the study.

Principal Findings: The Recession eliminated secondary nursing positions. Although 30% of nurses worked part-time in 2010, nurses worked on average 51 weeks a year in their primary nursing positions. Household incomes were stable though continuous increase in wages. Location of employment and job title changed over this period with more nurses working in ambulatory care settings and more individuals holding advanced practice titles. Nurses are more satisfied with their work environment and most do not intend to leave, although 30 would like to work fewer hours a week. Less than 50% of California nurses held a BSN degree or higher at the time of the surveys. Their average age was 48, and the majority was either White or Asian.

Conclusions: As the economy recovers, secondary nursing positions will re-appear and the nurse shortage will re-surge.

Implications for Policy, Delivery, or Practice:
Intense focus in three policy areas is recommended: education, faculty training, and recruitment and retention of African Americans, Hispanics, and older nurses. Nursing educational enrollment must be maintained at the present levels, and additional emphasis must be placed in the recruitment of students of color. Strides made in the number of students admitted to nursing programs the past 10 years cannot be lost. Faculty shortage is a well-known problem that continues to plague the nursing educational system. Nurse faculty training programs and loan re-payment incentives programs are essential to bringing more individuals in the field of education. A focus on conflict management and leadership training can assist the recruitment and retention of Hispanics and African American nurses. Flexible work environments and teaching programs may be able accommodate older nurses. Keeping older, more experienced nurses in the labor supply as resources and mentors may facilitate the entry of new graduates while ensuring a high skill in the workplace.

Public Opinions Regarding Advanced Dental Hygiene Practitioners in a High-Need State
Sarah Walsh, Foundation for a Healthy Kentucky; Jennifer Chubinski, Health Foundation of Greater Cincinnati; Eric Rademacher, The Institute for Policy Research at the University of Cincinnati

Presenter: Sarah Walsh, M.P.H., Knowledge Officer, Foundation for a Healthy Kentucky, swalsh@healthy-ky.org

Research Objective: The American Dental Hygienists’ Association has developed a set of professional competencies for a new type of oral health professional: the Advanced Dental Hygiene Practitioner (ADHP). It is hoped that the ADHP will increase access to oral health care for the general population, particularly in rural and underserved areas. In order for this strategy to be successful, the public must feel comfortable with the care provided by ADHPs and seek out their services. This study
assessed consumer receptivity to the ADHP in a particularly high need area: Kentucky. As a point of comparison, respondents were also asked about their comfort with care provided by two other so-called “mid-level” clinicians already licensed in the state, advanced practice register nurses (APRN) and physician assistants (PA).

**Study Design:** A random sample of 1,680 adults from throughout Kentucky was interviewed by telephone as part of the annual Kentucky Health Issues Poll. Specifically, 1,360 landline interviews and 320 cell phone interviews were conducted between September 20 and October 14, 2012. Sample responses were weighted based on American Community Survey estimates for gender, race, age, educational attainment and region of Kentucky.

**Population Studied:** This study polled a representative sample of adults from a state with significant oral health challenges and limited access to care. According to the 2010 Behavioral Risk Factor Surveillance System (BRFSS), 27.4% of Kentucky adults over age 65 have had all of their natural teeth extracted, trailing only Tennessee and West Virginia for the highest rate of edentulous seniors in the nation. Just 63.2% of Kentucky adults reported seeing a dentist for any reason in the past year, according to the 2010 BRFSS. Only 5 states report lower rates of dental access. Kentucky typifies the types of oral health needs that the ADHP profession was created to address.

**Principal Findings:** After hearing a brief description of the profession, nearly 3 in 4 Kentucky adults said they would be somewhat (35.4%) or very (38.2%) comfortable seeing an ADHP for routine dental care. Just 1 in 6 said they would be somewhat (7.7%) or very (8.5%) uncomfortable seeing an ADHP. An additional 6.6% said they would be neither comfortable nor uncomfortable seeing an ADHP and 3.6% did not have an opinion. The total proportion of Kentucky adults who were comfortable seeking care from an ADHP (73.6%) was less than the proportion indicating comfort seeing an APRN (79.7%) or PA (81.3%). In general, respondents who were younger, who had higher incomes, and who were in better overall health were more likely to be comfortable with an ADHP.

**Conclusions:** For all demographic sub-groups studied, the majority of Kentucky adults would be somewhat or very comfortable seeing an ADHP for routine dental care. While Kentuckians reported less comfort with ADHPs than with other “midlevel” clinicians, this may be related to a lack of direct experience with ADHPs.

**Implications for Policy, Delivery, or Practice:** Adults are receptive to new models of care delivery and report high levels of comfort with ADHPs. Consumer concerns are unlikely to be a barrier to expanded licensure for dental hygienists in high need areas like Kentucky.

**The Association Between Medical Student Career Interests and Attitudes Toward Primary Care, Faculty Mentorship, and Institutional Support**

Charlotte Ward, Massachusetts General Hospital; Susan Edgman-Levitan, Massachusetts General Hospital; Marya J. Cohen, Massachusetts General Hospital; Rebecca A. Berman, Massachusetts General Hospital

**Presenter:** Charlotte Ward, M.P.H., Research Analyst, Massachusetts General Hospital, cward0@partners.org

**Research Objective:** The Crimson Care Collaborative (CCC), a series of 5 student-faculty collaborative practices, aims to give medical students hands-on practical experience in primary care practices across the Harvard Medical School network, with the hope that these students will be more inclined to pursue a career in primary care after they graduate. We surveyed medical students prior to participating in CCC. Our goal was to examine the relationship between student career interest and faculty mentorship, institutional support and attitudes toward primary care.

**Study Design:** All Harvard Medical School (HMS) students who joined the Crimson Care Collaborative as student-volunteers were administered a survey prior to volunteering which asked questions about their career interests, attitudes toward and knowledge about primary care, and presence of faculty mentoring. Survey responses were compared with Chi-square tests.

**Population Studied:** The study population included 129 HMS students who filled out a survey prior to participating in CCC.

**Principal Findings:** Among students who reported having a faculty mentor at HMS within the field of general medicine, reported interest was higher in general medicine than specialty medicine (60%, vs. 8%, p <0.0001). Students...
interested in general medicine were more likely to report having met a HMS faculty member whose general medicine career is one they would like to emulate (59% vs. 15%, p < 0.001) and to report having disagreed with negative comments that they heard about primary care from either faculty, residents, or their peers (86% vs. 45%, p < 0.001) compared to students interested in specialty medicine. Students interested in general medicine were less likely to report that there was institutional support for future primary care careers than students not interested in general medicine (38% vs. 69%, p = 0.002). There were no significant differences in student-reported importance of income, ability to pay back loans, or amount of student debt between students interested in general medicine versus specialty medicine.

Conclusions: Harvard Medical School students interested in general medicine were more likely to report having faculty mentors and members that they emulate in the fields of general medicine, more likely to disagree with negative comments that they had heard in regard to primary care, but were less likely to report the presence of institutional support. The ability to pay back loans, student debt and importance of income were not associated with career interest, in contrast to previous studies. Our study finds that there are other factors, aside from student debt and income, that play a role in primary care career interest.

Implications for Policy, Delivery, or Practice: By expanding Medicaid and providing federal subsidies to help lower-income individuals purchase private insurance, the Affordable Care Act will extend insurance coverage to 30 million new patients, many of whom will likely need a PCP. It will be important to attract a greater number of medical students to the field of primary care. Our study provides insight into the factors that contribute to student career interests and focusing on these factors as a means of attracting more students to primary care could be valuable for medical institutions to pursue.

Patient Safety Knowledge and Attitudes of Medical Students at Various Stages of Training: A Cross-Sectional Analysis

Donna Woods, Northwestern University; Paul S. Jansson, BA, Northwestern University; David H. Salzman, MD, MEd, Northwestern University; Yuemi An-Grogan, MD, Northwestern University; Lindsay A. DiMarco, MPH, Northwestern University

Presenter: Donna Woods, Ph.D., Ed.M., M.A., Assistant Professor, Feinberg School of Medicine, Northwestern University, woods@northwestern.edu

Research Objective: Medical error is a leading cause of morbidity and mortality in the United States. Formal training in patient safety is a vital, yet neglected, component of undergraduate medical education. This study reports the initial results of a cross-sectional analysis of medical student patient safety knowledge and attitudes at a single medical school at various stages of training.

Study Design: All participants were asked to complete two validated assessments:

1) Attitudes to Patient Safety Questionnaire, 3rd edition (APSQ-III), which measures nine subscores and a global score of patient safety on a 1-7 Likert scale, and 2) Risk Management Foundation (RMF) Patient Safety Knowledge Test, a 14-item multiple-choice assessment. First year students (M1) were recruited on their second day of medical school, second year students (M2) in the second month of classes, and fourth year students (M4) during the Emergency Medicine Clerkship. The patient safety assessment data was then analyzed to evaluate student patient safety knowledge and attitudes overall, by class and to compare patient safety knowledge and attitudes across the stages of medical education.

Population Studied: Medical students, in the first, second, and fourth year of medical school training during the 2012-13 academic year (N=314).

Principal Findings: 155 M1, 75 M2, and 84 M4 students completed both assessments (N = 314).

M4 students scored modestly higher than M1 and M2 students on the knowledge assessment, 59.5% vs. 51.0% and 51.6%, respectively (p < 0.05).

There were no statistical differences in the global scores between the M1, M2, and M4 students on the APSQ-III (5.46, 5.33, 5.44, respectively). There were no significant differences between classes in the Error Reporting Confidence (4.94, 5.02, 4.94), Error Inevitability (6.33, 6.24, 6.34), Disclosure Responsibility (5.48, 5.22, 5.21), or Patient Involvement in Reducing Error (5.43, 5.39, 5.62) sub-scores. While M4 students had less
favorable attitudes than M1 or M2 students in Working Hours as Error Cause (4.90 vs. 5.67 and 5.39), the M4 students had more favorable attitudes on Patient Safety Training Received (5.41 vs. 4.28 and 4.44), and Professional Incompetence as Error Cause (5.38 vs. 4.99 and 5.05). M1s had more favorable attitudes than M2 and M4 students in Importance of Patient Safety in Curriculum (6.05 vs. 5.48 and 5.40).

Conclusions: While there was a modest positive shift in knowledge and some attitude sub-scores in the domains of patient safety across the four years of medical training, the M4 scores do not demonstrate competence.

Implications for Policy, Delivery, or Practice: Current medical educational frameworks are training medical students to achieve patient safety competence. The incremental increase in knowledge from M1 to M4 year (51-59%) means medical students are graduating medical school unprepared for the current expectations of quality and safety competence in residency and medical practice. To address the significant quality and safety challenges in our healthcare system, it is critical for medical students to achieve quality and safety competence. It is therefore essential to meaningfully integrate quality and safety knowledge, attitudes, and skills, acquisition into medical student learning and into the medical education curricular requirements.

The Effect of Prior Health-Related Employment on the Wages of Registered Nurses
Byung-kwang Yoo, UC Davis, School of Medicine; Minchui Kim, Department of Public Health Sciences, School of Medicine, University of California, Davis, CA, USA; Tomoko Sasaki, Independent consultant; Joanne Spetz, Philip R. Lee Institute for Health Policy Studies & School of Nursing, Center for the Health Professions University of California, San Francisco, CA, USA

Presenter: Byung-kwang Yoo, M.D., Ph.D., M.S., Associate Professor, Department of Public Health Sciences, UC Davis, School of Medicine, yoobk3@gmail.com

Research Objective: Among all registered nurses (RNs), the proportion of RNs with prior employment in health-related positions before completing their initial RN education was 67% in 2008, having increased steadily from 29% in 1992. Prior research found that prior health-related employment is positively associated with the workforce supply. Our objective is to examine whether prior health-related employment was associated with differences in wages, particularly the wage increases received for greater years of experience as an RN.

Study Design: We conducted a cross-sectional analysis, implementing a multivariate ordinary least squared model where the outcome variable was the logarithm of the RN hourly wage. The key covariates included interaction terms between years of experience, experience squared, and six categories of prior health-related employment: Licensed Practical Nursing (LPN), Nursing Aide, Allied Health, Clerk, Manager and all other health-related positions. Additional covariates are whether the RN works more than 40 hours per week, gender, marital status, race, highest nursing degree, and region. We estimated the marginal effect of experience for each of prior health-related employment categories.

Population Studied: The National Sample Survey of Registered Nurses (NSSRN) 2008 (N=20,385), excluding subjects who did not work as RN or worked only part-time.

Principal Findings: Among six categories of prior health-related employment, only RNs with prior employment as LPN were found to statistically differ in the wage received over time, compared to those without prior health-related employment (control group)(p<.05). The LPN group had both a relative advantage and a relative disadvantage compared to the control group. The advantage was observed as a higher starting annual salary for full-time workers ($52,000), which is $2,000 higher. The relative disadvantage is that the returns to experience are lower for those with prior LPN employment. For instance, when experience increased from 5 years to 6 years, the hourly wage increased by $0.27 for the LPN group and $0.38 for the control group. RNs with prior LPN experience earn a higher wage until they have accrued approximately 10 years of experience.

Conclusions: The LPN group had a higher start wage but a lower experience-based wage increase compared to RNs who did not have prior health-related experience. This lower return to experience offsets the initially higher wage once experience exceeded 10 years.

Implications for Policy, Delivery, or Practice: RNs who previously worked as LPNs are an important component of the RN workforce; prior research has found them to have greater
workforce supply than RNs who do not have health-related experience. However, the differences in the wages of RNs with prior LPN experience versus those without may reflect different skills at the start of an RN’s career versus later in the career. The higher initial wage for RNs with prior LPN experience suggests that employers find that RNs with prior experience are more productive when they have little RN experience. However, the higher return to experience for RNs who were not previously LPNs suggests that there are differences in human capital accumulation between these groups. Future research should examine the underlying causes of this difference and whether educational or training interventions could increase the productivity of LPNs with experience.

**The Impact of Economic Recession on the Registered Nurse Workforce Supply**

Byung-kwang Yoo, UC Davis, School of Medicine; Minchui Kim, Department of Public Health Sciences, UC Davis School of Medicine, Davis, CA, USA; Tomoko Sasaki, Independent consultant

**Presenter:** Byung-kwang Yoo, M.D., Ph.D., M.S., Associate Professor, Department of Public Health Sciences, UC Davis School of Medicine, yoobk3@gmail.com

**Research Objective:** The severe economic recession starting in 2008 has substantially influenced the registered nurse (RN) workforce supply at the national level. Our objectives are (1) to examine the specific effect of the supply determinants in 2008 and 2010, separately, and (2) to compare the change in these effects between years 2008 and 2010.

**Study Design:** We first conducted the cross-sectional analysis by running multivariate regression models where the dichotomous dependent variable indicated whether working as RNs or not. The covariates included age (5 groups), market RN wage (predicted for all subjects), other income, gender, race, marital status, highest RN-related education attained, residential regions and others. We then compared the estimated coefficients of each covariate between 2008 and 2010. Our hypotheses are that older RNs became more likely to work in 2010 and that RNs became less sensitive to market RN wage and other income in choosing to work as RNs in 2010, compared to 2008.

**Population Studied:** 2008 and 2010 California Board of Registered Nursing data (un-weighted/weighted N=4,239~4,495/241,000~245,000 per year) was used as the largest dataset available for our objectives, because the National Sample Survey of Registered Nurses did not collect data after 2008.

**Principal Findings:** Among all RNs, the proportion working as RNs declined very slightly from 88.0% (2008) to 87.6% in 2010. However, the effects of some determinants significantly changed during this period, supporting our hypotheses. For instance, RNs aged 40-59 were 75~84% (odds ratio (OR)=0.16~0.25, p<.05) less likely to work as RNs compared to the youngest reference group (aged younger than 30) in 2008. This difference disappeared in 2010. Although the oldest age group (aged over 60) was still less likely to work than the reference youngest group in 2010, its OR increased from 0.04 (2008) to 0.19 (2010). Namely, all older RN groups (aged over 40) became more likely to work in 2010, compared to 2008. Also, RNs became less sensitive to financial factors in 2010, compared to 2008. Specifically, when a predicated hourly market wage increased by $1 from its mean value ($45), RNs were 8% more likely to work as RNs in 2008 (p<.05). This statistically significant association between the market wage and the working status became insignificant in 2010 (p>.3).

**Conclusions:** Our analyses quantified the substantial economic recession impacts on the RN workforce supply in California State. Despite the constant proportion of working RNs during this period, the average age of working RNs increased significantly which is consistent with the reported difficult job search among younger RNs. The less sensitiveness to wage and other income in 2010 suggests the serious financial need of RNs’ households.

**Implications for Policy, Delivery, or Practice:** Policy implications include expanding job opportunities for younger RNs and offering flexible schedules for working older RNs. The constant proportion of working RNs implies that
the healthcare industry is securing household income during a severe economic recession accompanying a high unemployment rate at the national level.

**HEALTH INFORMATION TECHNOLOGY**

**Health Information Exchange Two Years into HITECH**
Julia Adler-Milstein, University of Michigan; David W. Bates, Partners Healthcare; Ashish K. Jha, Harvard School of Public Health

**Presenter:** Julia Adler-Milstein, Ph.D., Assistant Professor, School of Information, University of Michigan, juliaam@umich.edu

**Research Objective:** A core aim of the 2009 HITECH Act is to foster the development of broad-based electronic health information exchange (HIE). Federal efforts have focused on promoting HIE by both including it as a part of Meaningful Use and through direct funds to states to build out HIE infrastructure. Whether the current efforts have led to further expansion of health information exchange is not yet known. We therefore performed a national survey of all HIE efforts to determine the growth in the number of efforts, what kinds of data they are sharing, how many providers they have engaged, whether they are financially viable, and their most substantial challenges to development.

**Study Design:** In the fall of 2012, we surveyed all organizations in the U.S. that facilitate exchange of clinical data between independent entities. We began with our list of efforts from three prior national HIE surveys and supplemented this list with those in the eHealth Initiative directory of HIE efforts and those listed on state and federal government websites. We implemented a web-based survey that asked respondents to report whether they were actively exchanging clinical data, key organizational demographics, types of data exchanged, funding sources, and barriers to development.

**Population Studied:** A national census of local, regional, and state-based organizations engaged in facilitating clinical data exchange between independent entities.

**Principal Findings:** Our response rate was 78% (172/221). We found that since our last national survey in early 2010, there had been substantial growth in the number of entities that are actively sharing clinical data (a 61% increase from 75 in 2010 to 119 in 2012). We found that 1,398 U.S. hospitals (27% of U.S. community hospitals) and 23,341 ambulatory practices (10% of U.S. practices) participated in the 119 operational HIE efforts, more than double the proportion of providers who
participated in 2010. Test results, followed by patient summary care records, were the most common types of data exchanged. More than half of all operational HIE efforts (52%) reported that grants were the most substantial source of support while less than a quarter (24%) reported being able to cover operating costs with revenue from participants. Nearly three out of four operational efforts identified developing a sustainable business model as a major barrier to development.

Conclusions: While HITECH support for HIE has spurred a large increase in the number of organizations facilitating clinical data exchange and the number of participating providers, substantial barriers related to financial viability remain.

Implications for Policy, Delivery, or Practice: Our findings offer the most up-to-date assessment of the state of health information exchange in the U.S. For policymakers, the considerable growth in the number of HIE efforts is early evidence of the beneficial impact of HITECH. However, there are substantial challenges facing HIE efforts, with long-term financial sustainability being at the top of the list. Given that federal funds to support these efforts are soon to run out, we need new attention on identifying sustainable business models. Failure to do so will lead to islands of clinical data with little connectivity, which will impede broader efforts to improve the healthcare delivery system.

Hospital Uptake of the Meaningful Use Incentive Program
Julia Adler-Milstein, University of Michigan; Michael Furukawa, Office of the National Coordinator for HIT; Jennifer King, Office of the National Coordinator for HIT; Ashish K. Jha, Harvard School of Public Health

Presenter: Julia Adler-Milstein, Ph.D., Assistant Professor, School of Information, University of Michigan, juliaam@umich.edu

Research Objective: The centerpiece of the 2009 HITECH Act is incentives for providers to adopt and become "meaningful users" of electronic health records (EHRs) in order to address persistent quality and efficiency challenges stemming from reliance on paper-based records. We sought to assess whether the incentives are sufficient to prompt hospitals to become meaningful users, whether uptake is evenly spread across different types of hospitals, and what types of hospitals are advanced in their ability to meet meaningful use criteria.

Study Design: We used data from CMS, the agency administering the incentive program, to determine which hospitals attested to being a meaningful user of EHRs under the Medicare and/or Medicaid program as of 10/31/2012. We categorized hospitals not attesting to meaningful use into the following three groups: those that met the adopt-implement-upgrade (AIU) option under the Medicaid program, those that only registered for the meaningful use program, and those that did not register or participate.

Using data on hospital characteristics from the American Hospital Association survey, we first assessed the percent of hospitals and discharges that attested to meaningful use, as well as the other three hospital participation categories. We then built multivariate models to assess which characteristics differentiate hospitals that attested to meaningful use versus those that did not. We also examined hospitals that have been paid (attesting to meaningful use + AIU option) versus those that had not. Finally, among hospitals that had attested to meaningful use, we assessed which were particularly advanced, defined as those that could meet all criteria at least 90% of the time.

Population Studied: All Medicare certified hospitals eligible for the meaningful use program that responded to the AHA annual survey (n=4,837)

Principal Findings: 2,286 hospitals (47% of hospitals representing 55% of discharges) attested to meaningful use as of 10/31/12. Another 1,145 hospitals (24% of hospitals, 25% of discharges) received payments under the AIU option. 639 hospitals (13% of hospitals, 12% of discharges) registered for the program but did not receive payment, leaving 767 hospitals (16% and 9% of discharges) not engaged.

Larger hospitals, urban hospitals, and non critical access hospitals (CAHs) were more likely to have attested to meaningful use compared to all other hospitals (Odds Ratio=1.3 for medium, p=0.001; OR=1.7 for large, p<0.001; OR=1.2 for rural, p=0.01; OR=0.8 for CAH, p=0.03). Larger hospitals and non CAHs were also more likely to get paid. We found a broader set of characteristics that differentiated highly sophisticated meaningful users; they were more likely to be small, urban, not-for-profit, system affiliated, offer an HMO product, and be a CAH.
Conclusions: Initial program results suggest high rates of uptake with more than 1 in 3 hospitals attesting to meaningful use and more than half receiving some form of payment. Hospitals that attested to meaningful use were generally larger and not critical access. Among those who attested, however, CAHs were more likely to be sophisticated users.

Implications for Policy, Delivery, or Practice: The early findings from the Meaningful Use incentive program suggest that we need to focus on small, rural, and critical access hospitals that appear to be falling behind in their ability to meet meaningful use.

The Role of HIT in the Patient-Centered Medical Home
Julia Adler-Milstein, University of Michigan;
Genna Cohen, University of Michigan

Presenter: Julia Adler-Milstein, Ph.D., Assistant Professor, School of Information, University of Michigan, juliaam@umich.edu

Research Objective: The HITECH Act seeks to promote widespread adoption of health information technology (HIT) in order to address persistent quality and efficiency challenges facing our healthcare delivery system, many of which derive from reliance on paper records. HITECH also lays the infrastructure for broader efforts to reform healthcare delivery by supporting new models for care delivery. While the role of HIT is thought to be critical, we know little about the extent to which those pursuing new care delivery models are relying on HIT and which specific types of HIT are most widely adopted. We therefore studied a large patient-centered medical home demonstration project in Michigan to assess which types of HIT were most widely used, and how adoption rates changed over time as PCMH practices matured.

Study Design: We leverage survey data collected from practices participating in a Blue Cross Blue Shield of Michigan PCMH demonstration project, which began in 2005. Survey data was collected semi-annually from a practice representative between 2010 and 2012 (a total of four periods). We use descriptive statistics to characterize the most highly adopted HIT functionalities in the initial survey among the four included (patient registry, patient portal, electronic health record, ePrescribing), as well as the functionalities for which adoption increased the most over the two year period between the first and last survey.

Population Studied: 2,171 practices participating in the physician group incentive program, a PCMH demonstration project sponsored by Blue Cross Blue Shield of Michigan for practices throughout the state. We limited our analyses to practices reporting data in all four periods, approximately half of all participants in the program.

Principal Findings: The most highly adopted HIT functionality within PCMH practices was ePrescribing (69%) followed by patient registries (51%). EHRs and patient portals were less often adopted (in 36% and 19% of practices respectively). Over a two-year period, ePrescribing and EHRs were the functionalities most often newly adopted – a twelve percentage point increase for both. Adoption rates were half for patient registries (a 6 percentage point increase) and patient portals (a 5 percentage point increase).

Conclusions: Among PCMH practices, we found widespread use of HIT and increasing adoption over time. There were large differences, however, in the types of HIT functionality implemented in practices as well as differences in adoption over time. Adoption of the two clinically-oriented functionalities, ePrescribing and EHRs, increased the most. While patient registries, the primary population-management functionality, were implemented in more than half of practices at the outset, adoption did not increase substantially over time. Patient portals, which would be expected to be in widespread use given the patient-focused nature of PCMHs, were neither widely implemented at the outset nor widely adopted over time.

Implications for Policy, Delivery, or Practice: This study is among the first to report the types of HIT in use in PCMH practices, suggesting which functionalities may be most essential to achieving the aims of better coordinated and more patient-centered care. Given the observed emphasis on provider-focused functionalities, it will be critical to understand why IT is not being leveraged as heavily to manage population health and engage patients.

Health Information Technology and Hospital Performance on Imaging-use Measures
Ajit Appari, Dartmouth College; M. Eric Johnson, Dartmouth College; Denise Anthony, Dartmouth College

Presenter: Ajit Appari, Ph.D., Research Fellow, Center for Digital Strategies at Tuck, Dartmouth College, ajit.appari@tuck.dartmouth.edu

Research Objective: A growing body of evidence suggests that US hospitals over utilize imaging services. While imaging serves a critical role in diagnostics and improving care delivery, it may cause unintended clinical consequences if overused and certainly increases cost. Recently, Jason Mathias and colleagues reported wide variations in imaging utilization across US hospitals, and abnormally high use at rural, for-profit hospitals. The widespread diffusion of health information technology (IT) is expected to improve accessibility of clinical and imaging reports leading to delivery of efficient imaging care, and reducing repeat imaging. This study examines the associative relationship between hospitals’ health IT capability and performance on select imaging use measures.

Study Design: We analyzed data from three sources: operational status of clinical applications from HIMSS-2009 release of health IT inventory; performance on outpatient imaging-use measures (percentage MRI studies of lumbar without antecedent conservative therapy, follow-up imaging after screening mammography, and proportion of CT studies of chest and abdomen with and without contrast) during 2011 from Hospital Compare; and market level (hospital referral region) aggregate imaging event rate per 1000 beneficiaries from Health Indicator Warehouse. Hospitals were rated as Intermediate health IT capability if it has one or more of integrated PACS system, image distribution capability over web, and clinical decision support with physician pathways in addition to clinical applications required to meet the Stage-1 requirements of EHR incentive program. Hospitals with lesser than Stage-1 capability were used as reference group, and rated as Advanced health IT capability if all three system capabilities and Stage-1 capable EHR system. Since all dependent variables are facility level risk standardized rates, the analysis was performed by fitting a GLM with gamma-log link function, in STATA 12, adjusting for structural characteristics including academic status, critical access hospital, membership to multihospital system, rural location, participation I cardiac registry, staffed bed size, outpatient visits volume, market level imaging event rate. The endogeneity issue of health IT adoption was addressed by including propensity for having Stage-1 capable health IT systems. For each dependent variable separate regression models were estimated by stratifying hospitals on profit status.

Population Studied: 3316 non-federal acute care hospitals

Principal Findings: Among non-profit hospitals, users of advanced health IT system have lower imaging utilization rates for CT scan of abdomen (incidence rate ratio IRR: 0.81, 95% CI [0.67, 0.96]), and chest (IRR: 0.67, CI [0.48, 0.93]), and MRI of lumbar (IRR: 0.74, CI [0.63, 0.86]). Additionally, intermediate health IT hospitals had lower rates for follow-up imaging after screening mammogram (IRR: 0.87, CI [0.76, 0.99]). However, among for-profit hospitals, only advanced health IT users had lower utilization rates for CT scan of abdomen (IRR: 0.62, CI [0.45, 0.87]) and MRI of lumbar (IRR: 0.67, CI [0.48, 0.93]).

Conclusions: Our findings suggest that non-profit hospitals with advanced health IT systems perform better on most imaging-use measures. We find limited support for hospitals with intermediate health IT capability.

Implications for Policy, Delivery, or Practice: Recent report raises concern over excessive utilization of imaging services, even though the growth rate has stabilized. Within the broader framework of the ongoing electronic health record incentive program, this study could inform policy makers as well hospital administrators on potential benefits of advanced health IT.

The Role of the PCP in Preventive Cancer Screening Using a Novel Population Management System: Results of a Practice-Randomized Trial
Steven Atlas, Massachusetts General Hospital; Jeffrey M. Ashburner, Massachusetts General Hospital; Adrian H. Zai, Massachusetts General Hospital; Yuchiao Chang, Massachusetts General Hospital; Sanja Percac-Lima, Massachusetts General Hospital; Richard W. Grant, Massachusetts General Hospital

Presenter: Steven Atlas, M.D., Director, Primary Care Practice-based Research And Quality
Research Objective: Preventive cancer testing rates remain suboptimal despite known benefits of screening and use of visit-based reminders. Advances in health information technology (HIT) now permit population-based screening, but the best methods remain uncertain. We implemented a novel visit-independent, population management system within a large primary care (PC) network and compared two versions: one that involved PC providers (PCPs) in patient screening and one that did not. We hypothesized that involving PCPs would lead to more effective and efficient cancer screening. Study Design: We randomized 18 PC sites within an academic network to intervention (n=9) or augmented usual care control (n=9) groups. All practices employed a novel HIT system that identified patients overdue for screening, mailed reminder letters, and tracked scheduling and completion of screening; used scheduling delegates to assist patients; and had access to patient navigators for those at high risk for non-adherence. In intervention practices, physicians (for their patients) and population managers (for other practice patients) personally screened real-time rosters of patients overdue for screening, and could choose an individualized method of patient contact (reminder letter, referral to scheduling delegate, referral to patient navigator) or defer screening. In control practices, all overdue patients were initially sent a reminder letter without provider review and then transferred to a delegate list. Intervention patients without provider action within 8 weeks defaulted to the automated control version. We examined average cancer screening test completion over 1-year of follow-up for each eligible patient and all eligible cancers using a mixed effects model accounting for clustering by PCP or practice and adjusting for patient age, race, insurance, language, and time since last visit. Population Studied: Patients eligible for preventive breast, cervical and colorectal cancer screening. Principal Findings: Among 104,074 eligible patients, baseline screening rates were similar in intervention and control patients for breast (79.4% vs. 79.8%), cervical (80.9% vs. 82.0%), and colorectal (77.6% vs. 76.4%) cancer. Small but statistically significant differences in patient characteristics for age, gender, ethnicity, language spoken, insurance status and time since last visit were seen among intervention (n=51,166) and control (n=52,908) patients (all p<0.001). Most intervention providers used the tool (88 of 98, 90%) and reviewed 8115 patients overdue for at least 1 cancer screening (6017 selected to receive a reminder letter, 407 referred directly to a scheduling delegate, 48 referred to a patient navigator, and 1744 were deferred from screening). An additional 6159 letters were sent to intervention patients not reviewed by a provider (total 12,176 letters). In control practices, 17,237 patient letters were mailed. Adjusted average cancer screening rates did not differ among intervention and control practices for all cancers combined (79.6% vs. 79.6%, p=0.87), or breast (79.7% vs. 79.7%, p=0.98), cervical (80.6% vs. 81.3%, p=0.58), or colorectal cancer (78.0% vs. 77.5%, p=0.78). Conclusions: Involving providers in a visit-independent, population management HIT system for breast, cervical or colorectal cancer screening did not increase screening rates compared to an automated reminder system. Implications for Policy, Delivery, or Practice: Similar screening rates were achieved with fewer patient contacts in intervention practices. Funding Source(s): AHRQ Poster Session and Number: A, #350

Accelerating Primary Care Physicians’ Advanced HIT Practice Transformation Through Technical Assistance Programs and Payment Reform Michelle Doty, The Commonwealth Fund; Anne-Marie Audet, The Commonwealth Fund; David Squires, The Commonwealth Fund

Presenter: Anne-Marie Audet, M.D., Vice President, Quality Improvement and Efficiency, The Commonwealth Fund, ama@cmwf.org

Research Objective: The HITECH Act of 2009 created an extension program offering technical assistance to physicians and financial incentives to support health information technology (HIT) adoption and meaningful use. Evidence suggests that physicians are adopting HIT tools, yet less is known about use of HIT to achieve advanced functionalities. This study describes the variation in primary care physicians’ (PCP) use of various HIT functions; and explores whether sharing resources for technical assistance, being part of an integrated delivery system, and receiving financial incentives for
enhanced primary care activities affect advanced HIT capacity.

**Study Design:** Data come from the 2012 and 2009 Commonwealth Fund International Health Policy Surveys of Primary Care Physicians, collected by mail among a nationally representative sample of U.S. PCPs. Based on survey questions, we created six categories to describe physicians’ use of HIT: 1) generate patient information, 2) generate patient registry and panel information, 3) order entry management, 4) decision support, 5) patient access, and 6) health information exchange. Data were collected on practice size, setting (e.g., part of an integrated delivery system), physicians sharing resources for technical support for information systems or quality improvement consultants, and financial incentives for enhanced primary care activities (e.g., preventive care, managing chronic conditions, medical home fees). We employed multivariable logistic regression to analyze whether participating in integrated delivery system, sharing technical assistance, and financial incentives were associated with greater HIT capacity.

**Population Studied:** PCPs

**Principal Findings:** PCPs’ HIT capacity increased between 2009 and 2012 with variation among functionalities. The largest increases are in electronically prescribing medications (40% to 64%*), electronic transmission to pharmacy (34% to 66%*), and electronic drug alerts (37% to 58%*). Electronic access to clinical data to manage individual patients (30% to 45%*) or panels (29% to 42%*) has also increased. Only 33% of physicians say they can exchange clinical summaries with doctors outside their practice, and 28% say their patients can access their information on a secure website. Physicians that participate in an integrated delivery system are more likely (OR=1.55*) to achieve “multifunctional” HIT capacity, as are those who share technical support with other practices (OR=1.56*); being able to receive financial incentives was not as strongly associated with HIT capacity. Solo and small practices lagged behind larger practices in HIT adoption, though sharing technical support and being part of an integrated delivery system lessened the divide.

*Statistically significant with p<0.05

**Conclusions:** Progress is seen in electronic ordering and electronic information to manage patients and populations, yet challenges remain for health information exchange and patient engagement, both of which are part of the next stage of meaningful use. Technical assistance programs and being part of integrated delivery systems significantly increase physicians’ ability to achieve advanced HIT capacity.

**Implications for Policy, Delivery, or Practice:** Priority should be given to building a national technical assistance infrastructure (e.g., modeled after the extension program) to assist all physicians as they redesign their care delivery to take full advantage of HIT and achieve the national triple aim goals. Payment reform should provide appropriate incentives to support behavior change as well as system redesign and sustainability.

**The Relationship of Online Health Information Seeking with Health Care Access and Health Status**

Neeraj Bhandari, Penn State; Kyoungrae Jung, The Pennsylvania State University; Yunfeng Shi, The Pennsylvania State University

**Presenter:** Neeraj Bhandari, Ph.D. Student, Health Policy and Administration, Penn State, nwb5090@psu.edu

**Research Objective:** The Internet plays an increasingly important part in disseminating public reports of health care related quality information and in facilitating consumers’ active roles in improving their health. A better understanding of online health information seeking behavior of particular groups of individuals, (e.g., those facing barriers to health care access and those suffering from chronically illnesses) may provide important insights on health policy designed to reach these constituencies. The aim of this study is to examine how consumers’ financial and non-financial barriers to healthcare access and their health status are related to online information seeking behavior.

**Study Design:** A cross-sectional design that uses the National Health Interview Survey (NHIS) of 2009, which is an annual survey representative of the non-institutionalized adult population of the United States, with oversampling of Black, Hispanic, and Asian populations. The survey collects information on a broad range of health topics through in-person household interviews. Multivariate regression analysis was used to examine the relationship of online health information seeking behavior with
limitations in access to health care, self-rated health status and presence of chronic disease, using a two-step empirical model to first examine health information seeking in the general population, and then examine the use of chat groups and e-mails to physicians among online health information seekers.

**Population Studied:** National Health Interview Survey (NHIS) of 2009, which is an annual survey representative of the non-institutionalized adult population of the United States.

**Principal Findings:** We found that individuals who had limitations in access to health care due to financial and non-financial reasons, those with chronic conditions, and those with higher self-rated health status were more likely than those without to search for health related information on the internet. Among health information seekers, people who face non-financial barriers to access to health care and those who rate their health status poorly are more likely than those without to join chat rooms and communicate with their physicians via email.

**Conclusions:** Our finding suggests that the Internet offers low cost access to health information for people with limited access to traditional channels of health care and for chronic disease patients.

**Implications for Policy, Delivery, or Practice:** Internet is a potentially low cost, although certainly imperfect, venue for delivering health information to the subset of population that faces difficulties in accessing care. Individuals with poor self-ratings of health, a group that has elevated level of risk for adverse health outcomes, could be an important target group for consumer engagement efforts directed at providing specific and individualized health information to consumers via the Internet.

**Improving Quality of Low-Performing Physicians: Lessons for Regional Extension Centers**

Samuel Boas, Weill Cornell Medical College; Tara Bishop, Weill Cornell Medical College; Andrew M. Ryan, PhD, Weill Cornell Medical College; Lawrence P. Casalino, MD, PhD, Weill Cornell Medical College

**Presenter:** Samuel Boas, Weill Cornell Medical College, sjb2010@med.cornell.edu

**Research Objective:** Regional Extension Centers (RECs) support the implementation of electronic health records (EHRs). Little is known, however, about how RECs should structure their support. The purpose of this study is to understand how EHRs and technical assistance (TA) from an REC helps low-performing providers improve quality of care.

**Study Design:** Qualitative study

**Population Studied:** We performed a qualitative study of physicians enrolled in the Primary Care Information Project (PCIP), a program of the New York City Department of Health and Mental Hygiene. PCIP subsidizes EHRs and provides ongoing TA to small primary care practices in underserved areas of New York City. It is the largest community-based EHR extension system in the country and is a nationally-recognized REC.

We identified physicians who had low baseline performance (bottom 50% of physicians) on 10 Healthcare Effectiveness Data Information Set (HEDIS) quality measures that were derived from claims data from 13 private payers in New York State. Among these physicians, we identified those who either showed significant improvement in quality after enrolling in PCIP (n=11) or showed significant decline in quality after enrolling in PCIP (n=21). Seventeen physicians agreed to be interviewed. Two investigators coded interview notes using the constant comparative method.

**Principal Findings:** All physicians stated that the EHR improved the quality of care they delivered. Several stated that the EHR specifically helped their management of chronic diseases and their delivery of preventative care. Eleven physicians used the EHR’s clinical decision support system (CDSS). The majority of physicians using CDSS found it to be helpful but some suggested improvements such as better customization for pediatric patients.

Seven physicians stated that the ability to track patients was a key reason why the EHR helped them to improve quality. Eleven used registries to help with tracking; however the majority did not have a system in place to regularly review registry data.

All physicians found TA visits to be useful. Several commented that TA helped them meet meaningful use and PCMH measures. Over half of the physicians wanted more technical assistance, particularly after they had been using the EHR for months or years. We found no consistent differences in responses from physicians whose quality improved from those whose quality declined.
Conclusions: This study stems from our previous work which showed that EHR use was associated with significant improvements in quality of care, particularly for physicians who had many TA visits. We identified three key themes: 1) every physician – regardless of whether their quality of care actually improved after enrolling in PCIP – felt that the EHR improved the quality of care they deliver to their patients, 2) every physician felt that technical assistance from PCIP was very useful and, in some cases, critical to their success in adopting the EHR, and 3) over half of the physicians wanted more, ongoing technical assistance, particularly during the months and even years after they had overcome the initial hurdles of implementing the EHR.

Implications for Policy, Delivery, or Practice:
These are important findings for other RECs that are considering ways to assist physicians in small practices in their use of EHRs.

Implementation of a Comprehensive Electronic Health Record System within a Patient-Centered Medical Home - Practice Changes and Challenges
Anne Bozack, New York Academy of Medicine; Angela Coral, BA, Center for Evaluation and Applied Research, New York Academy of Medicine; Diane Hauser, MPA, Institute for Family Health, Mount Sinai Icahn School of Medicine; Linda Weiss, PhD, Center for Evaluation and Applied Research, New York Academy of Medicine; Neil Calman, MD, Institute for Family Health, Mount Sinai Icahn School of Medicine

Presenter: Anne Bozack, M.P.H., B.A., Project Director, Center for Evaluation and Applied Research, New York Academy of Medicine, abozack@nyam.org

Research Objective: Medical practices are increasingly utilizing health information technology in response to meaningful use incentive programs and to improve health service delivery. An electronic health record, EHR, was implemented by a network of federally qualified health centers in New York State beginning in 2002, with development continuing during its transition to a patient-centered medical home, PCMH, in 2009. Components of the EHR system included physician decision supports, eprescribing, disease registries, quality tracking, and enhanced patient and provider access to medical information—as well as enhanced electronic access to one another. As part of a larger research project on the PCMH transition process, this study focuses on the EHR, with a primary emphasis on organizational changes and adaptations necessitated by and resulting from EHR implementation.

Study Design: Within a larger mixed-methods study, qualitative open-ended interviews were conducted between January 2011 and April 2012 with leadership, administrators, providers, and staff with diverse roles in the inception, planning, and application of the EHR. Topics included implementation processes, practice changes, and barriers, facilitators, and overall satisfaction with the EHR. Interview transcripts or notes were coded using a hierarchical set of codes and analyzed using standard qualitative techniques. Analyses included pre-identified themes, derived from literature and experience, as well as themes emerging from the data.

Population Studied: Thirty-three staff members were interviewed. Respondents were predominantly physicians, n=14, but also included nurses/medical assistants, n=5, behavioral health providers, n=4, administrators, n=4, and practice managers/patient service representatives, n=6.

Principal Findings: The FQHC EHR system was designed to improve the quality and efficiency of health care delivery, so as to improve services and outcomes for all patients. Interviewees reported that the implementation and effective utilization of the EHR did present clear benefits, as well as ongoing challenges. For example, expanded responsibilities for nurses and medical assistants created efficiencies overall, but were often difficult to manage, given the limited time allocated for office visits. Physicians also noted time related challenges, specifically a need for more administrative time for reconciling patient records and responding to electronic communication from other providers and patients. Despite these concerns, EHR implementation created a number of efficiencies and facilitated improvements in care. Physician decision supports helped providers to better structure the content of office visits, particularly for patients with complex conditions, and the ease of provider-provider communication promoted better coordination of care, including coordination of primary care and mental health services. Some patient inquiries, which would otherwise require an office visit, were resolved.
through communication using the patient portal, enhancing patient access to information while reducing the need for in-person visits.

**Conclusions:** The implementation of an EHR within a PCMH created opportunities for improved patient care and efficiencies, but required organizational changes.

**Implications for Policy, Delivery, or Practice:** Institutions must understand the need for - and benefit of - the reallocation of staff responsibilities and time outside of office visits. Enhanced reimbursement for models that emphasize use of EHRs, like PCMH, should allow for necessary shifts in workflows and responsibilities.

**A Predictive Model for High Costs Following Occupational Injuries**
Renan Castillo, Johns Hopkins Bloomberg School of Public Health; Jordan Hoolachan, Johns Hopkins Bloomberg School of Public Health; Tracy Mroz, Johns Hopkins Bloomberg School of Public Health; Anthony Carlini, Johns Hopkins Bloomberg School of Public Health; Sara Heins, Johns Hopkins Bloomberg School of Public Health; Arianna Perra, Johns Hopkins Bloomberg School of Public Health; Kristin Archer, Vanderbilt University School of Medicine; Stephen Wegener, Johns Hopkins School of Medicine

**Presenter:** Renan Castillo, Ph.D., M.S., Assistant Professor, Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, rcastill@jhsph.edu

**Research Objective:** Work-related disability and medical costs are a considerable burden to society and back pain is the largest contributor to this burden. There is a need to understand what claims characteristics are associated with high-cost claims, and to develop tools that make it possible to target high-risk individuals with additional medical care and psychosocial interventions. The availability of large claims datasets and computerized claims management systems make it possible to create screening systems to improve an insurers’ ability to identify individuals at risk for high costs following occupational injuries. The goal of this project was to develop and evaluate such a model based on data available within the first 24 hours of injury.

**Study Design:** This study is a secondary analysis of claims data. Claims were dichotomized as high or low cost and multiple imputation techniques were used to account for missing data. Multiple variable logistic regression models were developed and tested in two separate, randomly selected datasets. A single model was developed for all injuries, then evaluated on claimants with all injuries, and claimants with back injuries only.

**Population Studied:** Claims data from 1998 through 2008 from a large workers’ compensation insurance carrier in a single Mid-Atlantic state in the United States.

**Principal Findings:** A cutoff for high cost claims was selected such that high cost cases accounted for 10% of claims but 90% of total compensation in the overall population. The main predictors of high cost claims used in our model were higher age, higher wages, attorney involvement, hospitalization, treatment in emergency room and divorced, widowed, or separated marital status. In the overall population, the predictive model identified high and low cost cases with 90% sensitivity and 90% specificity. Among claimants with back injuries, the same predictive model identified high and low cost cases with 89% sensitivity and 85% specificity.

**Conclusions:** It is possible to accurately predict high-cost cases based on information available within 24 hours of injury. Although the model was developed for all injuries, it still performed well when used only on claimants with back injuries.

**Implications for Policy, Delivery, or Practice:** Similar modeling can be used to predict future costs, allocate administrative resources, and target interventions to high-risk claimants. Models that predict high cost patients based on information available within 24 hours of injury are especially useful to healthcare providers as they allow targeted, early intervention.

**The Neglected Social Component of the Meaningful Use of Health Information Technology**
Chung King Chia, Tan Tock Seng Hospital; Issac Lim, National Healthcare Group

**Presenter:** Chung King Chia, Associate Dean, Tan Tock Seng Hospital, drchungking@gmail.com
Research Objective: The debate regarding health information technology (HIT) has very much moved from whether information technology should play a part in health care, to what form it should take in the larger agenda of care delivery reform. The Health Information Technology for Economic and Clinical Health provisions of the 2009 American Recovery and Reinvestment Act allocated close to $US30 billion to encourage meaningful use of electronic health records (EHRs). Largely missing in the HIT and meaningful use conversation is HIT’s impact on the social component of the clinical environment. This study focuses on visualizing the communication patterns in a setting in which HIT has been fully implemented for close to a decade. We ask the question, how do communication patterns look like with HIT in the picture?

Study Design: We conducted 120 hours of participant observation and coded a segment of the data into adjacency matrices to perform social network analysis (SNA). Using UCINET, we calculated and compared the size of networks, average degree, and density of three clinical units. To create visualizations of the social structures and the communication patterns, we created sociograms using Gephi, an open source software for graphs and network analysis. We then created videos of dynamic communication networks using the Social Network Image Animator (or SoNIA). We also computed the time doctors and nurses spent on communicating intra- and interprofessionally, as well as time spent with patients and on HIT.

Population Studied: We focused on observing interactions between doctors, nurses, patients, and their use of HIT in three clinical settings, namely general internal medicine, general surgery, and intensive care units, in a large public general hospital.

Principal Findings: Although the communication patterns differed across the three clinical units that we observed, several findings were largely consistent. Intraprofessional communication far exceeds interprofessional communication. Doctor-to-doctor interactions was between 13.7% and 35.5% of total time in the units, whereas nurse-to-nurse interactions was between 13.5% and 25.8%. Interprofessional interactions ranged between 0.7% and 6.8% of time in the units. Most strikingly, doctors and nurses spent between 20% and 39% of their time on HIT, less than the time they spent on patients, which was between 18.4% and 26.9%. Scrutinizing the sociograms and dynamic network movies, it was clear that HIT was, in social network terminology, the most central node in the communication networks.

Conclusions: The centrality of HIT in the communication patterns in clinical settings is unequivocal.

Implications for Policy, Delivery, or Practice: A combination of factors makes our observed phenomenon noteworthy. First, our data strongly suggests that HIT has supplanted instead of facilitating face-to-face interprofessional communication. Second, the research on computer-mediated communication (CMC) often reveals the tendency for miscommunication because of its lack of social cues. Third, The Joint Commission found that 80% of serious medical errors involve miscommunication between caregivers and when patients are transferred or handed-off. Putting these three factors together, it is urgent that we include the impact of HIT on the social component of clinical environments in our conversations and research. HIT is a double-edged sword that comes with affordances and constraints. The potential of HIT in facilitating team work and close coordination is tremendous, but we have barely begun to think about it in enough details.

Health Information Technology use among Adults in the United States, 2009 and 2011

Robin Cohen, National Center for Health Statistics; Vaishali Patel, DHHS Office of the National Coordinator for Health Information Technology; Michael Furukawa, DHHS Office of the National Coordinator for Health Information Technology

Presenter: Robin Cohen, Ph.D., M.S., Statistician, Division of Health Interview Statistics, National Center for Health Statistics, rcohen@cdc.gov

Research Objective: Although recent trends suggest that adults’ use of health information technology (HIT) is increasing, adults’ access to and usage of their electronic health information has been relatively low overall. In 2009, the HITECH Act was passed to promote and expand the use of HIT. Federal programs began that sought to increase physician adoption of electronic health records (EHRs), including financial incentives for physicians who
demonstrated meaningful use of EHRs. As a part of demonstrating meaningful use, physicians need to electronically engage with patients, including providing access to electronic health information. This has the potential to increase adults’ own use of HIT. We sought to examine variation in adults’ HIT use since 2009 in five specific areas: using the computer to look up health information on the Internet, fill prescriptions, schedule appointments with health care providers, communicate with health care providers by email, and use online chat groups to learn about health topics.

**Study Design:** This study used data from the 2009 and 2011 National Health Interview Survey (NHIS), which is nationally representative of the U.S. civilian noninstitutionalized population, to examine the use of HIT for adults aged 18 years and over. Data were derived from the NHIS Family Core component, which collects sociodemographic information on all family members in each household, and the Sample Adult component, which collects additional information (including HIT information) from one randomly selected adult per family. In addition to NHIS data, county level data from the Health Resources and Services Administration Area Resource File on provider coverage and Federal Communications Commission data on broadband coverage and competition were used in the analysis.

**Population Studied:** Civilian non-institutionalized resident adult population of the United States (n=60,745).

**Principal Findings:** This paper will analyze the association between HIT use among adults and the following factors: selected demographic characteristics; usual source of healthcare; healthcare utilization; chronic health conditions; health status; and county level information on broadband coverage and provider coverage. Preliminary findings regarding the associations between demographic characteristics and HIT use show that among adults aged 18-64, women were more likely than men to use computers to look up health information on the Internet, fill prescriptions, schedule appointments with health care providers, communicate with health care providers by email, and use online chat groups to learn about health topics. However, among adults aged 65 and older, women were less likely than men to do each of these activities. Higher HIT use was also associated with higher incomes, education, and living in urban areas. Preliminary analyses are still underway to examine the association between the other key factors and HIT use.

**Conclusions:** Adults’ overall use of HIT has grown since 2009, and usage varies by demographic characteristics.

**Implications for Policy, Delivery, or Practice:** NHIS can play an important role in monitoring HIT use as policy changes take effect that seek to improve adults’ access to their electronic health information and electronic engagement with their providers. Identifying potential variation in adults’ use of HIT will be important in order to ensure that the potential benefits of HIT are widely available.

**Patient-facing Kiosks to Support Quality Improvement at Mental Health Clinics**

Amy Cohen, Greater Los Angeles VA Healthcare Center; Matthew J. Chinman, PhD, Pittsburgh VA Healthcare Center and RAND; Alison B. Hamilton, PhD, MPH, Greater Los Angeles VA Healthcare Center and UCLA; Fiona Whelan, MS, UCLA; Alexander S. Young, MD, MSHS, Greater Los Angeles VA Healthcare Center and UCLA

**Presenter:** Amy Cohen, Ph.D., Psychologist, Mental Illness Research, Education, and Clinical C, Greater Los Angeles VA Healthcare Center, ancohencan.ucla.edu

**Research Objective:** Obesity and related medical disorders are common in people with serious mental illness. This population dies 10 – 20 years prematurely, largely because of cardiovascular disease. Psychosocial weight loss interventions for this population are efficacious; yet, these interventions are rarely utilized by patients. This gap in care has been perpetuated by a lack of routinely collected data on patients’ clinical status and treatment utilization. However, routine data collection can be completed by these patients, especially when aided by health information technology (HIT) that is adapted for populations with cognitive deficits, limited literacy, and little computer experience. It is not known whether such patient reported outcomes data can be used to improve care quality.

**Study Design:** In a controlled trial, eight medical centers of the Veterans Health Administration were assigned to intervention or usual care for 13 months. The intervention included evidence-based quality improvement...
strategies including data from patient-facing kiosks, continuous data feedback, education, clinical champions, social marketing, and quality improvement teams. The kiosks, which were located in waiting rooms next to a scale, included a touchscreen monitor, computer, headphones and a color printer. At every clinic visit, before seeing the clinician, patients responded to kiosk questions regarding weight and service utilization. A Summary Report printed following the last question, which patients used at their clinical encounter. Mixed methods evaluated the impact of the kiosks on utilization of and retention in weight services.

Population Studied: 571 patients with schizophrenia who were overweight and had not used weight services.

Principal Findings: The majority of patients (80%) were overweight and the average body mass index fell in the obese range. In the year prior to baseline, rates of having at least 1 weight service appointment were low and comparable at implementation (13%) and control (18%) sites (p>.05). Compared with usual care, implementation resulted in individuals being more likely to use weight services (R2 = 10.5, p<.01), getting services more than 5 weeks sooner (t=2.0, p=.05), and using 3 times more visits (t=-4.6, p<.01). When compared to the year prior to implementation, patients at implementation sites saw a three-fold increase in treatment visits. Usual care resulted in no change from the previous year.

In terms of acceptability, the majority of patients responded affirmatively that they enjoyed using the kiosks (76%) and liked getting a Summary Report (71%). Patients noted that kiosk questions promoted self-reflection: “It asked questions that made you think about changing things about yourself;” “It kept me in check with myself;” “I like talking and being heard; I got a lot out of my system.”

Conclusions: In specialty mental health, obesity is a pervasive problem, but only a small proportion of patients receive appropriate services. Evidence-based quality improvement is possible, can be supported by HIT, and can lead to substantial increases in the use of appropriate services.

Implications for Policy, Delivery, or Practice: Patient-facing kiosks are feasible, acceptable, and inexpensive to implement. Such kiosks could be implemented in primary care or specialty clinics to identify patients’ needs, preferences, and utilization and those data could drive referrals and prioritization of services offered.

Identifying Medication Discrepancies Through Linked Administrative Pharmacy Claims

Dominique Comer, Jefferson School of Population Health; Joseph Couto, Jefferson School of Population Health; Ruth Aguiar, Christiana Care Health System; Edward Ratledge, University of Delaware; Daniel Elliott, Christiana Care Health System

Presenter: Dominique Comer, Pharm.D., Postdoctoral Research Fellow, Jefferson School of Population Health, dominique.comer@jefferson.edu

Research Objective: Medication reconciliation can be used to identify medication discrepancies between what a clinician has documented and what a patient is actually taking. Dramatic improvements in the availability of administrative pharmacy claims in the electronic health record (EHR) may facilitate accurate medication reconciliation, particularly in the ambulatory care setting. The objective of this study is to identify and characterize medication discrepancies through the use of linked pharmacy claims data.

Study Design: We conducted a retrospective cross-sectional study on all patients prescribed a new antihypertensive within a large primary care practice network from 2011-2012. Patients were included if they had a diagnosis of hypertension or elevated blood pressure at the time of the new prescription and at least one visit within the previous 18 months. We excluded patients who had not had an imported pharmacy fill history on or after the index visit date. Additionally, we excluded patients who did not have evidence of at least one claim in the pharmacy fill history prior to the index visit date. All pharmacy claims within the 120 days prior to the new prescription were compared to the medication lists from the EHR. Prescribed medications were considered active if the prescriber’s history showed that the medicine was still to be taken at the time of the index visit. The primary outcome was the number of medication discrepancies, defined as a medication that appears on either the EHR medication list or the pharmacy fill claims list but not both. Differences in dose were not considered for this study.
Population Studied: 611 patients prescribed a new antihypertensive in 2011-2012 within a large primary care practice network. The average age (SD) was 58.3 years (14.0), 61.5% were female, 24.2% of patients were black, 54.8% were white, and 19.3% were of another race or undetermined.

Principal Findings: There were a total of 4602 active medications in the EHR prescribed lists (average of 7.5 medications per patient) and 2854 medications in the fill history (average of 4.7 medications per person). Of the active medications in the physician list, 2083 (45.3%) were matched to a claim in the pharmacy fill history; the remaining 2519 (54.7%) were not matched to a medication in the physician list. Overall, patients had an average (SD) of 5.4 (4.3) medication discrepancies. Of the unmatched medications found in the pharmacy fill history, 139 (18.1%) were controlled substances.

Conclusions: In our cohort we identified frequent medication discrepancies between the pharmacy fill history and the prescriber's record. Importantly, there was a high prevalence of medications that patients had filled that were not recorded in the prescribing record, of which many were controlled substances.

Implications for Policy, Delivery, or Practice: The real-time availability of pharmacy fill history to providers in clinical practice has the potential to dramatically enhance medication reconciliation by providing objective documentation of what a patient is filling at the pharmacy. Our findings suggest that the availability of pharmacy claims may provide valuable information to providers as they conduct medication reconciliation.

Utilization of Health Care Services and Costs among Medicaid Recipients Seeing Primary Care Providers Participating in a City-Sponsored EHR Subsidy Program
Samantha De Leon, New York City Department of Health & Mental Hygiene; Sarah C. Shih, New York City Department of Health & Mental Hygiene, Primary Care Information Project(PCIP); Jason J. Wang, New York City Department of Health & Mental Hygiene, Primary Care Information Project(PCIP)

Presenter: Samantha De Leon, Ph.D., City Research Scientist, Primary Care Information Project(PCIP), New York City Department of Health & Mental Hygiene, sdeleon@health.nyc.gov

Research Objective: Compare the costs and health care utilization patterns of patients whose primary care providers are participating in the Primary Care Information Project (PCIP) to patients whose primary care providers are not participating in the program. PCIP is a quality improvement initiative targeting medical offices with high levels of Medicaid and uninsured patient populations and focusing on chronic disease prevention/management by facilitating the implementation of an electronic health record that promotes preventive care and improvement of population health.

Study Design: Using Medicaid claims data, patients were assigned to the PCIP or non-PCIP primary care group, total volume of health care costs were stratified by type of health service (i.e., hospital inpatient, emergency room, hospital outpatient, outpatient physician office visits, and specialty care services), calendar year and patient demographics such as age, gender and presence of major chronic diseases. Higher cost patients with cancer, HIV and end-stage-renal disease were excluded from the analyses. Mean values were compared for groups of patients by clinician between baseline year (2008) and end-of-study (2011). Cost estimates were further stratified by age and chronic conditions.

Population Studied: Fee-for-service Medicaid beneficiaries, excluding dual eligible beneficiaries, with at least one primary care visit in 2008 and another visit from 2009-2011 in New York City. Patients had to have all primary care visits with either a PCIP or non-PCIP primary care provider (i.e., family medicine, general medicine, internal medicine, geriatrics, obstetrics and gynecology, or preventive medicine). Approximately 274,000 patients were assigned to the PCIP group and 263,000 patients were assigned to the non-PCIP group representing 2,300 PCIP and 8,000 non-PCIP primary care providers.

Principal Findings: For patients 40-64 years, with at least one chronic condition, PCIP patient costs were higher at baseline ($4,606 per PCIP patient compared to $4,245 per non-PCIP patient). However, PCIP patients had a slower rate of increase in costs over time. Total costs increased by 17.4% ($801/patient) for PCIP patients and 19.4% ($821/patient) for the non-PCIP patients from 2008 to 2011. Hospital
inpatient costs had the largest increases over time, with PCIP patients having a slower rate of increase in costs. For example, PCIP patients with diabetes had a 39.3% increase of $8,416/patient whereas non-PCIP patients had an increase of 79.0% of $12,921/patient. With the exception of ischemic heart disease and the other four chronic conditions reviewed, PCIP patients had lower cost increases. **Conclusions:** Both the PCIP and non-PCIP groups had increased health care costs over time. Although at baseline, PCIP patients had higher health care costs, they had smaller increases over time, particularly for inpatient services. While we expected that the high proportion of Medicaid and uninsured patients at PCIP practices would result in less efficient care, results of this study suggest that a prevention-oriented focus to health care may have a positive impact on health care costs over time. **Implications for Policy, Delivery, or Practice:** As health care costs continue to increase, further research is needed to understand how quality improvement initiatives and information technology can decrease health care utilization and costs without adversely affecting patient quality-of-care. **Funding Source(s):** No Funding **Poster Session and Number:** A, #360

### Expanding the Use of Free Text in EMR to Study Breast Cancer

Caprice Greenberg, University of Wisconsin; Marquita Decker, University of Wisconsin; Christopher Dodgion, MD, MBA, MPh, Wisconsin Surgical Outcomes Research Program, University of Wisconsin; Thien Nguyen, BS, Massachusetts Veterans Epidemiology Research and Information Center (MAVERIC), Cooperative Studies Coordinating Center, VA Boston Healthcare System; Wei Jiang, MSc, Center for Surgery and Public Health, Department of Surgery, Brigham and Women’s Hospital; Yue-Yung Hu, MD, MPH, Department of Surgery, Beth Israel Deaconess Medical Center and Center for Surgery and Public Health, Brigham and Women’s Hospital; Anita Karcz, MD, MBA, Institute for Health Metrics; Stuart Lipsitz, ScD, Center for Surgery and Public Health, Department of Surgery, Brigham and Women’s Hospital; Leonard D’Avolio, PhD, Massachusetts Veterans Epidemiology Research and Information Center (MAVERIC)

**Presenter:** Marquita Decker, MD, General Surgery Resident, School of Medicine and Public Health, University of Wisconsin, mdecker@uwhealth.org

**Research Objective:** Data sources to study breast cancer care in large populations are limited by access to cancer-specific variables. We sought to address this gap by developing a validated, reusable approach to extract cancer-specific variables from the free text of electronic medical records (EMR) in a large cohort of US community hospitals. **Study Design:** Free text documents were received as a single XML file per patient, which was first parsed into individual documents (N=103,106). Randomly selected documents (N=1,597) were reviewed and classified by two independent surgical reviewers, with a breast surgical oncologist adjudicating disagreement. A portion of the adjudicated data set was used to train an open-source machine learning-based software to identify all breast cancer related operative reports, clinic notes, and pathology reports. The software was also used to further classify operative reports as diagnostic or therapeutic. Extraction of cancer-related variables from those documents was performed using a rules-based approach. Training sets of 200 pathology and 150 clinic notes and test sets of 50 of each were randomly selected. Two independent reviewers coded 8 concept-level variables with a similar adjudication process. Inter-rater reliability (IRR) was assessed using Cohen’s kappa (k). Computer performance was assessed using recall, precision and f-measure. **Population Studied:** An analytic cohort of 5,194 patients (11,022 encounters) from a nationwide cohort of 59 community hospitals was identified. Each patient underwent a breast procedure between January, 2006 and December, 2009 and had an available electronic operative report. **Principal Findings:** Classification of breast cancer-related document type: The abstracter IRR was 0.96 for identification of pathology reports, 0.86 for clinic notes, and 0.91 for operative notes. Computer performance was strong with recall of 0.95, 0.96, and 0.91; precision of 0.95, 0.88, and 0.85; and f-measure of 0.94, 0.91, and 0.87 for pathology, clinic, and operative notes respectively. A total of 2,055 pathology reports, 25,714 clinic notes, and 15,131 operative reports were ultimately identified. The computer identification of therapeutic operative notes showed similar high performance (0.96 recall, 0.93 precision, 0.94 f-
meanings). Concept-level Classification: IRR between manual reviewers for clinic notes ranged from 0.94 for tumor (T) and nodal (N) stage to 0.97 for tumor grade and 1.0 for estrogen receptor (ER) status with similar performance for pathology reports. Computer performance was more variable. Recall was high (1.0) for T and N stage, and grade, but lower for AJCC stage (0.95), ER (0.86), PR (0.90) and Her-2-neu (0.84) status. Precision was high (1.0) for T stage, PR and Her-2-neu status, but lower for N stage (0.92), AJCC stage (0.88), and grade (0.75). F-measures ranged from 0.86 for grade to 1.0 for T stage.

Conclusions: We have demonstrated the ability to reliably abstract several cancer-specific variables from the free text of EMR notes in a large cohort of US community hospitals. With further refinement, we anticipate improvement in performance for the others.

Implications for Policy, Delivery, or Practice: This new data source can be used for future comparative effectiveness and other health services research in breast cancer. Given the large, diverse set of hospitals, the approach is scalable and generalizable and can be modified for future research questions.

What Type of Hospitals Have Achieved Meaningful Use?
Mark Diana, Tulane University; Christopher A. Harle, University of Florida; Timothy R. Huerta, The Ohio State University; Eric W. Ford, University of North Carolina, Charlotte; Nir Menachemi, University of Alabama, Birmingham

Presenter: Mark Diana, Ph.D., M.B.A., M.S.I.S., Assistant Professor, Health Systems Management, Tulane University, mdiana@tulane.edu

Research Objective: The government has released the names of hospitals that received Medicare EHR incentive payments through November of 2012 under the Health Information Technology for Economic and Clinical Health (HITECH) Act. The objective of this study is to examine the characteristics of hospitals that have received Medicare EHR incentive payments.

Study Design: We used data from the Centers for Medicare and Medicaid Services, the American Hospital Association Annual Survey of Hospitals, and the American Hospital Association EHR Adoption Database. We conducted a logistic regression to examine the relationship between hospital and market characteristics and the likelihood of receiving Medicare EHR incentive payments through 2012. Hospital characteristics included hospital size, ownership, region of the country, teaching status, geographic location (rural versus urban), system membership, and accreditation status in the Joint Commission. In addition, we obtained information from the AHA Annual Survey on whether (1) the hospital is eligible for Medicaid incentive payments (measured as having 10% or larger share of Medicaid discharges), and (2) the proportion of hospital inpatient days billed to Medicare (Medicare caseload). We calculated EHR adoption status in 2010 (prior to the start of the program) and whether the hospital had a single EHR vendor using the AHA EHR Adoption Database. We calculated market concentration at the hospital system level using the Herfindahl-Hirschman Index (HHI).

Population Studied: The final sample consisted of 5,888 hospitals, with 959 (16%) of these having received Medicare MU incentive payments through November 2012. Of these hospitals, 2,955 (50%) provided information on their EHR status in the AHA EHR Adoption Database, and 653 (22%) of these received Medicare MU incentive payments.

Principal Findings: Overall, 16% of hospitals achieved meaningful use and received incentive payments. When examining the characteristics of hospitals that received these payments, we found that hospital size, for-profit tax status, and presence of an EHR system in 2010 (1 year prior to the commencement of the incentive program) were associated with achieving meaningful use. System hospitals and those located outside of the Northeast were less likely to receive incentive payments.

Conclusions: The main finding of our analysis is that adoption of EHR before the start of the incentive program was the strongest predictor of achieving MU. A little over one-half of hospitals with a comprehensive EHR in 2010 earned a MU payment by November 2012. An increase in Medicare share was positively associated with achieving MU.

Implications for Policy, Delivery, or Practice: Thus far, there is little evidence to suggest that the HITECH incentive program has enticed hospitals without an EHR system to adopt and achieve MU. This raises the concern that the EHR incentive program may not rapidly achieve the intended goal of widespread EHR MU,
which, because of low national EHR adoption rates, must be driven by new EHR implementations. On the other hand, the goals of reducing Medicare costs by providing greater incentives to high-volume Medicare hospitals may be having the desired impact. Policy makers should consider modifying the inventive program to accelerate the adoption and meaningful use of hospitals without EHRs.
